THE ENCYCLOPEDIA AMERICANA

O

ORLEY, ôr'li, **Bernaert** (BAREND, BERNHARD) van, Dutch painter: b. Brussels, about 1493; d. there, 6 Jan. 1542. He studied in Italy between 1509 and 1515 and imitated the Italian masters, especially Raphael. Returning to Brussels he was appointed court painter to Margaret of Parma (1515) and to her successor Maria of Hungary (1520). While he began his career as a follower of Gerard, David, he altered it after his Italian travels, but in his modeling and color scheme he never forsook the traditions of the Dutch school. His works indicate keen power of observation and a delicate perception of beauty in form and expression. Among the best of them are 'Scenes from the Life of Saint Thomas and Saint Matthew' (altarpiece), in the Imperial Museum, Berlin; 'Sorrows of Job' (triptych) in the Brussels Museum; 'The Flight into Egypt' (in the Liverpool Royal Institution); 'Worship of the Holy Trinity' (Lübeck, Saint Mary's Church), and 'The Holy Family' (in the Dresden Gallery). He also furnished designs for wall hangings which were executed in Brussels tapestry, of which there is an example in the Louvre, 'The Imperial Hunt,' executed for the Emperor Charles V.

ORLOFF, ôr-löf', a Russian noble family, founded 1689 by Ivan, who was condemned to death by Peter the Great, but pardoned for his bravery and coolness. His grandson GRIGORI (1734-83), fought in the Seven Years' War, became the paramour of Catherine II, to whom he gave the famous Orloff diamond, or Koh-i-Nur, weighing 193 carats, and now a crown jewel. But she dismissed him for Potemkin. His brother ALEXEI (1737-1808) plotted against Peter III, and in 1770 won the battle of Tchesme and the name Tchesmensky. The Orloff breed of horses is named after him and is a cross of his introduction into Russia. GRIGORI VLADIMIR (1777-1826) spent his last years in Paris, wrote in French on Italian history, and edited a polyglot Krylof. ALEXEI FEDOROVITCH (1781-1861), a general in the Napoleonic wars, and a famous diplomat, in 1833 effected the Treaty of Unkiar-Skelessi, giving Russia the sole right to pass the Dardanelles. His son NIKOLAI (1827-85) advocated religious toleration and the abolition of corporal punishment.

ORLOFF (ôr'löf) **DIAMOND**, The. See **DIAMOND**; **ORLOFF**.

ORLOP-DECK, in naval architecture, the lowest deck, consisting of a platform laid over the beams in the hold of a ship of war, whereon the cables were usually coiled, and containing also cabins and storerooms. In merchant vessels it is often a temporary deck. It was first applied to the single deck of a small vessel.

ORMAZD, ôr'măzd. See **ORMUZD**.

ORMEROD, ôr'mê-röd, **Eleanor Anne**, English entomologist: b. Sedbury Park, Gloucestershire, 11 May 1828; d. Saint Albans, England, 19 July 1901. She acquired her knowledge of entomology through her own investigations, devoting herself especially to the study of injurious insects. Her advice was sought, and specimens of harmful insects were sent her from all over the world. She was the first woman to be honoured with a fellowship in the Meteorological Society (1878), and with the degree of LL.D. of Edinburgh University (1900), and in 1882 was appointed honorary consulting entomologist to the Royal Agricultural Society. She published 'Cobham Journals' (1879); 'Guide to Insect Life' (1884); 'Annual Reports of Observations on Injurious Farm Insects' (1877 et seq.), etc. Consult the autobiography and correspondence, edited by R. Wallace (1904).

ORMOC, ôr-möck', Philippines, a pueblo of the island of Leyte, situated on the Bay of Ormoc, on the western coast of the island, 35 miles southwest of Tacloban. It is surrounded by a stone breastwork with three ruined forts. It has an important hemp trade. The Bay of Ormoc affords the only safe anchorage on the west coast of Leyte during typhoons. Pop. 8,200.

ORMOLU (French *or moulu*, "ground gold"), in the etymological meaning of the word, ground gold leaf used as a gilt pigment; and by an extension of the term a compound of copper, zinc and tin (sometimes called "mosaic gold"); or a paste of mercury and gold, used for gilding.

ORMOND, ôr'münd, **Alexander Thomas**, American philosophical writer: b. Punxsutawney, Pa., 26 April 1847; d. Grove City, Pa., 18 Dec. 1915. He was graduated at Princeton in 1877; was professor of philosophy and history in the University of Minnesota, 1880-83; of mental science and logic at Princeton, 1883-98; and McCosh professor of philosophy at the latter institution from 1898. He was president of

Grove City College from Aug. 1913 until his death. He published 'Basal Concepts in Philosophy'; 'Foundations of Knowledge' (1900).

ORMOND, Duke of. See BUTLER, JAMES.

ORMULUM, ôr'mû-lûm, in early English literature, an English metrical translation of the Gospel history. See ENGLISH LITERATURE.

ORMUZ, ôr'mûz, or **HORMUZ**, an island in the Persian Gulf, on the north side, near its entrance. It is about 12 miles in circumference, has a rugged appearance, is entirely destitute of vegetation, has several of the high peaks white from an incrustation of salt, and abounds in iron, copper-ore, and rock-salt. Ormuz was once the emporium of all the riches of India, the receptacle for the gems of Samarkand and Bokhara, and for the manufactures of Europe and Asia. The Portuguese had possession of it from 1515 to 1622, when it was captured by the English and given to the Shah of Persia, who dismantled the city, transferring its commerce to Bender Abbas, on the opposite coast. The town of Ormuz stood on a plain on the north side of the island; and although now only a few scattered ruins, it once contained 4,000 houses.

ORMUZD, ôr'mûzd, or **ORMAZD**, supreme deity, literally "Lord Wisdom," in the Zoroastrian religion. The word is a broken down form of the Avestan "Ahura Mazda" and the old Persian "Auramazda," and these three forms are interchangeable in modern usage. Ormuzd, in the Zoroastrian religion, is represented as the head of the heavenly host and the Lord of all that is good and true. He, however, shows his origin as a sun-god in that he is the great master of light. But even in the old Persian inscriptions he is depicted as the creator of all good, the distributor of rewards and punishments, and the beneficent guardian of mankind. As the religious ideas of the Persians progressed, Ormuzd is more and more represented as a wholly spiritual being; and in the 'Avesta' his spiritual attributes are constantly contracted with the non-spiritual attributes of Ahriman. Here was taking place exactly what was taking place in Egypt. One powerful divinity was gathering to himself all the better attributes of many of the primitive racial gods. There are traces of pantheism in the Persian religion even at a later date; but Ormuzd gained his ascendancy, not from this but from a dualism shared by him and Ahriman. He is the good principle, who is continually at war with Ahriman, the bad principle, and the Zoroastrian conception of him was a very noble one, free from any traces of anthropomorphism and from any recollections of nature worship. The influence of this concept on Judaism and Christianity was undoubtedly great, and Ormuzd approaches closely to Jehovah as a high type of the ideal of a national religion. (See AVESTA; ZOROASTER). Consult Darmästeter, 'Ormazd et Ahriman' (1887); Dhalla, M. N., 'Zoroastrian Theology from the Earliest Times to the Present Day' (New York 1914).

ORNAMENT. Derived from the Latin *ornare*, to adorn. The artistic embellishment of the work of craftsmen, especially in architecture and the industrial arts. Ornament consists of an additional refinement in beautifying a useful or decorative object. Its sphere is

strictly limited to the following confines: (1) The utility or purpose of the object ornamented must not be interfered with. (2) The ornamentation must be *fitting* to the object in style, construction and material. (3) The ornament must enhance the interest in the object, that is to say must *mean something* and not be a *purposeless* addition. (4) Ornament must not *hide* the nature of the article embellished. The form and style of ornament must be selected to be in accordance with the surface to which it is attached. The sources drawn upon to supply ornamental motifs consist chiefly of the following: Geometrical configurations, plant and animal forms, and (more rarely) the human figure. The surfaces available are, of course, in the flat or in relief. In the latter case *applied* ornament can be used, that is to say the ornament can be attached to the original finished object. Ornament, therefore, can be divided into three basic branches: High relief, low relief and flat. Another important element entering into the art of ornamentation is consistency in style, the avoidance of anachronisms in period decoration.

History.—Extreme simplicity of ornament is the general rule with prehistoric man, and also with the primitive peoples, in the decoration of their utensils and weapons. Thus we have paleolithic remains (especially from the south of France and Switzerland) from the period of the mammoth and reindeer, which exhibit ornament very similar to that characteristic of the huntsman and primitive tribes of the present day. Waved lines, concentric circles, spirals and uncouth figures are the main motifs. Ornament from the later Stone Age shows an advance in some points in the decoration, especially of pottery, and we get even colored ornament. The Bronze period brings us chiefly geometric ornament. The Early Iron Age has left us remains of plastic ornamental motifs of birds, horses, etc. Roman influence follows and we get the plant motifs of North Europe. In the Merovingian period (500–750) we already find ornament in colored glass pastes, colored stones set cloisonné. The excavations of Schliemann (Troy, Mycenæ, Tiryns) brought forth ornamented antiquities displaying geometric motifs (wave, zig-zag, spiral, etc.) peculiarly similar to Oriental ornament of the period, as also do those from Cyprus. Only gradually do we find the attempt made to represent animals with stiff lines; these are developed at last in the oldest ("archaic" style) Greek vases. With the Assyrians we find linear ornament (guilloches) and motifs borrowed from the vegetable kingdom, such as rosettes, blossoms, palmettes, etc. The same must be said of the ancient Egyptians, the lotus flower and aquatic plants prevailing. Alongside these came conventionalized animals (scarabs, the uræus snake, the sparrow-hawk). For textile ornament the Egyptians developed geometric patterns. But it is in Hellenic art that we discover the grandest scheme of ornamentation. Here ornament was developed to a systematic science, so that every decorated space received only that style of motif best suited for that special purpose, forming fixed types. Meanders and palmettes are the chief linear and vegetable ornament. The Etruscans advanced from the crude *impasto* to their *bucchero* ware

decoration using a roller with carved intaglio motifs to *string* out a continuous series of medallions or other "repeat" designs on their pottery. The Romans in their burial chambers (*columbaria*), on the walls of their country villas, and at Pompeii, etc., show their love of richly-colored mural ornament (Greco-Roman) in which the perfected human figure developed by the artists of Athens finds plentiful display. And it is from this ancient ornamental work (rediscovered in the 15th century) that the great Renaissance ornament grew. The Byzantine ornament, taken from the Oriental, was limited to vegetable and linear forms, relying for its attractions on the clever color contrasts. With the Arabs, Moors and Persians ornament relied on the late Greek and Byzantine elements brought out in great richness and fantasy. Oriental influence is seen also in the book ornament (*illumination*) of the old Irish and Russian monasteries. Much of the Persian decorative cult of the Middle Ages is derived from the East Indian, the Chinese and even the Japanese. And, it must be remembered, the art of the eastern Asiatics is chiefly one of ornament. In the 18th century this Oriental style influenced greatly European decoration. Going back again, the Greco-Roman ornament led to the Romanesque and ruled strictly in the architectural interiors from the 10th to 13th centuries. Taking its elements from a study of nature, it reproduced, in fantastic liberality, the animal figures which make up its system. With the arrival of the Gothic style we revert again to vegetable motifs chiefly, later to naturalistic depiction, degenerating soon to overloading and meaningless display. In Italy the Renaissance was utilizing the classic simplicity or the rich Greco-Roman ornament disclosed in the excavations of Pompeii. The beauty of the work was infectious and France and Germany, the Netherlands and later Spain were importing Italian artists to decorate the palaces with Renaissance ornament. But the dainty refinement of French artists naturally soon gave native qualifications to the Italian style and the Rococo came into being with all its light coquetry and fantastic figures and contortions. In Germany ornament degenerated into the Barock with its heavy ostentation. But the grace and playful lightness of Rococo gave place to the Louis XVI style with its return to the severe classic ornament, following, for the most part, a close imitativeness of the antique patterns. This again was followed by the "Empire style," even stiffer in ornament than the former. And with the 19th century we arrive at the outcome of the artist to cast aside the thralls of past styles and to achieve freedom of originality and genius. The French termed the period *Art Nouveau*, the German called it *Jugend* (Youth). With a few certain prominent exceptions the ornament was mediocre, tending to refinements perhaps or even vigor, according to the exponents. But *New Art* bids fair to be soon forgotten as an independent entity. Technique is mastered and prettiness effected often, but of master minds none has arisen.

Masters of Ornament.—Space forbids more than mention of a few of the "little masters" of the French styles and those artists who aided from their genius. To *Renaissance*

belong Ducerceau, Philibert Delorme, Étienne Delaulne (Stephanus), René Boivin, Pierre Woeriot. To *Louis XIII* style belong Vouet, Stella, Adam Philippon, Abraham Bosse, Gédéon Lesgaré, Jacquard, Toutin, Jousse. Leaders of the prolific *Louis XIV* style are Jean Lepautre, Charles Lebrun, Jean Marot, Daniel Marot, Charles André Boule, Jean Bérain, Gilles Lesgaré, Bernard Picard, Gribelin, Vauquer, Toro. To the *Regency* period belong Robert de Cotte, Gilles Marie Oppenort, Antoine Watteau, Claude Gillot. Leaders in the origination of the *Louis XV* style are Boffrand, Delajoue, Meissonnier, Cuvillières, Blondel, Eisen, Boucher, Pillement. *Louis XVI* style is largely due to Lacotte, Vien, Salambier, Quéverdo, Delafosse. And to Percier and Fontaine are chiefly due the *Empire Style*.

ORNAMENTAL PLANTS. See PLANTS.

ORNAMENTS RUBRIC. The, a rubric in the Book of Common Prayer about which there has been much controversy. It is set down as follows, just before the Order of Morning Prayer: "And here it is to be noted that such ornaments of the Church and of the ministers thereof, at all times of their ministration, shall be retained and be in use as were in this Church of England, by the authority of Parliament, in the second year of the reign of King Edward the Sixth." Ornaments in this connection have been defined by a Committee of the Privy Council as "all articles used in the divine service." The Puritan opposed the retention of the rubric in 1661, but it has remained despite powerful efforts to eliminate it. For the controversy regarding its interpretation see RITUALISM, and consult Parker, 'The Ornaments Rubric' (Oxford 1881).

ORNDORFF, William Ridgely, American chemist: b. Baltimore, Md., 9 Sept. 1862. He was educated at Baltimore City College and in 1884 was graduated at Johns Hopkins University. Subsequently he studied at the universities of Greifswald, Berlin, Heidelberg and Munich. In 1887-90 he was instructor in chemistry; in 1890-98 assistant professor of organic chemistry, in 1898 of organic and physiological chemistry and since 1902 professor of

organic and physiological chemistry at Cornell University. In 1890 Dr. Orndorff was special agent of the United States census and has served on the jury of awards at most international expositions of recent years. He is contributor to the *American Chemical Journal*, *Berichte der deutschen Chemischen Gesellschaft*, *Journal of the American Chemical Society* and the *Journal of Physical Chemistry*. He has published 'Laboratory Manual of Organic Chemistry' (1894) and a translation of E. Salkowski's 'Laboratory Manual of Physiological and Pathological Chemistry' (1904).

ORNITHODELPHIA. See MONOTRE-MATA.

ORNITHOLOGICAL SOCIETIES IN THE UNITED STATES, began with the formation of the Nuttall Ornithological Club in Cambridge, Mass., in 1872-73. The study of birds had been an important part, previously, of several societies and institutions for research, but only about Boston were there enough bird students at that time to form a special society, since the large group of ornithologists then resident at Washington was engaged in the more general field afforded by their biological society. Among the founders of the Nuttall Club were William Brewster, Ruthven Deane, J. A. Allen, H. A. Purdy, C. J. Maynard and Ernest Ingersoll. The club increased and have published occasional memoirs of value. This club was the prime mover in organizing, in 1884, the American Ornithologists' Union (ordinarily called "A. O. U."), patterned after similar organizations in Europe. Its fellows and members are limited to persons of a certain high standard of scientific attainment, while its "associates" include several hundred amateurs. Its annual open meetings are held in different cities, and are called "conferences"; while occasionally it participates in an international congress. The A. O. U. publishes *The Auk*, a quarterly of high scientific value, edited by J. A. Allen. Of more local character are such associations as the Delaware Valley Ornithological Club, founded at Philadelphia in 1890, which issues an annual publication, *Cassinia*, edited by Witmer Stone; the Cooper Ornithological Club (1893), which devotes itself to the bird-life of the Pacific Coast and Alaska; it has sections in San Francisco and Los Angeles, and publishes an illustrated magazine, *The Condor*, every two months, edited by Joseph Grinnell; the Maine Ornithological Society, founded in 1893 and centralized in Portland, which publishes a modest journal; the Nebraska Ornithologists' Union, begun in 1893 at the State University; the Wilson Ornithological Club, originating at Oberlin College, Ohio, and fostered by Prof. L. Jones, which issues a quarterly, *The Wilson Bulletin*, devoted to bird life in the Central States. In close connection with these, but devoting its energies to the protection of birds and the education of children, is the National Association of Audubon Societies (q.v.). Many local bird clubs, however, exist in the United States and in Canada, such as the McIlwraith Club, at London, Ontario, the Bird Lovers in Cleveland, Ohio, etc.

ERNEST INGERSOLL.

ORNITHOLOGISTS UNION, American. See AMERICAN ORNITHOLOGISTS UNION.

ORNITHOLOGY, the science which treats of birds. It is susceptible of such a broad interpretation that it is difficult to define its limits with accuracy, and of late years certain of its branches have become to such an extent matters of popular interest that we are coming to use the term "bird study" to distinguish them from purely scientific ornithology. Ornithology proper, then, may be said to treat of the classification of birds,—both the phylogeny of the group as a whole and the definition of the numerous species and varieties—which involves anatomical, morphological, embryological, and physiological investigations and studies of both the living and dead bird. Geographic distribution and migration also form important branches of ornithology, and though the former pertains equally to other branches of zoology, as well as to botany, it has nevertheless been studied very largely from the side of the birds.

Structure.—Birds, being eminently aerial, the anterior pair of limbs are modified into wings, and the bones of the hand are so much reduced that portions of two digits only remain. The peculiarities of feathers and other accessories to flight are described elsewhere. See FLIGHT; PLUMAGE.

Considering other peculiarities in the general structure of birds, we find the skull bones to be united to a remarkable degree, so that almost all traces of the components are lost. In the head of the adult bird, besides the skull proper and the lower jaw, are only four separate bones, excepting the hyoids that support the tongue. These are the two *quadrates*, which lie between the articulating surface of the lower jaw and the skull—a peculiarity of birds as compared with mammals, in which the mandibles articulate directly with the skull, and showing their closer alliance with reptiles; and the two *pterygoids*, which connect the quadrates with the palate. The skull is poised upon the spinal column by a single condyle, as in reptiles, and not by two condyles, as in mammals. The eye of birds is relatively very large, and the ear is situated rather below and behind it, but does not protrude externally and the situation of the opening is not noticeable, except for the slightly different sort of feathers that usually cover it. No living birds are provided with teeth, the mandibles being covered with a horny sheath forming the bill, which has sharp cutting edges, and is modified in form according to the habits of the various species. The feet of birds show even a greater degree of adaptive modification than the bill, and inasmuch as these two are the only parts of a bird not covered by feathers, it is not surprising that all the older classifications were founded almost exclusively upon them. The ankle bones (as well as the bones of the wrist) are lost very early in the development of the bird, and become entirely combined with the ends of the adjoining bones, so that the so-called tarsus, a fusion of all the tarsal bones, includes, in addition, the metatarsal elements, and is more properly known as the "tarsometatarsus." The fibula in most birds is more or less reduced, the lower portion ending in a sharp point, and not reaching the end of the tibia, as is familiar to us in the "drum stick"

of the chicken. The femur and a large portion of the tibia are covered by the skin of the body so that the entire external part of the bird's leg is in reality the foot, the long "tarsus" with its usual horny covering corresponding to the flat portion of the human foot, while the bend where the feathering begins is the heel. In other words, the average bird carries its heel high up in the air and walks or grasps with the toes, which are at the other end of a very long instep. The toes themselves are never more than four,—usually one directed backward and three forward, making a grasping foot. Sometimes, however, one of the front toes is reversed, as in the woodpeckers, or all may point forward, as in some swifts. Certain woodpeckers have but three toes, while all birds which habitually walk, and most of those that swim, exhibit a great reduction or total loss of the hind toe.

The modifications in webbing and other peculiarities of foot-structure are very numerous. Most swimmers have two webs, uniting the three functional toes, while the cormorants, pelicans, etc., in which the hind toe is well developed, have three webs.

The neck of birds is usually long, the vertebræ moving easily upon one another, so as to permit great flexibility. The body cavity is well encased by the bony structure, but owing to the length and construction of the ribs is likewise very flexible. Its most peculiar characteristic is the remarkable development of the sternum or breast-bone, which is expanded into a broad, flat structure. Sometimes, as in the ostriches and their allies (non-cerinate or ratite birds) it is smooth on the anterior surface, but in other living birds (carinate) it is provided with a vertical keel. It is to this that the great flight-muscles of the breast are attached; and while the presence or absence of a keel was formerly looked upon as of primary importance in tracing the ancestry of birds, it is now regarded more as an indication of the extent to which the power of flight has been lost. On the back of the body cavity is another solid, bony structure known as the sacrum, formed by the fusion of the lower vertebræ and the pelvis. The clavicles or "collar bones" of a bird also present a peculiar appearance, being usually firmly ossified at their lower extremities, forming a V-shaped bone known as the furculum or popularly the "wish-bone."

As to the soft anatomy of birds, a characteristic avian structure is seen in the thick-walled muscular gizzard, which is a prominent feature of the stomach of all birds which devour hard substances such as grain, horny insects, etc., though practically absent in birds of prey and fish-eating species whose food is soft. All birds with well developed gizzards swallow small particles of gravel, sand, etc., which by the action of the muscular walls grind up the food that they have swallowed and render it suitable for digestion, performing, as it were, the work of the molars or grinding teeth of mammals.

The complicated voice-organ or syrinx, comprising the lower portion of the larynx, is another organ peculiar to birds, and the arrangement and number of the muscles that contract the horny rings by which the vocal chords are controlled, have recently been found to be of fundamental importance in avian classification.

This organ is only highly developed in the singing birds (*Oscines*).

Classification.—Owing to the great amount of attention that has been devoted to systematic ornithology through long periods of years, we find that it is through this branch also that the "science" of nomenclature has reached its present formidable development. Although of equal importance to all systematists, it is the ornithologists who have been responsible for the earlier and the more important codes that have been formulated to govern the formation and adoption of our technical systematic names. From the time of Aristotle scientific literature has been full of attempts to classify birds. The earlier schemes naturally dealt with external characters only, and as feathers were common to all, the only available parts were the bill and feet. There were two grand divisions, Water Birds and Land Birds, while under these came the waders, swimmers, divers, etc.; the birds of prey, gallinaceous birds, *Fissirostres*, *Conirostres*, *Tenuirostres*, etc.

In 1813 Merrem proposed to separate the birds with a smooth breast-bone (ostriches, etc.) from the rest of the class—which all possess a keel on the sternum. This was an important advance, and the first recognition of the modern groups *Ratitæ* and *Carinatæ*. In 1827 a Frenchman, L'Herminier, made an extended study of the skeletal structure of birds and brought to light many points of relationship between birds hitherto regarded as distinct and vice versa. The cranes and herons were shown to be wrongly associated, and similarly the gulls and petrels, while the relationship between the gulls and the plover tribe was pointed out. Thus were the long accepted groups of "waders" and "swimmers" rudely shattered and the external resemblance in foot-structure was shown to be superficial.

The classification of birds, always a puzzle, now became still more complex, and all parts of the avian structure were investigated in the hope of reaching some set of characters that would prove the solution of the problem. The idea seemed to be then prevalent—and is still so in the minds of some systematists—that some one part of the bird's structure would furnish characters upon which a satisfactory classification could be established. Nitzsch made numerous anatomical investigations, but his most important discoveries were in connection with pterylography, showing that the number and shape of the feather-tracts differed widely in different groups. McGillivray and Müller studied the soft anatomy, and the latter was the first to divide the passerine birds into *Oscines* (singing birds) and *Clamatores*, by pointing out the difference in the number and character of the vocal muscles. Sundevall considered the physiological side of the subject and was the first to define Altricial and Precocial birds—those respectively that are hatched helpless and reared in a nest and those that run about as soon as leaving the egg. Up to this time classification meant a search for similarities with the object of arranging species in definite groups and families. In the minds of some the whole matter was one of mathematical exactness and in this connection the circular system outlined by Swainson in his 'Geography and Classification of Animals' is interesting reading. There now came a revolution in the classification of

birds, as well as of other groups. In 1859 Darwin published his 'Origin of Species,' and his work, as well as that of Alfred Russell Wallace, soon put classification in a new light. It was realized that the birds of to-day are the terminal branches of a great family tree of bird-life whose trunk and early limbs are far back in the geological past, where they merged into the trunk which has produced the modern reptiles. Some of our present bird-families, notably those most numerous in species, are comparatively recent developments, suited in every way to prevailing conditions; while others, usually with few representatives, are the remnants of ancient groups which belong much farther back on the tree, and have barely survived to the present time. The significance of fossil-forms now become evident, as well as the fact that birds could not be arranged in a lineal series and preserve their proper relationship. It was also clear that in tracing the phylogeny of birds all sorts of characters must be taken into consideration; since modification in one part may have been important at one time, or in one group, while in another group some other part was the seat of variation.

The principal contributors to the modern classification of birds are as follows:

Huxley in 1867 made a study of birds' skulls and demonstrated the importance of the arrangement of the bones of the palate, as an aid to classification, defining the several types of palate-structure known as dromæognathous, desmognathous, schizognathous and æthognathous. Garrod and Forbes made important additions to our knowledge of the muscular anatomy of birds and in 1888 Fürbringer published probably the greatest treatise on avian phylogeny that has yet appeared. One of his most important discoveries was that of the descent of the ostriches and their allies from flying ancestors, showing them to be a degenerate and not a primitive group.

In spite of the vast amount of attention that has been given to the subject, we are still far from solving the problem of avian classification. The great rarity of fossil birds leaves gaps in the system which it is almost hopeless to expect to fill; and although ornithologists are pretty well agreed upon a number of the leading groups, their exact phylogeny will remain a matter of guesswork unless comparative embryology shall solve the problem. It is a well-known fact in zoology that the embryonic development of the individual in the main represents the palæontological development of the species; and if embryo birds have been saved and studied by zoologists, instead of the empty shells of the eggs, we might to-day be much farther along on our way.

The present views of bird-classification are briefly as follows: We have two distinct branches of existing birds, the degenerate *Ratitæ* and the *Carinatae*. The former represented by four orders: 1, the *Apteryx*es of New Zealand; 2, the cassowaries and emus of the Australian region; 3, the rheas of South America; and 4, the ostriches of Africa and Arabia.

Among the *Carinatae* we have, first of all, the tinamous (*Crypturi*), a sharply defined group of birds recalling the gallinaceous type in external appearance, but with many points of re-

semblance to the *Ratitæ*. The penguins (*Sphenisci*) are a degenerate group of somewhat doubtful affinity, which Dr. Stejneger regards as differing more from any of the remaining birds than they do from each other; while other authorities place them as a distinct order, but in alliance with the loons. The latter, together with the grebes, form a natural order *Pygopodes*, while the petrels and albatrosses form another, *Tubinares*. The relationship of the auks (*Alcidæ*) has been in some doubt, but they are now most frequently placed near the gulls (*Gaviæ*). The latter have much in common with the plover and sandpipers (*Limicolæ*), and the sheathbill (*Chionis*) is in many respects intermediate; together with the bustard (*Otididæ*) they seem to form another natural order. Three other groups of "water" birds constitute well defined groups: (1) The *Anseriformes*, ducks and geese, with the outlying horned screamers (*Palamedea*) and flamingos; (2) the storks and herons; and (3) the *Steganopodes*, or totipalmate swimmers; that is, cormorants, pelicans, etc. The last-named bear affinity to the hawk-tribe (*Accipitres*), which, with the American vultures, form a distinct group, their only other alliance being a possible one with the herons through the secretary bird (*Serpentaria*). We have left the cranes (*Gruidæ*), rails (*Rallidæ*), and trumpeters (*Psophiidæ*), which form an order *Gruiformes*; and several very puzzling forms which are generally placed in the neighborhood of the rails, though they have no near relatives and some, at least, are generalized forms descended from earlier branches of the family tree and consequently exhibiting characters possessed by several distinct modern families. Such birds are the seriema, sun-bittern and kagu.

We next have the great gallinaceous assemblage, near which are placed the sand-grouse (*Pterocles*) and the pigeons (*Columbæ*). While that curious bird, the hoactzin, the representative of a distinct order, seems in some respects a connecting link between the gallinaceous type and the plantain-eaters (*Musophagidæ*), which stand near the cuckoos. From this point we pass to a number of groups, some of them very sharply defined, others less so; as, for instance, the woodpeckers (*Pici*), parrots (*Psittaci*), owls (*Striges*), whip-poor-wills, etc. (*Caprimulgi*), swifts (*Cypseli*), humming-birds (*Trochili*), etc. The complete separation of the owls from the hawks seems borne out by all modern researches and their true position is probably in the neighborhood of the *Caprimulgi*. Last of all come the *Passeres*, divisible into two sub-orders and comprising far more species than all the other orders combined, but so hopelessly are the species interrelated that only a very few clearly circumscribed families can be distinguished, of which the swallows (*Hirundinidæ*) are one of the best. Just which species of passerine birds are the highest; that is, the most specialized, is a matter concerning which there is much difference of opinion and the thrushes, crows and finches have each been awarded the honor.

The following scheme, slightly modified from that of Dr. H. Gadow, will show approximately the present ideas of classification. Phylogenetically we may regard the *Colymbomorpha* and *Pelagomorpha* as branches of one stock, while

the *Electromorphæ* came away independently. The *Coraciimorphæ* have branched off from the last named, the hoactzin and the plaitain-eaters representing one point of alliance. The *Ratitæ*, on the other hand, are a degenerate group probably from the same ancestry as the tinamous.

RATITÆ.

The Ostrich tribe and certain Fossil allies.

CARINATÆ.

Colymbomorphæ:

- I. Sphenisciformes,—Penguins.
- II. Colymbiformes,—Grebes and loons.
- III. Procellariiformes,—Petrels and albatrosses.

Pelagomorphæ:

- I. Cinconiiformes,—1, Cormorants, etc.; 2 herons; 3, storks.
- II. Anseriformes,—1, Palamedea; 2, ducks and geese; 3, flamingos.
- III. Falconiformes,—1, Cathartæ; 2, hawks, etc.

Electromorphæ:

- I. Tinamiformes,—Tinamous.
- II. Galliformes,—1, Hemipods; 2, gallinæ; 3, hoactzin; 4, sand grouse; 5, pigeons.
- III. Gruiformes,—1, Sun-bitterns; 2, rails; 3, cranes; 4, trumpeters; 5, seriema.
- IV. Charadiiiformes,—1, plovers, etc.; 2, gulls and auks.

Coraciimorphæ:

- I. Cuculiformes,—1, cuckoos, etc.; 2, parrots.
- II. Coraciiformes,—1 Coraciæ; 2, owls; 3, caprimulgi; 4, swifts; 5, colies; 6, trogons; 7, woodpeckers.
- III. Passeriformes,—1, Eurylæmidæ; 2, clamatrices; 3, menuridæ; 4, oscines.

The number of species of birds is enormous and a very large portion of ornithological literature has to do with their description, a work which is still progressing; for though it is probable that nearly all the distinct forms of bird-life have been discovered and described, there is still an abundance of closely allied geographic races to be distinguished. This refinement in separation of species and "varieties" in ornithology early reached a point far in advance of that attained in any other group of vertebrates and the effects of peculiar environment and isolation in the evolution of species was apparently first clearly recognized from the study of birds. In some countries, notably in North America, the birds have been so closely examined over large areas that it is possible to trace the exact effect of peculiar climatic conditions upon color, and parallel examples are furnished by several different types of birds. The recognition of large numbers of closely allied geographic races, while deplored by those who would keep our nomenclature within the limits of convenience, is of the greatest importance in broader scientific research. Not only are valuable data thus obtained for the study of the evolution of species in its relation to geographic, distribution and environment, but by recognizing certain peculiarities, however slight, as characteristic of birds breeding in a certain district, it is possible to identify the same form in its winter quarters or *en route*; and already data are being collected in the United States

which before long will throw much light upon the exact course of the migration. The recognition of these geographic races in ornithological nomenclature resulted in the adoption by many ornithologists, notably Americans, of a trinomial system instead of the binomial system of Linnæus, and geographic forms are now denoted by a "subspecific" name attached to the generic and specific ones, as, for example, *Melospiza melodia fallax*. This very materially alters our old conception of a species, just as the theory of evolution modified the conception of orders and families, and we are now coming to recognize that species and subspecies (they differ only in degree) as we find them to-day are forms differentiated from one another in variable degree, some perfectly distinct, others so slightly as barely to be appreciable. The attempt to denote the degree of variation, by any system of names is bound to express merely individual opinion and this explains much of the constant controversy over nomenclature.

The beauty of birds has appealed to the artistic side of many men and many early ornithologists were artists and regarded the colored plates in their books as of perhaps more importance than the text. As examples of ornithological works of this sort may be mentioned Catesby's 'Natural History of Carolina,' Wilson's 'American Ornithology,' and Bonaparte's supplement to it; the elephant folios of Audubon and the many sumptuous works of John Gould. Of recent years the perfection of photographic apparatus has made possible the photography of living birds in all the functions of life, which has proved of great scientific value. By thus bringing together accurate pictures portraying widely scattered species we have material from which valuable deductions are likely to be made. See ANIMALS, CLASSIFICATION OF; BIRDS.

Bibliography.—General works are Gadow, Brehm's 'Thierreich' (Vögel); Newton, 'Dictionary of Birds'; British Museum, 'Catalogue of Birds'; Coues, 'Key to North American Birds'; and Cassells, the Royal, the Standard and the Cambridge 'Natural Histories,' especially Evans, 'Birds' (1900), in the last named series. Newton's 'Dictionary' (1896) contains an immense bibliography relating to systematic and faunistic ornithology. For the United States the early standard works were the 'Ornithologies' of Audubon, Wilson and Nuttall. The publication by Spencer F. Baird (1859) of the 8th volume of the 'Pacific Railway Reports,' dealing with the birds of the country in accordance with advanced knowledge, started a new epoch in the study. This was stimulated again by the publication, first in 1872, of Elliott Coues' 'Key to North American Birds,' which has since passed through many editions. The most important and latest manual is Robert Ridgway's 'Birds of North and Middle America,' begun in 1901; and the best books for the general history and the identification of North American birds and Chapman's 'Handbook to the Birds of Eastern North America' (New York 1912) and Bailey's 'Handbook to the Birds of Western United States' (Boston 1902).

WITMER STONE,
Academy of Natural Sciences, Philadelphia.

ORNITHOPODA, a group of dinosaurs, now included in the *Orthopoda* (q.v.).

ORNITHORYCHUS. See DUCKBILL.

ORNITHOSAURIA, the pterodactyls. See PTEROSAURIA.

ORNITHOSCELIDA, a group named by Huxley to include certain genera of dinosaurs (*Iguanodon*, *Megalosaurus*, etc.), which "present a large series of modifications intermediate in structure between reptiles and birds," though there is no reason to believe that they are directly ancestral to the birds.

ORNITHOSTOMA, the generic name of a huge pterodactyl from the Cretaceous rocks of Kansas, which is probably identical with *Pteranodon*. See PTERODACTYLS.

OROBANCHACEÆ, the broom-rape family. The general properties of this family of plants are astringency and bitterness. The calyx is equally divided into four or five teeth, persistent, inferior; the corolla hypogynous, irregular, persistent, aestivation imbricated; stamens, four; ovary free, one-celled, with two carpels; style, one; stigma two-lobed, divided transversely to the carpels; fruit capsular. The *Orobanchaceæ* are herbaceous parasites, with scales in place of leaves. They attach themselves to the roots of different plants, and have received the name of broom-rapes from the ravages they are supposed to commit among plants of the broom family. The different species attach themselves to different plants, as the *Orobanche major* to broom and furze, *O. ramosa* to hemp, *O. rubra* to thyme, *O. hederae* to ivy. The central cellular portion of the stems is surrounded by fibro-vascular bundles, which connect themselves with those of the plants to which they attach themselves. They have also tubers and ordinary roots, from which it is supposed they may derive nourishment from the soil. See CANCER-ROOT; BROOM RAPE.

OROBUS. See BITTER VETCH.

OROGRAPHY, a term applied to the study of mountains, their chain, branches, etc. The study includes the method of measuring the heights of mountains by trigonometrical survey. The great difficulty to be encountered in this method of measurement arises from the optical illusion occasioned by the different states of the density of the atmosphere, causing a proportionate change of refraction, which may, however, be corrected by hygrometric observation. In modern times it has been usual to ascertain the heights of mountains by barometrical observation. See BAROMETER; GEOGRAPHY; MOUNTAINS; SURVEYING.

OROHIPPUS. See HORSE, EVOLUTION OF.

OROIDE, or **OREIDE**, an alloy, a substitute for ormolu. There are two formulæ for composing it. In the first the ingredients are copper, 100.0; tin, 17.0; magnesia, 6.0; sal-ammoniac, 3.6; quicklime, 1.80; argol or unrefined tartar, 9.0. In the second, less brilliant than the former, zinc is substituted for the tin. The metals are first melted; the other ingredients, after being thoroughly incorporated together by powdering and mixing, are slowly added; and the whole is kept in a state of fusion for about an hour, and the scum removed from time to time.

ORONHYATEKHA, "burning sky," Mohawk Indian: b. on the reservation of the Six Nations, Brantford, Ontario, Canada, 1841; d. Augusta, Ga., 4 March 1907. He attended Toronto University, Canada, and while there organized one of the first "Wild West" shows in which he and some of his Indian friends played the leading parts. With this he made frequent trips about the neighboring towns and thus earned money enough to pay his college expenses. This show made the Indian boy a well-known figure in Canada and along the bordering American States. On the occasion of the visit of the Prince of Wales to Canada in 1860, Oronhyatekha was elected by the Six Nations Indians to deliver, in their name, an address of welcome to the future king, Edward VII. The latter was so impressed with the vivacity, intelligence and oratorical powers of the young Indian that he invited him to England to continue his studies in Oxford. The offer was accepted and Oronhyatekha entered the famous English centre of learning under the protection of Sir Henry Ocland, though it was generally understood in Canada that his expenses were being paid by Queen Victoria. Oronhyatekha was graduated in medicine from Oxford. On his return to Toronto he married a granddaughter of the famous Mohawk chief, Brant. He became a well-known figure in medical circles and secret society lodges. In 1902, at Chicago, he was elected president of the National Fraternal Congress. With the secret societies of his ancestors in mind, he evolved the idea of the Independent Order of Foresters, which he founded in 1881 and of which he remained Grand Ranger until his death. In behalf of this organization he traveled extensively throughout the United States and Canada, where he had the reputation of being a very forceful and ready speaker in both English and Mohawk. He was the most prominent among the speakers at the Indian centennial held at Tyendinaga, Canada, 4 Sept. 1884. He was a student of things Indian and has left a valuable treatise on the Mohawk language.

ORONO, ô-rô-nô, Maine, town, Penobscot County, on the Penobscot River and the Maine Central Railroad, seven miles northeast of Bangor. It was settled in 1774, and became a town in 1806. Its chief industry is the manufacture of lumber, and it contains a number of lumber mills, also pulp and paper mills. It is the seat of the University of Maine, including the agricultural college and the experiment station. Pop. 3,133.

ORONTES, ô-rôn'têz, the classic name for the modern AASI, or Nahr-el-Asi, a river rising on the east of the Anti-Libanus, in a natural basin of rock, the site being marked by an ancient monument. It flows north through the plain of Hamah to the Lake of Antioch, and thence southwest into the Mediterranean. Its entire course is about 200 miles, though its valley was, for many centuries, the highway to and from Egypt.

OROPUS, ô-rô-pūs, town of Attica, in ancient Greece, situated on the frontier of Boeotia and celebrated as the site of the temple of Amphiarus. It was a famed place of pilgrimage in the ancient world. Consult Dürnbach, 'De

Oropo et Amphiarai Sacro' (Paris 1890) and Frazer, J. G., 'Pausanias' (Vol. II, London 1898; 1913).

OROSIUS, ò-rō'sī-ūs, **Paulus**, Spanish historian and theologian: b. Tarragona, Spain, about 390 A.D. He became a Christian presbyter, resided a considerable time with Saint Augustine at Hippo and wrote, at his suggestion, a general history of the world, 'Adversus Paganos Historiarum Libri VII,' to prove that the Christians were not to blame for the downfall of the Roman Empire as the heathen alleged. He tries to picture the wretchedness and evils of the heathen period in as dark colors as possible, making use of the works of Livy, Tacitus, Suetonius, and other Roman writers. His history, however, is regarded by scholars as being of little value, though it long enjoyed a great popularity, and was translated into Anglo-Saxon by Alfred the Great with modifications and additions. Orosius is also said to have written a work on the errors of Priscillian and Origen, and still other writings are attributed to him. His history has been edited by Zangemeister (1882), and several English translations and editions of Alfred's translation have been published. Consult Mörner, T. de, 'De Orosii Vita' (Berlin 1844).

OROTAVA, ò-rō-tā'vā, Canary Islands, a town in the northwest of the island of Tenerife, formerly the capital and court of the principal kingdom of the Guanches. It is regularly built, and among its buildings are a beautiful church with three naves, and an English church. In a valley east of the town is a botanic garden. Orotava is a summer resort much frequented by European health seekers. It has an export trade in wine and cochineal. Pop. about 12,000.

O'ROURKE, Edmund. See FALCONER, EDMUND.

OROVILLE, Cal., city and county-seat of Butte County, on the Southern Pacific, the Western Pacific, and the Northern Electric railroads, 75 miles north of Sacramento. It is located in a region with large fruit-growing, stock-raising and other agricultural interests and nearby are Feather River Canyon and the Falls of Fall River. The city has a Carnegie library, fruit and olive packing and curing stations, railroad repair shops, etc. Pop. 3,340.

OROZCO Y BERRA, ò-rōs'kō ē bër'rā, **Manuel**, Mexican historian: b. City of Mexico, 8 June 1816; d. there, 27 Jan. 1881. He studied both law and engineering and became editor of *El Porvenir* in 1846. He held numerous positions of trust under the government, was professor in the National Military School and became judge of the Supreme Court of the nation in 1863. In 1852 was appointed director of archives, and later he was director of the National Museum and Councillor of State during the régime of Maximilian. After the return of Juárez to power, Orozco was imprisoned for a while. On his liberation he devoted his time to archaeology and kindred studies. Orozco had a very logical and scientific mind; and no name stands higher as a scientist than his in Mexico. His vast scientific work is a mine of wealth in all that relates to ancient Mexico. He was the first great "Americanista" in his own land and since his day none of his countrymen have surpassed him in Indiology and profound knowledge of ancient Mexico. Among his published

works are 'Geografía de las lenguas y carta etnográfica de México' (1864), and 'Historia de México,' his most famous work (1880-81).

OROZCO Y JIMENEZ, Francisco, Mexican bishop and historian: b. Zamora, Mexico, 19 Nov. 1864. He was educated at the College of Jacona, Mexico, the South American College and Gregorian University, Rome, and in 1887 was ordained to the priesthood. He was successively professor of Latin at Zamora Seminary, professor of philosophy, theology, Scripture, liturgy and Hebrew in the University of Mexico, chaplain of Saint Francis' and vicerector of the School of Arts, Zamora, and vicerector of the Seminary at Mexico City. From 1902-12, Dr. Orozco y Jimenez was bishop of Chiapas and in the latter year was transferred to the see of Guadalajara. In January 1917 the Carranza government ordered his deportation. He established the first electric plant and erected a public monument to Las Casas at S. Cristobal Las Casas, Mexico. The bishop was president of the labor section at the Catholic Congress of Oaxaca. He has published 'Colección de documentos para la historia de Chiapas,' and numerous contributions to the religious press.

ORPHANS' COURT, in Pennsylvania and a few other States, where it occupies a position similar to that of the surrogate; devoted largely to probate matters, such as the granting of letters of administration; to take proof of wills and to direct and control estates and the settlement of accounts of executors and administrators. See also COURT.

ORPHEUS, òr'fūs, in Greek mythology, an important personage, surrounded by a multitude of legends, which invariably associate him with Apollo and the Muses. To him is attributed the application of music to the worship of the gods. Apollo presented him with his lyre, and the Muses instructed him to use it, so that he moved not the beasts only, but the woods and rocks with its melody. Having lost his wife, Eurydice, by the bite of a serpent he descended to Hades to try and get her back. His music so moved the infernal deities, Pluto and Proserpine, that they consented to her return to earth, only her husband, whom she was to follow, must not look back till they had reached the upper world. This condition the impatient Orpheus violated and lost his wife forever. He is said to have met his death at the hands of a band of furious women engaged in the mystic rites of Bacchus. He is represented as one of the Argonauts, and to him is ascribed the origin of the so-called Orphic mysteries connected with the worship of Bacchus. The bulk of the poems attributed to Orpheus in modern times have been proved to be forgeries of Christian grammarians of the Alexandrian school. A portion of them, however, belong to the time of Onomacritus, or earlier, and include hymns, a theogony, a poem called 'Minyas, or the Descent Into Hades'; oracles and songs for initiation, and sacred legends. Among those who have investigated the Orphic writings are Ottfried Müller, Grote and Lobeck. See also APOLLO; BACCHUS; EURYDICE; MUSES.

ORPHEUS C. KERR, the pseudonym of ROBERT HENRY NEWELL (q.v.).

ORPIMENT, the native mineral, yellow sulphide of arsenic, As_2S_3 . It forms rhombic trimetric prisms of translucent lemon-yellow color. Its specific gravity is 3.45, and its hardness 1.5-2. It is very poisonous. It was formerly used as a pigment and was known as king's yellow.

ORPINE, or **LIVE-FOREVER**, a perennial herb (*Sedum telephium*) of the family *Crassulaceæ*. It is a native of Europe and northern Asia, whence it has been introduced in cool climates throughout the civilized world. Though it produces few blossoms it spreads rapidly by means of its roots. Thrifty specimens attain heights of 15 to 18 inches, bear obtuse, oval, toothed, fleshy leaves, and pink or sometimes white flowers in dense rounded cymes, both terminal and lateral. Several horticultural varieties are used in rock-gardens and places where little attention is required.

ORR, *ôr*, **Hugh**, American inventor: b. Lochwinnoch, Renfrewshire, Scotland, 13 Jan. 1717; d. Bridgewater, Mass., 6 Dec. 1798. He came to America in 1737 and settled at Bridgewater, where he began work as a gunsmith and manufactured edged tools. In 1753 he invented a machine for dressing flax, and his other inventions were many. He was an ardent patriot in the Revolutionary War, and erected a foundry, where he cast cannon and shot for the army. After the war he became a member of the Massachusetts senate.

ORR, **James**, Scottish theologian: b. Glasgow, 11 April 1844; d. 6 Sept. 1913. He was educated at Glasgow University and the Theological Hall of the United Presbyterian Church. He entered the ministry and was pastor of East Bank Church, Hawick, 1874-91; in 1895 lectured in Chicago on German theology, and in 1897 lectured on the Elliot and Morgan foundations at Allegheny, Pa., and Auburn, N. Y. He was professor of church history in the United Presbyterian Theological College, Scotland, 1891-1901 and from 1901 until his death was professor of apologetics and theology in the Glasgow College of the United Free Church. He took a prominent part in the union of the United Presbyterian and Free churches. He published 'The Pulpit Commentary' (1891); 'The Christian View of God and the World' (1893); 'The Supernatural in Christianity' (1894); 'Early Church History and Literature' (1901); 'The Progress of Dogma' (1902); 'David Hume' (1903); 'The Image of God' (1905); 'Problems of the Old Testament considered in Relation to Recent Criticism' (1906); 'The Resurrection of Jesus' (1908); 'Sidelights of Christian Doctrine' (1909); 'History and Literature of the Early Church' (1913).

ORR, **James Lawrence**, American legislator: b. Claytonville, S. C., 12 May 1822; d. Saint Petersburg, Russia, 5 May 1873. He was graduated from the University of Virginia in 1842, admitted to the bar in 1843 and established a law practice in Anderson, S. C., also editing the *Anderson Gazette*. He was elected to the State legislature in 1844, served two terms, and in 1848-59 was a member of Congress, officiating as speaker of the House in the 35th Congress. A strong opponent of secession, he opposed it as long as possible, and then followed the lead of his native State. He commanded one of the first Confederate regiments

raised in South Carolina, but in 1862 entered the Confederate Senate, of which he was a member until the close of the war. He was the first governor of South Carolina after the restoration of her rights as a State of the Union, serving from 1866-68, and in 1872 was appointed Minister to Russia, where he died in the following year.

ORRENTE, *ôr-rân'tā*, **Pedro**, Spanish painter: b. Monteleagre, Murcia, about 1560; d. 1644. It is supposed that most of his instruction was had from El Greco, whose friend he was. He devoted himself to Scriptural themes, working at Toledo, Valencia, Cuenca, Madrid, Seville and elsewhere. Orrente belongs to the naturalistic school. His best-known works are 'Departure of the Israelites,' in the Madrid Academy; 'Miracle of Saint Ildefonso,' in Toledo Cathedral; 'John the Baptist,' now in Vienna; and 'The Adoration of the Magi,' in the Prado, Madrid.

ORRERY, *ôr'ê-rî*, **Earls of**. See **BOYLE**.

ORRERY, in astronomy, a machine for representing the motions of the planetary bodies. Distinct names have been given to various modifications of it: the planetarium, which exhibits the orbital paths of the planets and their satellites; the tellurium, which shows the motions of the earth causing day and night, the seasons, and the variable length of the former as dependent upon the latter; the lunarium, which shows the motions of the moon; and the satellite machine, chiefly intended to represent the motions of Jupiter and his satellites. The ordinary orrery was invented by George Graham about 1700, and first patronized by the Earl of Orrery. Steele, probably supposing the earl to be the first promoter if not the inventor of it, called it by his name. The contrivance is useful rather in aiding the conceptions than in elucidating truths; but it is mischievously faulty owing to the impracticability of representing in model anything like the proportions subsisting among the planetary bodies.

ORRIS ROOT, the rhizome or underground stem of a white-flowered species of iris, *I. florentina*, a native of the south of Europe. In a dried state it is well known on account of its communicating a grateful odor, resembling that of violets. It was formerly much employed in medicine, but is now little valued except as a perfume. It is exported from the Mediterranean in considerable quantities, and, among other uses, is employed in the manufacture of tooth powder. See **IRIS**.

ORRVILLE, Ohio, village of Wayne County, on the Pittsburgh, Fort Wayne and Chicago, the Cleveland, Akron and Cincinnati and the Wheeling and Lake Erie railroads, 15 miles south of Akron. It contains a wood-preserving factory, mattress works and drill factory. It enjoys local fame as a horse mart. The village owns the water-supply system and the electric-lighting plant. Pop. 4,107.

ORSI, *ôr'sê*, **Achille d'**, Italian sculptor: b. Naples, 1845. He received his training at the Royal Institute of Naples and afterward at Rome. He first attracted general attention by his remarkable work 'The Parasites' at the Naples Exposition of 1877. His 'Proximus Tuus' followed in the same satiric vein against the smug bourgeoisie. It is now in the National

Gallery, Rome. There is a statue of Alphonso of Aragon by him at Naples; other works are 'Boy Carrying Water Jars' and 'A Sailor's Head,' perhaps his greatest works.

ORSINI, ōr-sē'nē, Italian noble family dating back to the 8th century. Popes Paul I (757) and Eugene II (824-827) were of this name. In the 11th century the Piedmont branch were prominent among the members of the Guelph party, even opposing Frederick Barbarossa. But the Roman branch is better known, especially for its rivalry with the Colonna family, beginning at the close of the 13th century and standing for the Church as against its rival for the people. The first great name in this branch is Nicholas III, who was Pope from 1277 to 1280. Even in the city of Rome the Orsini built strong fortresses, thanks to the connivance of Eugene IV, one of them covering the site of the Marcellus Theatre. They boldly opposed the attempt of Henry IV to assert his power in Rome, and the most notable part of their struggle with the Ghibelline Colonnas was the mad and unrestrained fighting of 1333-35, which by its abuses paved the way for the brief Roman republic under Cola da Rienzi. The important members of the next centuries were: **VIRGINIO**: d. 18 Jan. 1497, a famous condottiere, who fought for the Pope, then for the king of Naples and finally for Charles VIII; **NICCOLO**, count of Petigliano: b. 1442; d. 1510; head of the Angevin party, and later leader of the Venetians against the League of Cambrai; **VINCENZO MARIA**, who became Pope Benedict XIII in 1724; and **FULVIO ORSINI** (1529-1600), an antiquarian and author of 'Familiae Romanae' (1577).

ORSINI, Felice, fā-lē'chā, Italian revolutionist: b. Meldola, December 1819; d. Paris, 13 March 1858. He studied at Imola and Boulogne, took part in several plots against the pontifical government, was condemned to the galleys for life at 25, was pardoned by Pius IX, became a leader of the rising of 1848 and after the fall of the republic engaged in several unsuccessful plots. He was arrested and imprisoned in 1854, escaped to England, where he made a living as a lecturer on the papacy. Hoping that the death of Napoleon III would be followed by a general Italian rising, he made his way to Paris in December 1857, and 14 Jan. 1858, with his two accomplices, threw three bombs at the emperor and empress in the Opéra. Many were killed by the explosions, but Napoleon and Eugenie were unhurt. Orsini was executed with one of his accomplices, the other being pardoned at the empress' request. He was the author of 'Austrian Dungeons in Italy' (1857) and 'Memoirs and Adventures' (1857).

ORSOVA, ōr'shō-vō, Rumania, a frontier town on both banks of the Cerna at its confluence with the Danube, near the Vaskapu or Iron Gates, 92 miles east of Belgrade. **OLD ORSOVA**, the Roman Tierna, on the west bank of the Cerna, has a modern harbor, is a station for the Danube steamers and an important railway junction. Pop. about 4,610. **NEW ORSOVA** (pop. about 3,500), on the opposite bank, was a fortified town held by Austria 1878-1918, who also were masters of it between 1716 and 1738; the Turks held it both before 1716 and after 1738. In 1890-96 a costly canal and other

works were made in order to facilitate navigation at the rocky bend called the Iron Gates.

ÖRSTED, ər'stēd, **Hans Christian**, Danish physicist: b. Rudkjøbing, on the island of Langeland, 14 Aug. 1777; d. Copenhagen, 9 March 1851. He studied from 1794 at Copenhagen University, became (1800) adjunct professor of the medical faculty and started lectures on chemistry. After traveling (1801-03) through Holland, Germany and spending a year in Paris, he was appointed (1806) professor of physics at the Copenhagen University. He was the discoverer of electro-magnetism, as shown in 'Experimenta circa effectum conflictus electrici in acum magneticam' (Copenhagen 1820). In 1824 he founded a society for propagating the science of natural philosophy and became (1829) director of the Copenhagen Polytechnical School. He wrote 'Ideen zu einer neuen Architectonik der Naturmetaphysik' (Berlin 1802); 'Ansicht der chemischen Naturgesetze' (ib. 1812); 'Tentamen nomenclaturæ chemicæ omnibus linguis scandinavogermanicis communis' (Copenhagen 1814); 'Naturlärens mekaniske Deel' (ib. 1844; 3d ed., 1859); 'Aanden i Naturen' (Copenhagen 1849-50); 'To Capittler af det Skjønnes Natur' (Copenhagen 1845). A collective issue, in nine volumes, of his works was published under the title 'Samlede Skrifter' (Copenhagen 1850-51). A bronze statue was erected in Copenhagen in 1876 in honor of the discoverer of electro-magnetism, one of the most revolutionary scientific discoveries of modern days, and the Copley Medal was awarded him by the Royal Society of England. Consult Hauch and Forschhammer, 'Örsteds Leben' (Spanndau 1853); Beaumont, Elie de, 'Mémorial de Örsted,' Alexander's translation in Smithsonian Institution, Annual Report, 1868 (Washington 1869).

ORTEGA, Juan de, Spanish monk and writer; credited with the authorship of 'Lazarillo de Tormes,' the first of the picaresque or vogue novels, which set the vogue for this type of fiction. The work appeared anonymously but in 1605 José de Ligüenza, a Hieronymite monk, attributed the work to Fray Juan de Ortega. In 1607 Vátere André, and in 1608 André Schott, named Diego Hurtado de Mendoza as the author, and it was not until 1880 that Morel-Fatio discredited the latter statement as untenable. (See LAZARILLO DE TORMES). Consult Morel-Fatio, A., 'Études sur Espagne' (Paris 1888; 2d ed., 1895); Markham, (Sir) C., 'Life of Lazarillo de Tormes' (London 1908).

ORTEGAL, ōr'tē-gāl (Sp. ō-tā-gāl'), Cape. See CAPE ORTEGAL.

ORTELIUS, ORTEL, or OERTEL, ər'tēl, **Abraham**, Flemish geographer: b. Antwerp, 4 April 1527; d. there, January 1598. He was wealthy, traveled in England, France, Germany, Italy and had a wide acquaintance with the geographers of his time. In 1570 he published his 'Theatrum Orbis Terrarum,' a collection of maps with short descriptions of the various countries in Latin. This was long a standard geographical authority in Europe, and there are various editions in Latin, French and German. Several of the maps are of great interest for the early cartography of America.

Ortelius published other geographical works, such as 'Synonymia Geographica' (1578) and 'Itinerarium per Nonnullas Galliae Belgicae Partes' (1584). He amassed a museum of coins, antiquities, etc. He was appointed royal geographer by Philip II in 1575.

ORTH, *ôrth*, **Bertrand**, Canadian Roman Catholic prelate: b. Algert, Rhine Province, Prussia, 5 Dec. 1848. He received a theological education at the American College in Louvain, Belgium, and was ordained in 1872, when he was sent to Oregon as missionary to the Indians. He remained in that position until 1890, when he was appointed United States post chaplain at Camp Harney. In addition to his missionary work he had edited the *Catholic Sentinel* of Portland and taught in various Catholic colleges. In 1900 he was consecrated first bishop of Victoria, Vancouver Island; in 1903 was elevated to the archbishopric and resigned in 1908.

ORTH, **Godlove Stoner**, American legislator: b. near Lebanon, Pa., 22 April 1817; d. Lafayette, Ind., 16 Dec. 1882. He was graduated from the Pennsylvania College at Gettysburg, admitted to the bar in 1839 and began his law practice in Lafayette, Ind., where he at once interested himself in politics. In 1843-50 he was a member of the State senate, and in 1861 was appointed one of the five commissioners to consider the possibilities of a peaceful solution of the impending troubles. His sympathies were on the Union side, and after a brief term of military service he was elected to Congress and gave support to the policy of Lincoln. He was in the 39th, 40th, 41st, 43d, 46th and 47th Congresses. In 1875 was appointed Minister to Vienna.

ORTHIS, a large genus of palæozoic brachiopods (q.v.), typical of the strophomenaceous family *Orthidæ*, which lived in such abundance and variety from the Ordovician to the Carboniferous periods that they are known from all over the world and the Ordovician and Silurian formations alone have yielded no less than 400 species. American specialists, it should be said, subdivide the genus into a dozen or more subgenera. The orthids have a shell, squarish in outline, with the surface covered with radiating striæ or costæ; the valves more or less convex; the small or dorsal valves, sometimes nearly flat or slightly concave. A distinguishing feature of the genus is that the well-developed hinged area is usually divided by a large, open delthyrium. A deltidium is developed only in younger growth stages. Consult Woods, H., 'Palæontology' (4th ed., Cambridge 1909); Zittel-Eastman, 'Text-book of Palæontology' (1900).

ORTHITE, natural hydrated silicate of aluminum, iron, calcium and cerium, with long, straight prismatic crystals (hence its name), which occur in feldspar. Its formula is $H_2(CaFe)_4(AlC)_6Si_6O_{26}$. Its specific gravity is between 3.37 and 3.8, its hardness between 5 and 6. Orthite occurs in granite, gneiss, syenite and other rocks; usually is of a brownish or yellowish color and contains small quantities of many rare elements, such as lanthanum, yttrium and didymium. It is found in the Urals and in Sweden, Norway, Greenland and the Atlantic States.

ORTHOCERAS, *ôr-thôs'ê-ras*, a genus of fossil cephalopods, allied to the nautilus, having straight, tapering, smooth-chambered shells, with the siphuncle central, which occur from the Silurian to the Trias. It forms the type of a family *Orthoceratidæ*, some of the species of which must have been more than six feet long and one foot wide. Related groups had shells curved in various degrees, thus approaching the coiled nautilus form.

ORTHOCLASE, a variety of monoclinic feldspar, called common or potash feldspar, owing its scientific name to the rectangular cleavage of its crystals; it is a silicate of aluminum and potassium, with the general formula $K_2AlSi_6O_{18}$; and occasionally has some sodium in place of the potassium. The percentage of silica is usually 65 and of potash about 12. The color is white or green, sometimes rose or yellowish; its specific gravity is 2.53 to 2.59, and its hardness 6. It may be transparent or opaque. It is an essential component of many stones, such as granite, syenite, porphyry, trachyte and gneiss. It is found in larger masses enclosed in granite and other igneous or metamorphic rocks. It is unaffected by acids, save hydrofluoric; but is decomposed by water containing carbonic acid, the alkali being removed and clays being formed.

ORTHOGRAPHY, in *architecture*, the geometrical scheme of an elevation of a building or section thereof; in *music*, the art of recording effects and tones by the proper conventional characters; in general, the art of setting down words correctly as regards their component letters according to accepted usage. See **PHONETICS**; **SPELLING**; **SPELLING REFORM**.

ORTHOPÆDICS (Greek, *ὀρθός*, straight, + *παῖς*, child), a branch of medical science relating to the cure of natural deformities; not, as the name implies, restricted to children, although childhood is usually favorable to treatment. The practice of orthopædics includes prophylactic or preventive treatment and curative treatment. The object of the first is to prevent deformities in children who, from the delicacy of their constitution, are exposed to them. Its means are hygienic; and its aim is to aid by natural means the symmetrical development of the body. Among these means one of the most important is pure air. Children have been known to recover from an incipient deformity of the spine or members merely by being sent to the country. The compressed-air bath has been used with success as an auxiliary in this branch of treatment. Muscular exercise methodically applied is another resource of great importance. It has the advantage not only of developing the muscles, but of aiding digestion and secretion. Treatment by curative orthopædics has been applied with success to a great variety of malformations both of spine and members. The manufacture of apparatus for the mechanical treatment of deformities has become a distinct branch of business, and there are in various countries numerous institutions where such treatment is systematically given. The paralysis incident to an attack of poliomyelitis, or infantile paralysis, yields to protracted treatment of the affected parts, by electric stimulation, manual treatment, exercise, etc.

ORTHOPHOSPHORIC ACID. See PHOSPHORIC ACID.

ORTHOPODA, an order of herbivorous dinosaurs (q.v.), in the classification of Gadow, which includes as subordinate groups the plantigrade *Stegosauri* and the digitigrade *Ornithopoda* of Marsh. The group-characters are anatomical, especially those of the pelvis, which are very bird-like, and of the jaws, the premaxilla having no teeth. Consult Gadow, 'Amphibia and Reptiles' (1901).

ORTHOPTERA, or straight-winged insects, one of the Linnæan orders of *Hexapoda*, which has undergone least change in the hands of modern systematists. The three regions of the body are distinct; the head is large with strong, biting jaws, and long or short filiform antennæ; the prothorax is usually greatly developed, and may form a shield partly covering the mesothorax; and the abdomen is usually full and terminated by a pair of claspers in the male and a more or less prominent ovipositor in the female. The anterior pair of wings are of little use in flight, but they are thickened and serve as covers to protect the broad, membranous, netted-veined hind wings, which, when not in use, are folded longitudinally like fans and concealed beneath the covers. In some genera wings are absent. Being of terrestrial habits and seldom flying far, the legs are well developed for running, leaping, or, as in the mole-cricket, for burrowing. There is a gradual change without any sudden metamorphosis from the larva to the imago, the pupa being active and differing from the adult only in the undeveloped wings and reproductive organs; nor do the larvæ differ greatly in appearance. The eggs are usually laid on the ground and sometimes, as with the grasshoppers, in nests or cells. With the striking exception of the mantids, almost all of the species are strictly herbivorous and among them are some of the most serious pests with which the husbandman has to contend. One characteristic of this group is the presence of sound-producing structures, by means of which, in some families by rubbing, in others by concussion, or by a combination of both methods, are produced the noises familiar to use as the "chirping" of crickets, the "calling" of katydids, "whirring" of grasshopper (qq.v.), etc. Examples of how much sounds are made are furnished by the locusts and grasshoppers, which produce sounds in several ways. The *Acrididæ* rub the inner surface of the hind Femora, upon which there is a row of minute spines, against the outer surface of the fore wing. In this case each fore wing serves as a fiddle and each hind leg as a fiddle-bow. The *Locustidæ* and *Gryllidæ* rub together the upper surface of the front edge of the hind wings and the under surface of the fore wings. This is done while the locust is flying, and the result is a crackling sound. The *Acrididæ* have auditory organs on the sides of their abdomens, while the "ears" of the *Locustidæ* and *Gryllidæ* are on the front legs. This consists of a peculiar arrangement of the veins and cells of a portion of each fore wing near its base. This arrangement differs in the different species, but in each it is such that by rubbing the fore wings together they are made to vibrate, and thus produce the sound. The principal families are the *Forficulidæ* or

earwigs, the blind *Hemimeridæ*, the *Blattidæ*, or roaches, the *Phasmidæ*, or walking-sticks, the *Mantidæ*, or praying insects, the *Gryllidæ*, or crickets and mole-crickets, the *Locustidæ*, or green grasshoppers, and the *Acrididæ*, or locusts, all of which are elsewhere described. Consult the 'Text-books' of Comstock, Packard, Carpenter and others; and Howard, 'The Insect-book' (1901), which contains an extensive bibliography of the group.

ORTLER-SPITZE, ört'lër-spit'sè, or **ORTLER**, Italy, a mountain in the Tyrol, on the borders of the Engadin, 70 miles southwest of Innsbruck. It is about 12,802 feet high, and the loftiest peak in the Tyrol. The summit commanding one of the most extensive views in the Rhetian Alps was long considered inaccessible and was first ascended in 1804.

ORTMANN, Arnold Edward, American Palæontologist: b. Magdeburg, Prussia, 8 April 1863. He studied at the universities of Jena, Kiel and Strassburg, gaining the Ph.D. diploma at Jena in 1885. After doing military service in Germany he was sent to Zanzibar, Africa (1890-91), in search of natural history specimens. He came to the United States in 1894, was made curator of invertebrate palæontology (1894-1903) at Princeton, and became (1903-) curator of invertebrate zoology at Carnegie Museum, Pittsburgh. He was professor of physical geography at the University of Pittsburgh from 1910. In 1911 he was given the degree Sc.D. by the University of Pittsburgh. He was a member of the Princeton Arctic Expedition in 1899. He has written among numerous other works 'Grundzüge der Marinen Tiergeographie' (1886); 'Continuation of Die Decapodon in Bronn's Klassen und Ordnungen des Tierreichs' (1898-1900); 'Tertiary Invertebrates of the Princeton Expedition to Patagonia' (1902). Besides being associate editor of the *American Naturalist* he has written many articles for the periodicals.

ORTOLAN, a European yellowish-brown bunting (*Emberiza hortulana*) famous as a dainty. It is migratory, spreading over northern Europe in summer to breed, and making its nest in bushes or small trees, and singing pleasantly. Toward autumn, when it begins to migrate southward, it is plump and regarded as excellent eating. These birds are caught in great numbers at that season along the shores of Italy and the eastern Mediterranean, and are kept in confinement and fed for some time until they become exceedingly fat and delicate, and form a table luxury. The favorite method of preparing the ortolans for table consists in roasting them in egg shells—a mode of cookery borrowed from the ancients, among whom these birds brought very high prices. In former times the island of Cyprus formed a chief depot for the exportation of these birds, which were pickled in spices and vinegar and packed in casks containing from 300 to 400 each. From 400 to 500 casks are annually exported from Cyprus.

ORTON, òr'tón, Edward, American educator and geologist: b. Deposit, N. Y., 9 March 1829; d. Columbus, Ohio, 16 Oct. 1899. He was graduated from Hamilton College in 1848, and later studied at Andover and at Harvard and entered the ministry. In 1856 he took the chair

of natural science at the Albany State Normal School, from 1859 to 1865 he was principal of the preparatory academy of Chester, Orange County, N. Y., accepting in the latter year the chair of natural science at Antioch College, Yellow Springs, Ohio, where in 1872 he was elected president. In 1873 he was called to the presidency of the newly-founded Ohio State Agricultural and Mechanical College, which has since become the Ohio State University. His university work was of great value, as he was a natural teacher and organizer in addition to his scholastic attainments. He was assistant on the geological survey of Ohio in 1869-77, and in 1882 was appointed State geologist, which position he filled until his death, and he frequently served on, and wrote sections of the reports for, the United States geological surveys. He resigned his presidency of the college in 1881, but continued to fill the chair of geology during his life. In 1896 he was president of the Geological Society of America. Among his works are 'Economic Geology of Ohio' (1883-88); 'Petroleum and Inflammable Gas' (1887), etc.

ORTON, Edward, Jr., American industrial chemist: b. Chester, N. Y., 8 Oct. 1863. He received (1884) the degree E.M. at Ohio State University and became (1884-88) chemist and superintendent of blast furnaces. The regular manufacture of high silicon alloy of iron, "ferro-silicon," in the United States was introduced first by him, at the Bessie Furnace, New Straitsville, Ohio, 1887-88. In the latter year he entered the ceramic industries of Ohio, managing several plants till 1893. He was the first to start the agitation (1893) that brought into being (1894) the first United States school for teaching the technology of the clay, glass and cement industries and he was director till 1916. From 1902-06 and from 1910-16 he was dean of the College of Engineering of Ohio State University, and from 1899-1906 he was State geologist of Ohio. He has written 'Clays of Ohio and the Industries Established Upon Them' in *Ohio Geological Survey*, Vol. V (1884); 'The Progress of the Ceramic Industry' (1903), besides a number of technical articles and reports published in the periodicals.

ORTON, James, American Congregational clergyman, naturalist and traveler: b. Seneca Falls, N. Y., 21 April 1830; d. on Lake Titicaca, Peru, 25 Sept. 1877. He was graduated from Williams College in 1855, pursued theological studies at Andover and entered the ministry in 1860. He was professor of natural science in Rochester University in 1866, and the next year conducted an exploring party of students across South America, on the geology and physical history of which he was an authority. He was professor of natural history in Vassar College 1869-73, and at the time of his death was attached to an exploring expedition in Peru. His works include 'The Andes and the Amazon' (1870); 'Underground Treasures' (1872); 'Liberal Education of Women' (1873); 'Comparative Zoology' (1875).

ORTYGAN. See **BUTTON-QUAIL**.

ORURO, ô-roo-rô, Bolivia, a department lying in the western part, bounded on the west by Chile, on the south by the department of Potosi and on the north by the department of La Paz; area, 21,350 square miles. It is the

smallest of the departments of Bolivia. The Andes Mountains follow the western boundary, and the Cordillera Real the eastern; the department lies in the Titicaca Basin. The surface is mostly an elevated plateau, rarely sinking below the level of 12,000 feet; the salt lake of Allugas is situated in the eastern part. There are numerous marshes and saline plains, the soil in general is unfitted for agriculture and the climate is cold. There is considerable mineral wealth, particularly in tin, silver and copper, and mining is the chief and most profitable industry; cattle are also raised in some sections. Pop. about 145,000, of which a considerable portion are Indians.

ORURO, Bolivia, city, capital of the department of Oruro, within four miles to the east of the Desaguadero River, 125 miles southeast of La Paz. It is on a plain over 12,000 feet above sea-level, about 10 miles north of Lake Allugas. It was founded in 1590, and during the 17th century was very prosperous, owing to the mines in the vicinity, having at that time over 70,000 inhabitants. Later the mines were abandoned, the population declined rapidly and a portion of the city fell into ruins. During the last decade of the 19th century, a railroad connecting it with Antofagasta, Chile, has been the means of reviving its prosperity to a certain extent. Tin is mined in the vicinity, and considerable quantities of tin, as well as copper and silver, are exported. Pop. 25,000.

ORVIETO, ôr-vê-â-tô, Italy, a city and episcopal see in the province of Perugia, Umbria, 78 miles by rail northwest of Rome. It is built on an isolated tufa rock, 1,327 feet above sea-level, and 765 feet above the junction of the Paglia and Chiana, is surrounded by mediæval walls and is reached from the railroad depot by a funicular or inclined railway. The cruciform cathedral (1290-1580), one of the most beautiful and richly adorned specimens of Italian Gothic, is built of black and white marble, and measures 295 feet by 109. The façade is unsurpassed in richness of material and in the beauty of its mosaics, sculptures and elaborate ornamentation. The interior also is magnificently decorated with sculptures and with paintings by Luca Signorelli, Fra Angelico and other noted Italian artists. Two other churches of the 11th century, the bishop's palace, the Jesuit College, Saint Patrick's Well (1527-40), with its 250 steps, and the palaces Petrucci and Gualtieri deserve special notice, the former for its fine collection of paintings and the latter for its cartoons by Domenichino, Annibale Caracci and other eminent masters. Orvieto, called in the 7th century A.D. Urbs Vetus, of which its present name is a corruption, is supposed to occupy the site of the Etruscan Volsinii. It was created an episcopal see in 509 A.D., and in the Middle Ages it gave shelter to 32 popes; the papal palace, converted into a municipal museum in 1898, has numerous interesting local antiquities, including the contents of an Etruscan necropolis discovered on the east side of the town in 1874. The chief trade of the city is in cattle, grain, wine, oil and silk. Pop. with suburbs about 20,000.

ORYX, ô'riks, a genus of antelopes represented by the addax, Beatrix antelope, beisa and other species, found chiefly in northern Africa.

The gemsbok of southern and central Africa is another ally. These antelopes are of comparatively large size. The horns are very long, curved and ringed. These form powerful and effective weapons for defense, and a wounded oryx is a dangerous animal for a man to approach. Their desert habitat is indicated by the prevalent reddish-white uniform tint of their coats, almost the only distinguishing color-marks being upon the face. These antelopes are now greatly reduced in numbers, and some of the northern species are nearly extinct. One or another species is often depicted upon the monuments and mural paintings of ancient Egypt, most frequently, probably, the beisa (q.v.). The species most generally known as the oryx is *O. leucoryx*.

OS, Gregorius Jacobus Johannes van, Dutch painter: b. The Hague, 20 Nov. 1782; d. Paris, France, 11 July 1861. After taking a prize at Amsterdam (1809) and being awarded a gold medal at Paris (1812) he accepted employment as a designer and enamel painter at the porcelain manufactory at Sevres. He was eminently successful in the portrayal of flowers, fruit and other still-life, but he also produced several landscapes. He was known among his French admirers as the "Rubens of flower painting." So great was his scientific accuracy in drawing plants that he was engaged to furnish most of the illustrations in the 'Flora Batava.'

OS, Jan van, Dutch painter (father of the preceding): b. Middelharnis, Holland, 1744; d. The Hague, 1808. His studio was at The Hague throughout his artistic career; here he was director of the Académie des Belles Lettres, being a poet as well as a painter of flowers, fruits, landscapes, marines and animals. His flowers are inferior to those of Van Huysum, whom he made his model, but his works are to be found in all important collections, and a picture of his entitled 'Flowers in a Vase, with a Cat on the Table' sold in 1883 for \$1,217.

OS, Pieter Gerardus Van, Dutch painter, son of the preceding: b. The Hague, 1776; d. there, 1839. Although he was trained in art by his father, the flower painter, he made Paul Potter his model, and painted many famous landscapes with cattle in the foreground, and his works were eagerly sought by connoisseurs from all parts of Europe. After serving in the campaign of 1813-14 he produced several battle scenes, some of which are in the Museum at Amsterdam. He was also an excellent etcher.

OSAGE, ō'sāj, Iowa, city and county-seat of Mitchell County, on the Red Cedar River and on the Great Western and the Illinois Central railroads, about 95 miles in direct line northeast of Fort Dodge. It is the commercial and industrial centre of a large productive agricultural region in which there are extensive dairy, nursery and stock-raising industries. It is the seat of the Cedar Valley Seminary, and it has the Sage Public Library. The city owns and operates the waterworks. Pop. 2,878.

OSAGE, a river which has its rise in the prairies of eastern Kansas and enters the State of Missouri at Bates County, flows east and northeast, joins the Missouri River about 10

miles below Jefferson City and has a basin of 15,000 square miles. It is about 495 miles long, and navigable, part of the year, 200 miles from the Missouri. It is a winding stream with many deep curves of nearly parallel sides. It is known in Kansas as the Marias des Cygnes.

OSAGE ORANGE (*Toxylon pomiferum* or *Machura pomifera*), a tree of the order of *Urticaceae*, growing wild in the southwestern parts of the United States. It was first found near a village of the Osage Indians, which fact, connected with the globular form and golden color of its fruit, originated its popular name, but it has no botanical relationship to the true orange. The Osage orange, also called "bow-wood" (by French-American writers bois d'arc) and "yellowwood," is a striking and beautiful lactescent tree, growing 30 or 40 feet high; its foliage is not unlike that of the orange tree, but more glossy and polished and of a bright green color. Its branches spread widely into a broad head; its flowers are dioecious, small, pale yellowish green; the barren are about 12 in number, borne in a very short, almost sessile, racemose panicle. The fruit has about the size and appearance of a large orange, yellow when ripe and roughened on the outside, containing a mucilaginous fluid, insipid and uneatable. The sap of the young wood and leaves is milky, and contains a large proportion of caoutchouc; the color of the wood is a bright yellow; its grain is fine and elastic, on account of which property it is employed by the southern Indians for bows. The young branches, beset with sharp, straight thorns, have suggested the employment of the tree for making live hedges, which succeed admirably where the winters are not so severe as to kill the annual growth. Treated as a hedge plant, it has many excellent characters but in order to form a compact growth, two shearings in a season are requisite. It is easily cultivated and propagated, and pieces of the root planted out in the nursery, with the tips just exposed above the earth, will readily grow; seeds procured from fertile trees may be sown in broad drills, a quart of seed producing at least 5,000 plants. The bark affords a strong fibre of a flaxy character and the bark of the root is used by the country-people of the Southern States as the material for a yellow dye.

OSAGES. A French corruption of "Waz-hazhe," their proper name, a tribe of North American Indians of Siouan origin, now as the Osage Nation occupying a reservation in northeast Oklahoma on the east bank of the Arkansas River. In the 17th century they were living in an extensive region between the Arkansas and Missouri rivers, and were early allies of the French, distrusted by, and in frequent warfare with, the neighboring Cherokee, Chickasaw, Creek, Choctaw and other Indians. The first historical notice of the Osage comes from Marquette (1673) who places them on the Osage River, where they remained until their removal in the 19th century farther westward. In 1714 the Osages formed an alliance with the French against the Foxes, who were badly defeated at Detroit. From this time on they appear to have been at almost constant war with the surrounding tribes in some of whom their very name inspired terror. At the beginning of the 19th century nearly half

of the Great Osage, under Big-track, migrated to the Arkansas River district. In 1804 the Arkansas Osage were estimated to number about 600, the part of the tribe left behind on the Osage River about the same number; and the little Osage somewhat less. But Morse, in 1821, Porter in 1829, the United States Indian Office in 1843, all estimated the Osages as from 4,000 to 5,000. In 1906, after the division of the tribal land and trust fund provision, there were still about 2,000 Osages under the care of the Indian Office. By a treaty between the United States and the Osage Nation, the latter in 1808 conceded to the former all their lands east of a line running south from Fort Clark to the Arkansas River, and those west of the Missouri River, comprising the present State of Missouri and the northern part of Arkansas. Again in 1825, in 1839 and 1865 their territory was gradually reduced and finally confined to their present reservation by act of Congress in 1870. The Osage Nation is said to be the richest community in the world. They own nearly 1,500,000 acres of land, worth not less than \$10 an acre. Besides this they have in the United States treasury \$8,562,690 derived since 1808, mainly from the judicious sale of superfluous lands. By Act of 28 June 1906 an equal division of the lands and the funds of the Osage was provided for.

OSAKA, ō-sā'kā, or **OZAKA**, Japan, the second largest city of the empire, and one of the three imperial cities, on the island of Hondo, at the mouth of the Yodo in the Gulf of Osaka, 20 miles by rail southeast of Kobe, and 27 miles southwest of Kioto. It is the least picturesque of Japanese cities, but is the foremost commercial mart of the entire Orient. The city covering an area of 27 square miles lies upon either bank of the river Yodo and upon an island in the middle of the river; the many intersecting canals and the bridges (over 1,000) spanning these give the Venetian effect. The rich business and manufacturing section is on the south bank of the river, and the western quarter is monopolized by the shipping interests. The island in the midst, which is the heart of the city, bears the poetical name of Nakanoshima, while anciently Osaka itself was known as Naniwa, meaning "dashing waves."

In the upper town, the fine castle, the granite of its walls of astonishing size, was constructed by Hideyoshi's orders in 1583. In its construction between 30,000 and 60,000 laborers were employed night and day for three years. The palace, built afterward in its precincts and destroyed in the civil war of 1868, was perhaps the most magnificent structure in Japan. Another notable edifice is the Sumiyoshi temple founded by the consort of the 14th emperor. Among modern buildings are the Mint, the central post office and the new Bank of Japan, a most imposing edifice. The fine modern harbor protected by a mole has a depth of 28 feet at low water, and hundreds of steamers and sailing craft ply between its wharves and the ports of Formosa, Korea and China. Osaka is the headquarters of the Osaka Chosen Kaisha line. There is an excellent street railway system, and a belt line half encircles the city. Cotton spinning is the principal of its numerous manufacturing industries; three-fourths of the operatives are women and girls; other important manufactures are those of iron and

steel products, glass, boots and shoes, bricks, chemicals, matches, tobacco and clocks; ship-building is also a considerable industry. The foreign settlement is on the deltaic island of Kawaguchi. Osaka was opened to foreign trade and residence in 1868. Destructive fires visited the city in 1910 and 1912. Pop. (1920) 1,252,972.

OSCAR. See **ESKER**.

OSAWATOMIE, ō-s-a-wōt'ō-mē, Kan., city in Miami County near the Osage and Pottawatomie rivers, and on the Missouri Pacific Railroad, 60 miles southwest of Kansas City, Mo. Its name comes from the two rivers mentioned. It is in a stock-raising and agricultural section, and in a natural gas belt. A few settlers were in this section about 1850, but in 1855 the place was organized by the Emigrant Aid Society as a "free-State settlement John Brown (q.v.) was interested in this settlement, and for a time lived on a farm nearby. On 30 Aug. 1856 the town was attacked by a band of pro-slavery sympathizers; John Brown and his friends made a vigorous resistance, but were finally overcome. A monument has been erected in commemoration of this event and there is a park known as the John Brown Memorial Park. The city is the division headquarters for the Missouri Pacific Railroad, and has the railroad shops, machine shops, flour mills and large stock yards. It is the seat of the State Insane Hospital opened in 1866, which has over 1,000 patients each year. Some of the prominent buildings are the city library, city hall, the Agnew Opera House, a Masonic temple, the churches and schools. The city adopted the commission form of government in 1914. It owns and operates the sewage, water and electric-lighting plants. Pop. 4,772.

OSBORN, Bradley S., American naval officer: b. Rye, N. Y., 16 Aug. 1828; d. 6 May 1912. He went to sea at 10, and served in the Chinese navy as coxswain, in the Argentine navy as commander, and was an admiral in the Mexican navy. In the Civil War he served under Du Pont, Worden and Farragut, receiving honorable mention by the latter. As volunteer naval scout in the Spanish-American War he was the first to discover the proximity of Cervera's fleet off Curaçoa, 14 May 1898, for which he received the thanks of the government. He served in the Arctic and Antarctic oceans and in 1900 he became flag-officer commanding the United States Veteran Navy with the rank of commodore. He published 'Osborn's Hand Book United States Navy' (1864); and 'United States Veteran Navy List' (1900).

OSBORN, Henry Fairfield, American palaeontologist: b. Fairfield, Conn., 8 Aug. 1857. He graduated from Princeton University in 1877 and in 1880 was assistant professor of anatomy there; from 1891-1910 was professor of zoology at Columbia University and on 4 Dec. 1906 was elected secretary of Smithsonian Institution, but declined the office. He was vice-president of the American Museum of Natural History (1901-08); trustee, 1901; and president since 1908. He explored for fossil vertebrates in western United States from 1891; in Fayum desert, Egypt, 1907; was active in founding New York Zoological Park under auspices New York Zoological Society as chairman executive committee (1896-1903, 1907-08); vice-president 1897-1909; president since 1909. Since

1900 he has been palæontologist of the United States Geological Survey. He has published 'From the Greeks to Darwin' (1894); 'Evolution of Mammalian Molar Teeth' (1907); 'The Age of Mammals' (1910); 'Men of the Old Stone Age' (1915); over 400 scientific papers, addresses and memoirs on zoology, vertebrate palæontology, comparative anatomy, embryology, zoogeography, anthropology, evolution, etc.

OSBORN, Herbert, biologist, entomologist and teacher: b. Lafayette, Wis., 19 March 1856. He was educated at Iowa State College and occupied positions from assistant to professor of zoology and entomology there 1880-98. He was State entomologist of Iowa 1898; professor of zoology and entomology, Ohio State University 1898-1916; research professor thereafter. Among his professional writings are 'Pediculi and Mallophaga of Man and Domestic Animals' (1891); 'Insects Affecting Domestic Animals' (1896); 'The Hessian Fly in the United States' (1898); 'The Genus *Scaphoideus*' (1900); and many articles in scientific journals.

OSBORN, Sherard, English author and navigator: b. Madras, India, 25 April 1822; d. London, England, 6 May 1875. He entered the navy in 1837 and was ordered to the East Indies, where at 17 he commanded a ship in the blockade of Quedah. In 1849 and in 1852-55 he was in command of one of the ships in the expeditions of Austin and Belcher sent in search of Sir John Franklin. He served in the Crimean War; in China, and Japan in 1857-59; and in 1862 commanded a squadron for the suppression of piracy. He was made rear-admiral in 1873. He wrote 'Stray Leaves from an Arctic Journal' (1852); 'Quedah: Stray Leaves from a Journal in Malayan Waters' (1857); 'The Career, Last Voyage, and Fate of Sir John Franklin' (3 vols., 1860); 'The Past and Future of British Relations in China,' etc.

OSBORN, Thomas Ogden, American lawyer: b. Jersey, Ohio, 1832; d. Washington, D. C., 27 March 1904. He was graduated from the Ohio State University in 1854 and then studied law. At the outbreak of the Civil War he organized and became colonel of the 39th Illinois Volunteers; commanded four regiments at the capture of Fort Sumter, and rose to the rank of major-general of volunteers. He returned to his practice after the war, was treasurer of Cook County, Ill., and manager of the National Soldiers' Home; he served as member of the commission appointed to settle disputed claims between United States and Mexico, and in 1874-85 was United States Minister to Argentina.

OSBORNE, Dorothy, English letter writer: b. 1627; d. 1699. She was the daughter of Sir Peter Osborne and married Sir William Temple in 1655. Her husband's schemes are said to have been aided by her and she was a friend of Queen Mary II. But it is in her letters, written to Temple during her prolonged engagement while her parents were delaying her marriage, that the world's interest in her centres. These letters to her fiancé form a superlative correspondence which is universally admired, and the few that appeared appended to Courteney's 'Life of Temple' called forth Macaulay's high praise. A fuller collection of these delightful letters was edited and published (London 1888) by E. A. Parry under the title of 'The Love

Letters of Dorothy Osborne,' a later edition appeared in New York in 1901, and in *Everyman's Library*. The charm of this 17th century correspondence retains its freshness to this day.

OSBORNE, John E., American public official: b. Westport, N. Y., 19 June 1864. He received a high school education and at the age of 16 was apprenticed to a druggist in Vermont. Subsequently he was graduated in medicine at the University of Vermont. He removed to Rawlins, Wyo., was appointed assistant surgeon of the Union Pacific Railway, established a wholesale and retail drug establishment in 1882 and since 1884 has been engaged in raising livestock. He served one term as member of the Wyoming territorial legislature and in 1888 was chairman of the territorial penitentiary commission. In the same year he was elected mayor of Rawlins, and from 1893 to 1897 was governor of Wyoming. He was delegate to the Democratic National Convention of 1896 and served as member of the 55th Congress in 1897-99. In the latter year he was Democratic candidate for United States senator in the Wyoming legislature. Since 1912 he has been a member of the Democratic National Committee. On 21 April 1913 Mr. Osborne was appointed First Assistant Secretary of State, from which post he resigned 14 Dec. 1916. He was a candidate for the United States Senate at the November elections of 1918.

OSBORNE, Oliver Thomas, American physician: b. New Haven, Conn., 14 Nov. 1862. He received (1884) his M.D. degree at Yale and that of A.M. in 1900. He did post-graduate work (1885) at Leipzig, and (1886) he started to practise medicine at New Haven. He was made professor of therapeutics at Yale Medical School in 1911, then professor of materia medica, therapeutics and clinical medicine. He has been chairman of the medical board of Gaylord Farm Tuberculosis Sanatorium. From 1908 he has been editor of the therapeutic section of the *Journal of the American Association*. He was a member of the revision committee of the United States Pharmacopœia. He has written 'Diphtheria' (1890); 'Therapeutic Uses of Organic Extracts' (1902); 'Introduction to Materia Medica and Pharmacology' (1906); 'Mixtures of the United States Pharmacopœia' (1913); 'The Prevention and Treatment of Infections' (1915).

OSBORNE, (Samuel) Duffield, American author: b. Brooklyn, N. Y., 20 June 1858; d. 20 Nov. 1917; graduated at Brooklyn Polytechnic Institute in 1875; at Columbia in 1879; Columbia Law School in 1881; received the degree of A.M. from Columbia in 1882, and practised law in New York 1881-92. He was assistant secretary and, later, acting secretary of the Brooklyn department of city works in 1893-94, and spent much of the following years in travel and archaeological research in Italy, Sicily and Tunis. He published 'The Spell of Ashtaroth' (1888); 'The Robe of Nessus' (1890); 'The Secret of the Crater' (1900); 'The Lion's Brood' (1902); 'The Angels of Messer Ercole' (1907); 'Engraved Gems: Signets, Talismans and Ornamental Intaglios ancient and modern' (1912); also many short stories, essays, poems and archaeological papers in periodicals.

OSBORNE HOUSE, a large English villa, formerly the residence of Queen Victoria,

situated near East Cowes in the Isle of Wight and where she died, 22 Jan. 1901. Edward VII, to whom it was left, presented it to the nation. Part of it is used as a convalescent home for officers of the army and navy, and part as a naval college.

OSBOURNE, Lloyd, American author: b. San Francisco, Cal., 7 April 1868. He was educated at Edinburgh University, traveled extensively and, accompanying his step-father, Robert Louis Stevenson, to Samoa, was at one time United States consul there. He wrote in collaboration with Stevenson 'The Wrong Box' (1889); 'The Wrecker' (1892); and 'The Ebb Tide' (1894). Among his own works are 'The Renegade'; 'The Queen vs. Billy' (1900); 'The Motor-Maniacs' (1902); 'Three Speeds Forward' (1906); 'The Adventurer' (1907); 'Infatuation' (1909); 'The Kingdoms of the World' (1911); 'A Person of Some Importance' (1913), and in conjunction with Austin Strong, two plays.

OSCANS. See **OSCI**.

OSCAR I (JOSEPH FRANÇOIS BERNADOTTE), king of Sweden and Norway: b. Paris, 4 July 1799; d. 8 July 1859. He was educated at the Lycée Louis le Grand and after his father had been chosen Prince-Royal of Sweden (see BERNADOTTE) he joined him in that country, and was proclaimed Duke of Sudermania. During the reign of his father he was three times, in 1824, 1828 and 1833, viceroy of Norway, where he made himself popular by his good administration. He afterward continued to study in retirement until the death of his father (4 March 1844) the social and political questions of the day. Parliamentary reform, Jewish emancipation, the freedom of the press and great economic development, were notes of his reign. He resigned the government in 1857 to his eldest son (afterward Karl XV). He wrote several works on political subjects, one of which, 'On Penal Laws and Establishments for Repression,' has been translated into French and German. He also composed an opera, and various other pieces of music. Oscar II (q.v.) was his third son.

OSCAR II, king of Sweden and Norway up to 1905, after that of Sweden: b. Stockholm, 21 Jan. 1829; d. there, 8 Dec. 1907. He was a grandson of Napoleon I's famous general, Marshal Bernadotte, king of Sweden. He was trained in the navy and at the University of Upsala, and ascended the throne in 1872, in succession to his brother, Charles XV. That the severance of the union between Sweden and Norway in 1905 was peaceful was in no small way due to the tact of King Oscar, and he declined to permit any prince of his house to be a candidate for the throne of Norway. He was recognized as a talented sovereign, speaking at least 10 languages, being well versed in naval and military history and general literature, and winning laurels as critic and poet. Among his writings are 'Some Contributions to the Military History of Sweden 1711-13' (1859-65); 'Memories of the Swedish Fleet' (1858), and translations from the German of Goethe's 'Tasso' and Herder's 'Cid.' He was elected an honorary member of the Berlin Academy and of the Imperial Society of Naturalists of Moscow. His collected works appeared in

1875-90. They were rendered into German by Jonas (verse 1877, 1888; prose 1891).

OSCEOLA, ōs-ē-ō'lā, or **AS-SE-HE-HO-LAR**, that is, 'Black Drink,' Seminole chief: b. near the Chattahoochee River, Ga., 1804; d. Fort Moultrie, S. C., 30 Jan. 1838. His paternal grandfather was a Scotchman. After his father's death his mother married a white man named William Powell, from which circumstance he has been mistakenly regarded as a half-breed under that surname. He was not a chief by descent or even by formal election, but he early manifested qualities of leadership. He showed his boldness in opposing the cession of the Seminole lands in Florida. But his passive opposition was roused in 1835 to open hostility; his wife, the daughter of a fugitive slave, was seized and carried into slavery; in his anger Osceola threatened the Indian agent, General Thompson, so rudely that he was seized, imprisoned and kept in irons for six days. Osceola precipitated the second Seminole War by massacring Thompson and four others a few months later, 28 Dec. 1835. His men who had killed Major Dade and his 110 soldiers on the same day were unsuccessful (31 December) in a fight with Clinch, but they took refuge in the Everglades, emerging now and again, as in the assaults on Micanopy and Fort Drane, never winning a battle, but always led with great skill and daring, and keeping the country in terror. Two years after, October 1837, he was seized by Gen. Thomas Jesup, with whom he was conferring under a flag of truce, and who excused his treachery by Osceola's alleged disregard of treaties. With several followers he was imprisoned at Saint Augustine, and then at Fort Moultrie, where broken in spirit by the betrayal, he died in a few months.

OSCEOLA'S REBELLION. See **SEMINOLE WAR**.

OSCI, or **OSCANS** (Greek, *Opikoi*), an Italian people who appear to have been the original occupants, at the earliest known period, of central Italy from Campania and the borders of Latium to the Adriatic. The Oscans were subdued by the Sabines, a people from the Apennines on the north, of whose previous history little is known and who probably adopted the language and customs of the conquered, with what modifications cannot be ascertained. The Oscan language was closely allied to the Latin, of which it was probably a parent stock. It appears to have been spoken in the provinces long after Latin became the official language and it was used officially long after the Roman conquest.

OSCILLATING CURRENT. See **ELECTRICAL TERMS**.

OSCILLOGRAPH, a form of D'Arsonval galvanometer, having a reflecting mirror, in which the moving parts are so light and the range of movement so small that the rapid variations in alternating and pulsating currents are easily followed by the ray of light reflected from the mirror. By reason of the persistence of vision, the rapidly moving spot of light actually appears to the eye as a complete curve of current or pressure from an alternating current dynamo. Consult Robinson, L. T., 'The Oscillograph and Its Uses' (in Transactions of the American Institute of Electrical Engineers, Vol. XXIV, New York 1905).

OSCINES, ős'i-nēz, a group of passerine birds possessing highly developed vocal organs, and including most of the "singing-birds" of the world. See ORNITHOLOGY.

OSCOTT (ös'kòt) **COLLEGE**, near Birmingham, England, a Roman Catholic institution founded in 1752 as a college and seminary for priests. It played a considerable part in the education of English Catholics when they were yet excluded from the English universities. The school is also called Saint Mary's Seminary. The courses in secular subjects qualify for the degree of B.A. in the London University.

OSCURA MOUNTAINS. A range in the southeastern part of Socorro County, N. Mex. It rises out of the wide desert east of the Rio Grande, presenting to the west a very steep front, 3,000 feet high, of rugged granite slopes surmounted by cliffs of east-dipping limestone which constitutes the summit and east slope. The length of the range is about 20 miles. Highest summit is Oscura Peak, altitude 8,732 feet. Profitable mines of silver lead occur at the north end of the range and the abandoned copper camp of Estey is on its southeastern slope.

OSEL, é'zél, or **OESEL**, Esthonia, an island in the district of Saaremaa-Osel in the mouth of the Gulf of Riga and after Seeland the largest island in the Baltic. It is 45 miles long; area, 1,010 square miles. The principal town, Arensburg (pop. 5,000), is on the southeast coast. The coast is generally bold and the interior undulating. The soil, gravelly and not naturally rich, becomes productive by careful culture, and raises corn for export, hemp and flax. The pastures are good, the forests large, the fisheries valuable and its breed of ponies is celebrated. Pop. 66,000, chiefly Esthonian. Successively in the hands of Danes, Swedes and (1721) Russians, it was captured in 1918 by the Germans during the Great War.

OSGOOD, öz'güd, **Samuel**, American soldier and legislator: b. Andover, Mass., 14 Feb. 1748; d. New York, 12 Aug. 1813. He was graduated from Harvard in 1770, engaged in a mercantile career, but public affairs absorbed much of his attention, and in 1775 he was a captain of minute-men at Lexington. For a time he acted as aide to Gen. Artemus Ward, but in 1780 entered the Continental Congress, where he served until 1784. In 1785-89 he was commissioner of the United States Treasury, the first to occupy that office; and in 1789-91, Postmaster-General. Later he was speaker of the New York assembly and in 1801-03 supervisor in New York. From 1803-13 he was naval officer at the port of New York.

OSGOOD, **Samuel**, American clergyman and author: b. Charlestown, Mass., 30 Aug. 1812; d. New York, 14 April 1880. Graduated from Harvard in 1832, and from the Cambridge Divinity School in 1835, he was later editor at Louisville (Ky.) of the *Western Messenger*, was pastor of a Unitarian church at Nashua, N. H., in 1837-41, and of the Westminster Church, Providence (R. I.), in 1841-49. From 1849 until his resignation in 1869 he was pastor of the Unitarian Church of the Messiah, New York. In 1870 he took orders in the Protestant Episcopal Church. Among his publications

were 'Studies in Christian Biography' (1851); 'God with Men' (1853); 'American Leaves' (1867).

OSGOOD, **William Fogg**, American mathematician: b. Boston, 10 March 1864. He was graduated (1886) at Harvard and studied (1887-89) at the University of Göttingen, then (1890) at Erlangen. He was appointed instructor of mathematics (1890-93), then assistant professor of mathematics (1893-1903) and since 1903 professor at Harvard. From 1899-1902 he was editor of *Annals of Mathematics* and (1909-10) of *Transactions of the American Mathematical Society*, being president of the latter society 1904-05. He has written 'Introduction to Infinite Series' (3d ed., 1906); 'Lehrbuch der Funktionen-theorie' (1905-07); 'First Course in Differential and Integral Calculus' (1907); 'Madison Colloquium Lectures' (1914), besides numerous monographs published in the mathematical journals.

OSGOODE, **William**, Canadian jurist: b. England, 1754; d. 1824. He was educated at Christ College, Oxford. After a brilliant course in law he was called to the bar and in 1792 removed to Upper Canada, where he became the first chief justice of that colony. He co-operated with Governor Simcoe in organizing Upper Canada and in 1794 was made chief justice of the province of Quebec. He resigned his post in 1801 and returned to his native land, where he afterward filled several important public appointments. He is the author of 'Remarks on the Laws of Descent' (London 1779).

O'SHAUGHNESSY, ò-châ'ně-sí, **Arthur William Edgar**, English poet: b. London, 14 March 1844; d. 30 Jan. 1881. In 1861 he became a junior assistant in the library of the British Museum, and in 1863 assistant in the zoological department. He won recognition as an authority in herpetology. But he was better known as a poet, his volumes being 'An Epic of Women' (1870); 'Lays of France' (1872), a free paraphrase of the *lais* of Marie de France; 'Music and Moonlight' (1874); and (posthumously) 'Songs of a Worker.' With his wife he collaborated in an admirable children's book, 'Toyland' (1875). Consult the 'Life' by L. C. Moulton (1894).

OSHAWA, ösh'a-wə, Canada, town and port of entry of Ontario County, Ontario, near Lake Ontario, and on the Grand Trunk, Canadian Pacific and Canadian Northern railroads, 33½ miles northeast of Toronto. Its harbor on Lake Ontario is called Sydenham. Its industries include manufactories of engines and machinery, agricultural implements, foundry products, furniture, flour, leather, carriages, white wear, musical instruments, etc. Pop. (1921) 11,552.

O'SHEA, ò-sha', **Michael Vincent**, American educator: b. Le Roy, N. Y., 17 Sept. 1866. He was graduated (1892) at Cornell and was appointed professor of psychology and education at State Normal School, Mankato, Minn. (1892-95). He became professor at Teachers' College, Buffalo (1895-97), and professor of education at the University of Wisconsin (1897-). He has given numerous lectures on education in America, England and Scotland. In 1910 he was chairman of the International Congress of Home Education at Brussels, and

was president of the Society of College Teachers of Education (1911-12). He has written 'Aspects of Mental Economy' (1900); 'Education as Adjustment' (1903); 'Dynamic Factors in Education' (1906); 'Linguistic Development and Education' (1907); 'Social Development and Education' (1909); 'Every-day Problems in Teaching' (1912); and is joint author of 'The Child and His Spelling' (1914), etc. He was editor-in-chief of 'The World Book Encyclopedia' and editor of the *Wisconsin Journal*.

OSHIMA, ō-shē-mā', Japan, a name signifying "great island," applied to numerous island dependencies of the empire. The chief are (1) Oshima or Vries Island southwest of the entrance to the bay on which stand Tokio and Yokohama; (2) Oshima off the southwest extremity of Hokkaido, opposite Fukuyama; (3) Amami-Oshima one of the largest islands of the Liu-Kiu Archipelago (q.v.).

OSHKOSH, Wis., city, county-seat of Winnebago County, on Lake Winnebago at the mouth of the Upper Fox River, and on the Chicago and Northwestern, the Chicago, Milwaukee and Saint Paul and the Soo Line railroads, about 75 miles northwest of Milwaukee and 85 miles northeast of Madison, the State capital. It was settled in 1836, and in 1853 was chartered. The city was greatly damaged by fires in the years 1859, 1866, 1874 and 1875. It is in a region where there has been extensive lumbering interests, and although the forests have disappeared in some sections lumber is still a leading industry. The chief manufactures are lumber and lumber products, as furniture, matches, sash, doors, matches and blinds, trunks, carpets, wagons and carriages. It manufactures also machine products, grass twine, rugs, carpets, flour, canned goods, tobacco, boilers, washing machines, gas engines, cement miners, truck cabs, toys, typewriters and agricultural implements. The capital invested in industry is \$12,375,000 and the total output is valued at \$17,500,000. About 6,500 hands are employed in the industries. The bank resources amount to \$12,672,000, with clearings aggregating annually \$26,198,727. It has a large trade, as the city is the commercial centre of a considerable portion of Winnebago and the adjoining counties. Lake Winnebago is noted for its fish and sportsmen find in the vicinity good hunting grounds. Yachting in summer and iceboating in winter are favorite sports on this lake. The prominent buildings are the government building, city hall, courthouse and the churches and schools. It has Saint Mary's Hospital and about three miles distant are the State Northern Hospital for the Insane, the county hospital for the incurable insane and the county almshouse. The city is also the home of three remarkable sculptural works—a statue of Carl Schurz, a bronze statue of the Indian Oshkosh and a bronze group in honor of city Civil War soldiers. Oshkosh is the seat of a State normal school and has public and parish schools and a public library. The city is under the commission form of government. The assessed valuation in 1919 was \$35,410,880, with a tax rate of \$1.95 per \$100. Pop. (1920) 33,162.

OSIANDER, ō-zē-ān'dēr, **Andreas** (classified form of **HESEMANN**), Lutheran theologian: b. Gunzenhausen, near Nuremberg, 19 Dec. 1498; d. Königsberg, 17 Oct. 1552. As first

evangelical preacher at Nuremberg, he exerted himself in furthering the Reformation and Lutheranism, taking part against Zwinglius on the subject of the Lord's Supper. He was also present in the conference at Marburg in 1529 and at the Diet of Augsburg (1530). His refusal to consent to the Augsburg interim in 1548 cost him his position at Nuremberg. By Duke Albert of Prussia, on whom one of his sermons had produced a strong impression, he was appointed preacher and first professor of theology in the newly-erected University of Königsberg and vice-president of the bishopric of Samland. Meanwhile, in 1549, he became involved in a theological dispute, which was embittered by his obstinacy. In a discussion, 'De Lege et Evangelio,' he maintained that justification is not a judicial or forensic act in God, but contained something of a subjective nature, as the imparting of an interior righteousness, brought about in a mystical manner by the union of Christ with men. These views he continued to maintain till his death. Consult Moller, 'Andreas Osianders Leben und ausgewählte Schriften' (1870).

OSIER, ō-zhēr, the popular name of those species of willow (q.v.) which are used chiefly for basket-making and other wickerwork. They are of low bushy growth and they are the more valuable in proportion to the length, slenderness, suppleness and toughness of their branches. The common osier (*Salix viminalis*), a common native of wet alluvial grounds in many parts of Europe, is cultivated to supply material for basket-makers and is often planted to prevent the banks of rivers from being washed away. See **WILLOW**.

OSIRIS, ō-sī'ris, in Egyptian mythology, meaning "full of eyes," the Greek form of the word, "Hesri" or "Asiri." He was the son of Seb, the Earth, and Nut, the Sky, the brother and husband of Isis and the father of Horus. He is styled the Manifestor of Good, Lord of Lords and King of the Gods. At Abydos was one of his most sacred shrines, and tradition said that there his head had been buried. Great pilgrimages were made to this city and the dead were brought from far-distant parts to be buried in its sacred soil. In the Egyptian theogony he represented the sum of beneficent agencies, as Set of evil agencies. Osiris, after having conquered all Egypt, established good laws and institutions and becoming a sort of culture divinity to the people whom he found in ignorance and barbarism according to tradition, fell a prey to the intrigues of his brother Set. Osiris set out to visit the whole world and continue his mission of culture, and it was during his absence that Set took advantage of conditions and set himself to undo the good done by Osiris. On the king's return Set plotted to destroy him. To do this, he secretly took his measure and had a fine box made exactly his size. This he brought to a feast at which Osiris would be. He offered to make a present of the box to any one who would fill it exactly. Osiris finally got into the box, on which Set and his accomplices shut it and threw it into the Nile, down which it floated to the sea. After a very long search Isis found the body and brought it back to Egypt. Set again got it, cut it and scattered the parts over the land, up and down the river. Isis gathered them up

and buried them and each burial place became sacred. He is represented under many different forms and compared sometimes to the sun and sometimes to the Nile. In particular his soul was supposed to animate a sacred bull called Apis and thus to be present continually among men. Sometimes he is represented as a man crowned with a mitre, a globe, a lotus-flower or an elephant's trunk; sometimes with the body of a man and the head of an ox, ibis or other animal; sometimes he holds a stick, sometimes a phallus in his hand. He holds in some representations a whip in one hand and a scourge in the other. He has frequently the horns of a bull. Mythologically he resided in the under-world and was the ruler of the dead.

The worship of Osiris was introduced into Rome but the rites proceeded to such an excess of licentiousness that it was at length prohibited by law. Consult Budge, Wallis, 'The Gods of the Egyptians' (London 1904); Erman, 'Die Aegyptische Religion' (Berlin 1905); Wredemann, 'Religion of the Ancient Egyptians' (New York 1897).

OSKALOOSA, ōs-ka-loo'sa, Iowa, city, county-seat of Mahaska County, on the Chicago, Burlington and Quincy, the Iowa Central and the Chicago, Rock Island and Pacific railroads, about 65 miles southeast of Des Moines. It was settled in 1843 and incorporated in 1853. It is the commercial centre of a fertile agricultural and stock-raising region. In the vicinity are large deposits of coal, limestone and fire-clay. The chief industries are flour milling, manufacturing vitrified brick, wagons, iron and brass goods, fire hydrants, furnaces, silos, caskets, heaters and woolen goods. It has a large meat-packing plant and coal and brick yards. The principal buildings are the post office, the church, school and library buildings. A bronze statue of the Indian chief Mahaska adorns the principal square. The educational institutions are the Penn College, opened in 1873 under the auspices of the Friends, the Oskaloosa College, under the auspices of the Disciples of Christ, a business school and a public library. The Society of Friends of the State of Iowa hold their annual meeting here. Pop. 9,466.

OSLER, ōs'lēr, Britton Bath, Canadian lawyer: b. Simcoe County, Ontario, 1839; d. 1902. He was educated at Toronto University and was called to the bar in 1862. He practised for some time at Dundas and at Hamilton but removed to Toronto in 1882. He soon acquired a national reputation as an expert lawyer in criminal cases. In 1885 the Dominion government secured his services in the trial of Louis Riel, and for many other cases of nation-wide interest.

OSLER, SIR Edmund Boyd, Canadian financier: b. Tecumseh Parsonage, Ontario, 1845; d. Toronto, 4 Aug. 1924. He was educated at Dundas. In 1896 he was president of the Toronto Bond Trade and was head of the Toronto financial house of Osler and Hammond. He was president of the Dominion Bank of Canada and director on the boards of numerous industrial enterprises and director of the Canadian Pacific Railway Company. He was created a knight in 1912 and was member of the Dominion House of Commons for West Toronto after 1896. In 1896 he was one of the

representatives of Canada at the Congress of Chambers of Commerce held in London.

OSLER, SIR William, Canadian physician: b. at Bondhead, Tecumseh, Ontario, 12 July 1849; d. Oxford, 29 Dec. 1919. He studied at Trinity College, Toronto, the Toronto School of Medicine and McGill University, where he graduated M.D. in 1872. He continued his studies at University College, London, Berlin and Vienna and was appointed professor of physiology and pathology in McGill University, Montreal, and to the chair of clinical medicine in the University of Pennsylvania in 1884. He was chosen as the Galstonian lecturer in the Royal College of Physicians, London, England, in 1885, and as the Cartwright lecturer in the College of Physicians and Surgeons, New York, in 1886. In 1889 he was appointed professor of the principles and practice of medicine in Johns Hopkins University and chief physician to the Johns Hopkins Hospital, Baltimore, positions which he resigned in 1904 upon his appointment as regius professor of medicine in the University of Oxford, England. A writer of international repute in various American and European medical journals as well as in other fields, he is the author of 'Clinical Notes on Smallpox' (1876); 'Histology Notes' (1882); 'Cerebral Palsies of Children' (1889); 'Principles and Practice of Medicine' (1892); a standard modern work which had reached a fifth edition in 1903; 'Chorea and Choreiform Affections' (1894); 'Lectures on Abdominal Tumors' (1895); 'Angina Pectoris and Allied States' (1897); 'Cancer of the Stomach' (1900); 'Science and Immortality' (1904); 'Counsels and Ideals' (1905); 'Thomas Linacre' (1908); 'A Way of Life' (1914), and is editor of 'A System of Medicine' (2d ed., 1915). He was created a baronet in 1911.

OSMAN DIGNA, ōs-mān' dig'na ("Osman the Bearded"), Sudanese chief: b. 1836; d. 1900. He was of Turkish extraction, a slave trader who suffered financial losses because of English interference with his trade; raised an army in 1881-82 to assist Arabi Pasha against the British; as chief of the sheiks of Eastern Sudan contributed largely to Gordon's capture and death by blocking the approach to Khartum, through Suakim; was the hero of a long and costly siege at Tokar in 1887-88; joined the Mahdi in the rising of 1899, and in 1900 was captured and imprisoned at Rosetta.

OSMAN NURI PASHA, noo'rē pāsh'ā, called GHAZI, "the Victorious," Turkish general: b. Amasia, Asia Minor, 1837; d. Constantinople, 5 April 1900. He saw service against the Druses in 1860 and in Crete in 1867-69, fought in the Yemen campaign of 1871, became marshal in 1876 and in the war with Russian, after bold and brilliant manœuvres, occupied Plevna, which he was forced to surrender 10 Dec. 1877, in spite of his heroic attempt to break through the forces of his besiegers. He was returned to Turkey after the Treaty of San Stefano, entrusted with the reorganization of the Turkish army and was Minister of War 1880-85 and marshal of the palace after 1880. Consult Levaux, 'Ghazi Osman Pasha' (1891). See RUSSO-TURKISH WAR.

OSMANIE, ōs-mā'ne-ā, Imperial Order of. See ORDERS, ROYAL.

OSMANTHUS, genus of trees of the natural order *Oleaceæ*, of which about 13 species are indigenous to North America, China and Japan. The species *O. americanus* is called devilwood in southern United States. It attains a height of 45 feet and a diameter of one foot. Other species are grown as ornamental shrubs in China and Japan.

OSMELITE, the same as **PECTOLITE** (q.v.).

OSMIUM, a metallic element of the platina group, commonly found with iridium (q.v.) and the heaviest and most infusible of metals. It was discovered by Tennant in 1804. Osmium-iridium is found in Neoyanskite and Syfferskite as very hard black grains; as a cubic or obtuse rhombohedral crystal it is bluish white, with violet lustre and greater hardness than glass. The element has the atomic weight 195 and the high specific gravity of 22.5. Osmium can be fused only by the heat of an electric arc. It forms three chlorides, OsCl_3 , OsCl_4 and OsCl_5 ; the oxides, OsO , Os_2O_3 , OsO_2 , OsO_3 and OsO_4 , commonly called osmic acid, which has pungent and poisonous vapors, is extremely volatile and is a powerful oxidizer. In alloy with iridium, osmium is used for pointing gold pens.

OSMOSIS, the diffusion of fluids through membranes. If a septum composed of either organic (such as a bladder) or inorganic (such as porous earthenware) be interposed between two liquids holding different substances in solution, the liquids will pass through the septum carrying some of the matter in suspension with them; that is, they will diffuse one into another. This phenomenon is called osmosis. The liquids pass through the interposed medium at different rates, gradually getting slower until, they are said to be balanced. If a bladder filled with a solution of sugar be immersed in water, seven parts of water (by weight) will enter the bladder while one part of sugar escapes into the water. The action of the liquid parting with its soluble matter is called endosmosis, the flow of the liquid receiving it exosmosis. Both must act simultaneously, one cannot exist independently of the other; together they constitute the phenomenon of osmosis. Endosmosis usually takes place in the direction of the denser liquid, although there are some exceptions, such as ether, alcohol, etc., which act like liquids heavier than water. This diffusion has variously been explained by capillary attraction, unequal absorption and chemical action, but the real explanation of osmosis appears to be along the lines of the kinetic theory of gases, which exert a pressure quite analogous to that of dissolved substances. In order to have osmosis take place the liquids on either side of the interposing septum must be of unequal osmotic pressure. See **CHEMISTRY**.

Osmosis plays an important part in plant physiology. The plant cell consists of a mass of protoplasm enclosed within a flexible organic membrane (the cell wall) and enclosing a fluid. This membrane is permeable to water and generally, though not always, to all substances it may hold in solution; but the protoplasm itself is only permeable to water containing such substances as it requires for its nutrition—it would seem to be endowed with the power of selection. Thus cells in different plants or cells in different parts of the same plant possess very different powers of osmosis

The osmotic pressure varies from two atmospheres in rare cases to 100 in certain tissues exposed to much loss of water by evaporation or by the presence of a medium of high osmotic pressure. The pressure within a cell may be measured by putting it in a medium which just causes it to show signs of losing its contents; another method depends on the fact that a soluble lowers the freezing-point of its solvent by an amount proportional to its osmotic pressure. Water is the only solvent in plant life. When a cell becomes full or swollen it is said to be turgid, but this turgidity is constantly relieved by osmosis taking place from cell to cell and by final evaporation. As soon as the osmotic pressure in one cell falls below that of a cell or cells with which it is in juxtaposition, osmosis takes place and thus a fair degree of equilibrium is maintained. The supply of food-stuffs is kept up in a like manner. Osmotic pressure is enhanced by electrolytic dissociation (see **DISSOCIATION**) which takes place in plant life on account of the presence of acids and salts (electrolytes) of various kinds which are found in solution both in and surrounding all plant life. The phenomena of osmosis still present a fertile field of research for the scientific mind. See **ABSORPTION**; **SOLUTIONS**. Consult Findlay, A., 'Osmotic Pressure' (New York 1913); Jost, L., 'Lectures in Plant Physiology' (2d Eng. ed., Oxford 1914); Morse, H. N., 'Osmotic Pressure of Aqueous Solutions' (Washington 1914); Philip, J. C., 'Physical Chemistry: Its Bearing upon Biology and Medicine' (New York 1913).

OSMUN, Thomas Embley ("ALFRED AYRES"), American orthoepist: b. Montrose, Ohio, 26 Feb. 1834; d. New York, 26 Oct. 1902. He was graduated from Oberlin College and later studied medicine in Paris and Berlin. In 1859 he returned to the United States and settled in New York. Resolving to make a life-work of the purification of the English language as used in the public press, he became an authority on the use of English and also attained distinction as a dramatic critic. Subsequently he taught elocution, and in 1891 he appeared as Shylock in Boston and other New England cities. He was one of the editors of the 'Standard Dictionary.' He published 'The English Grammar of William Cobbett' (1884); 'The Orthoepist' (1880); 'Some Ill-Used Words' (1901), etc.

OSMUNDA, a genus of tall ferns with large stout rootstocks and sporangia borne on the veins of reduced leaves. One species, the royal fern (*O. regalis*), is cultivated on account of its elegant appearance. It grows in clumps of two to five feet in height, and is well adapted for open moist places, where the soil is rich and shade thin, or even where full sunlight falls.

Other well-known species occurring in America are the cinnamon fern (*O. cinnamomea*) and the interrupted fern (*O. claytoniana*).

OSNABRÜCK, ös'nä-brük, Germany, a town of Hanover, Prussia, on the Haase, 70 miles west of Hanover. In the old town the streets are generally narrow and the houses low; but the new quarters have wide and handsome streets and fine residences. The chief buildings are the ancient Protestant churches of Saint Catherine and Saint Mary; the Roman Catholic

cathedral (13th century); the Protestant and Roman Catholic gymnasiums, the town-house, with statues (1889-90) of German emperors on the façade; the Friedenssaal (Hall of Peace), restored in 1890; the museum (1889), the new hospital, teaching colleges, libraries and the commercial school. Osnabrück has iron and steel works, railway workshops, machine-shops, iron-foundries, wire-works, paper-mills, flax and cotton-mills, bleach-fields, tile-works, breweries, etc. There are iron mines and stone quarries in the vicinity. Osnabrück gave its name to the coarse linen known among English-speaking people as osnaburghs. It was created a see in 1888, and in 1082 was surrounded by walls. It afterward entered the Hanseatic League, but never became a free imperial city. The negotiations for the Peace of Westphalia, which ended the Thirty Years' War, were carried on here. Pop. 65,967.

OSORIO, Manoel Luiz, mǎ'noo-él loo-éth' ō-sō-rē-ō, Brazilian soldier: b. near Pelotas, Brazil, 10 May 1808; d. Rio de Janeiro, Brazil, 4 Oct. 1879. He entered the army at an early age and in the Civil War in Rio Grande do Sul, 1839-45, he attained distinction. In the campaign in Uruguay in 1851-52 he was again prominent and at the outbreak of the Paraguayan War in 1865 was made commander-in-chief, but was superseded by Caxias in 1866. He was made lieutenant-general in 1867 and continued to serve until 1869, when he was seriously wounded. He entered politics after the war, became senator in 1877, and from 1878 until his death was Minister of War. He was created Marquis of Herval by the government, but his chief title of honor was "O Legendario" (the Fabulous) bestowed upon him by his soldiers for his bravery.

OSPREY. See FISH-HAWK.

OSSA, ōs'a, Greece, the classic name of Kissavos, a mountain 6,408 feet high, in the northeast of Larissa, overlooking the Gulf of Saloniki. The Vale of Tempe separates it from Olympus, 9,794 feet high, and to the southeastward is Mount Plessidi—ancient Pelion—5,308 feet high. These three mountains are renowned in Greek mythology, and the classic phrase "piling Ossa upon Pelion" refers to the giants Ephialtes and Otus arranging to place Ossa upon Pelion to aid them in reaching the summit of Olympus. This conception is said to have been suggested by the conical form of Ossa and the flat summit of Pelion. The seats of the Centaurs and Giants are located in the neighborhood of Ossa and Pelion.

OSSEIN, ōs'ē-in, the organic basis of bone allied to gelatine. If a bone is placed in acid, 20 per cent hydrochloric, the inorganic matter (salts, etc.) is dissolved out and by repeated washings only the organic matter remains. This retains the shape of the bone without its hardness. It will not dissolve in cold water, but if boiled with dilute mineral acid it reduces to gelatine. Ossein is closely related to, if not identical with, the collagen of the connective tissues. Bone also contains a mucoid and an albuminoid. See BONE.

OSSETES, ōs'ets', a people of the central Caucasus region, supposedly of Iranian origin, because of their native name (Iron) and phys-

ical characteristics, although there is a tradition among them that they came from the region of the Don in Russia. They are tall, and have broad heads, but are by no means as attractive appearing as their neighbors of the Caucasus. Their religion is an admixture of Mohammedanism and Christianity. Consult Chantere, 'Recherches anthropologiques dans le Caucase' (Paris 1887), and Kovalevski, 'The Customs of the Ossetes' (in the *Journal of the Royal Asiatic Society*, 1888).

OSSETIC (ös-sët'ik) **LANGUAGE**, an Iranian language spoken by the Ossetes (q.v.) of the Caucasus. It is analytic in form. Cases are formed by postpositions. There are three verbal tenses, past, preterite and future, with indicative, optative, subjunctive and imperative moods. Auxiliary verbs aid in the formation of compound tenses and of other voices than the active. The chief dialects are Ironish or Irish, and Tagaurish, Digorish and Taulish. Of these Tagaurish is the most important for the linguist and phonologist. Folktales and the Bible represent the literature of this remnant of an ancient language. Both the Armenian and Russian alphabets are used. The language is spoken by about 125,000 people. Consult Hübschmann, 'Die Sprache der Osseten' (Strassburg 1903); Rosen, 'Ossetische Sprachlehre' (Berlin 1844); Sjögren, 'Ossetische Sprachlehre' (Saint Petersburg 1844).

OSSIAN, ōsh'i-an, or more correctly, **OISIN**, appears in Gaelic literature and legend as the son of Finn, or Find, the hero of what has been styled the Fennian or Oisianic cycle of tales and poems current in Ireland and the highlands of Scotland. Finn is the hero of all these tales and poems, as Arthur is of the Arthurian cycle; Oisín is his poet and bard, as well as his son. This Oisianic cycle exists side by side with a heroic cycle which consists of about 30 tales, forming one of the most complete epic cycles to be found in any literature. They are tales of battle, narratives of adventure, all circulating round the person of the hero Cuchulaind. They are mixed prose and verse and many of them are extant in manuscripts written about the 12th century. The Oisianic cycle is of a different period. Finn, the heroic figure, is a less legendary and mythological personage than Cuchulaind; he lives in the 3d century at the time when the Romans occupied Great Britain and moves through the story almost like a historical character; the supernatural is relatively infrequent in his adventures, and he fights his battles as a leader of mercenaries engaged, after the country has been conquered, in keeping the native races of Scotland in check. These stories are found in good manuscripts of the 15th century and their style points to the fact that a stage of culture has been reached by the rude inhabitants of North Britain very different from that described in the heroic cycle, where Medb, queen of Connaught, contends with Mac Nessa, king of Ulster, for the possession of the brown bull of Cualnge, and Cuchulaind defends Ulster single-handed and discomfits with his unaided sword the valor of whole armies. In the heroic cycle the characters are completely mythological, but they are distinctly described as to their dress or arms. In the Oisianic cycle the figures of the actors become more vague; there is an exaggeration in the reported exploits of the

warriors, although the excitement of the hunt and the riot of the royal drinking bout, as therein depicted, are evidently clear transcripts from the primitive life of their period. There is one important point to be noted with regard to these two types of ancient Celtic literature in Scotland. They are as distinct in style, color and development as in their *dramatis personæ*. They belong to different eras, and their heroes never meet on the same stage; the hero of the earlier cycle has vanished when Finn, the Oisian warrior, comes upon the battlefield.

This is a very important point in deciding one of the virulent literary controversies of the 18th century. The Celtic legends as they were preserved orally or in manuscript attracted the fancy of James MacPherson (q.v.), a Scottish schoolmaster, who published what he averred to be translations from "the Gaelic or Erse" in the shape of "Fragments of Ancient Poetry" (1760), and subsequently produced 'Fingal' (1762) and 'Temora' (1763), afterward collected into a single volume under the title 'The Poems of Ossian.' There was much merit in these works as poems. The descriptions of scenery were often beautiful and approaching the sublime, and the wildness of highland mountain and lake was vividly portrayed. But apart from the want of detail in the account given of the dress, buildings and social life of the personages introduced there was one circumstance that proved these poems to be anything but translations of a connected "Gaelic or Erse" composition. The heroes of the heroic cycle were made to mingle with the heroes of the Oisian cycle in the narrative. And this was not all. MacPherson never produced during his lifetime the original poems which he averred were in his possession. After his death, however, some manuscripts were found in which fragments from both periods of genuine ancient poetry were found patched together in a cento with some very indifferent Gaelic of his own, and so arranged as to form a sort of counterpart to his 'Poems of Ossian.' The more recent studies in Gaelic literature have furnished us with this solution of the Ossian controversy; and have made it apparent that, while MacPherson might have been at liberty to fuse certain ancient poems, as Fitzgerald has done in his Omar, to produce a beautiful romance of his own, he committed a grave and unpardonable error in attempting to forge originals to support his claim that his work was a translation pure and simple. Consult Simpson, 'Poems of Ossian' (1857); McLauchlin, 'The Book of the Dean of Lismore' (1862); Nutt, 'Ossian and the Ossianic Literature' (1899); Rolleston, T. W., 'Myths and Legends of the Celtic Race' (New York); Windische, 'Die Altirische Sage und die Ossianischen Gedichte' (1878).

OSSIAN-NILSSON, ös'si-an-nēls'sön, Karl Gustaf, Swedish poet; b. Lund, 1875. He received his education at the university of his native town and entered the teaching profession. He won a literary reputation in 1900 with 'Fem dikter' and 'Masker.' This was enhanced by other works such as 'Hedningar' (1901); 'Ornar' (1902); 'Svart och hvitt' (1904); 'Amerikaner och byzantiner' (1905); 'Orkester' (1907); 'Flygskeppet' (1910); 'Prästgården' (1911); the novels 'Barbarkögen' (1908; 7th ed., 1913); 'Slätten' (1909); 'Hafvet' (1910);

'Odets man' (1912); Lille Benjamin' (1913); and the metrical drama 'Fågel Fenix' (1912).

OSSIFICATION, the process of bone formation, which in all cases essentially consists of the deposition of earthy or calcareous matter. It may exhibit two modes of occurrence. Bone may be formed by the deposition of earthy or osseous material in fibrous membranes, that is, in tissues composed of fibres and cell elements. The flat bones of the skull or cranium are developed in this first manner. No granular or intermediate stage is observable in this process, the earthy matter being simply deposited in spaces which result from absorption. In the second mode, exemplified in the formation of the long bones of the skeleton, the osseous material is deposited in a primary basis of gristly or cartilaginous kind. Ossification in this latter instance is, therefore, said to begin in cartilage, just as in the previous case it began in membrane. The process of ossification in cartilage exhibits activity at several distinct and marked points of its extent. These points are the active centres of bone-growth, and are hence called centres of ossification. The limy material is, therefore, diffused from these centres throughout the extent of cartilage, the blood vessels of the adjoining parts bringing supplies of material from which the earthy matters are deposited within the cartilaginous basis. The corpuscles of the cartilage are seen to be arranged in verticle rows, and the calcareous matter, deposited in the form of granules, is thrown in around them. The nuclei of the cartilage cells are left unossified, a space also being kept free around each nucleus, which becomes one of the lacunæ or minute cavities seen in a microscopic section of bone-tissue. The first deposits of bony matter are of an irregular and thick description, this form of ossification, if persisted in, producing cancellated bony tissue; while by a subsequent process of absorption of the spaces in the cancellated tissue, and by the further deposition of bony matter, the irregular tissue is converted into compact bone. The gradual growth of bone takes place by a continual development of the cartilaginous basis between the various centres of ossification, and in this new basis earthy matter is as continually being formed.

True ossification may also occur abnormally in living textures and as the result of diseased conditions. This is particularly likely to take place in the muscles, as in those of the right shoulder of the infantryman, which is irritated by his rifle, or of the thighs of the cavalryman. The ossification of the muscles may also form part of a progressive general disease. Deposits of limy matter may take place within the coats of blood vessels, rendering them friable and readily ruptured. The valves of the heart may become calcareous, and calcareous degeneration may even affect tumors and other products in themselves of abnormal nature. A distinction ought to be made between mere calcification as just indicated, and true ossification, or the formation of bone. But in either case the deposition of limy matter forms the basis or essential feature. The gall-bladder may thus be converted into a hard limy sac or bag, and even the pericardium or investing sac of the heart may occasionally exhibit a high degree of calcification. See BONE.

OSSINING, ős'sin-ing, formerly **SING SING**, N. Y., village in Westchester County, on the Hudson River, and on the New York Central and Hudson River Railroad, about 30 miles north of New York. It was settled about 1698, incorporated as a township 2 May 1845 and as a village some years later. The name Sing Sing, by which it was known until 1901, comes from an Indian word meaning a stony place. One of the State prisons is located here, just outside the village limits, and is known as Sing Sing prison; hence the villagers desired a change of name, and chose Ossining. The village, located upon rocky hills, overlooks Tappan Bay and a long and beautiful part of the river. In the early part of the 18th century silver, copper and some gold was found here, and considerable capital was expended in developing mines which never proved productive. The chief manufactures are shoes, leather, machinery, foundry products, pills, porous plasters, drills and plated goods. The trade is chiefly in its own manufactures and farm products. Some of the places of interest are the Croton Aqueduct Arch, 88 feet span and 70 feet above water, and the arched highway bridge. The State prison, a large white building made of dolomite, a coarse marble quarried nearby, was founded in 1826. Capt. Elam Lynds brought here 100 convicts from the State prison at Auburn and put them to work to wall themselves in. Men only are confined here. The village has long been noted for its educational institutions; it has Holbrook, Saint John's and Mount Pleasant Military academies, the Roman Catholic Foreign Mission Seminary, Ossining Seminary for young women, public and parish schools and a public library. There are six churches. The two banks have a combined capital of about \$200,000. The government is vested in a president and nine trustees. The president and three trustees are elected each year. The village owns the waterworks. Pop. 10,739. Consult Ingersoll, 'Hudson River and Catskill Mountains'; Scharf, 'History of Westchester County' (Philadelphia 1886).

OSSOLI, ős'sō-lē, **Sarah Margaret Fuller**, **MARCHIONESS**, American writer: b. Cambridgeport, Mass., 23 May 1810; d. off Fire Island beach, 19 July 1850. She was remarkable for her precocity and her association with Emerson and other eminent literary men, rather than for her own productions. She was taught at six to read Latin, and early made herself acquainted with English and Continental literature. She taught in public and private schools in Boston and Providence, and frequently visited Brook Farm (q.v.), though she never resided there and had no confidence in the final success of that enthusiastic experiment. In 1840-42 she was editor of the *Dial*, which numbered Emerson and other distinguished writers among its contributors. In 1844 she removed to New York and became literary critic of the *Tribune*. In that capacity she worked effectively toward the increase of public interest and the improvement of public taste in literary, artistic and other matters. She visited Europe in 1846, met there leaders in literature, art and philanthropy, married in 1847 the Marquis d'Ossoli; was in Rome during the siege of 1849, when she served in the hospitals; embarked with her husband for New York but perished almost in sight of

port during a severe storm. The position she took in the American literary world of the time would perhaps be not wholly intelligible to one now reading much of what she wrote. Her critical articles are her best by far, many being brilliant and exhibiting what Higginson calls "the power of putting a high thought into a sentence." She strove to abolish the colonial spirit in American thought and letters, and contemporaries bear witness to the reality and excellence of the service. Consult the 'Memoirs' by Emerson, Clark and Channing (W. H.) (1852); and the biographies by Howe (1883); and Higginson (1884); 'American Men of Letters' series.

OSSUNA, ô-soo'nā, **Duke of**. See **OSUNA**, **PEDRO TELLEZ Y GIRON**, **DUKE OF**.

OSTADE, ôs'tā-dē, **Adrian van**, Flemish painter: b. Haarlem, 10 Dec. 1610; d. there, 2 May 1685. He studied under Frans Hals. His pictures exhibit an exact imitation of nature, and contain realistic representations of subjects which in other hands would have been mean or commonplace, such as the interiors of ale-houses or kitchens, with Dutch peasants smoking, quarreling or drinking, and he puts such expressions into the heads of his characters that their coarseness is lost in our admiration of their truth and animation. His coloring is rich and clear, his touch spirited and free and all his works are highly finished. His later works were somewhat overwrought. He was also a good etcher; Jan Steen was a pupil of his. Among his pictures (which are generally small) may be mentioned 'The Smoker'; 'The Drinker'; 'The Dancer.' He also painted many portraits.

OSTADE, **Isack van**, brother and pupil of the preceding, Flemish painter: b. Haarlem, 2 June 1621; d. there, 16 Oct. 1649. He at first applied himself to paint the same subjects as those which had brought such a brilliant reputation to his brother, but soon abandoned taverns and kitchens for scenes in the open air, both summer and winter landscapes, and with such success that at the time of his death he was rapidly rising to be a rival to his brother. Original in style, his pictures are remarkable for good composition, masterly drawing and solid painting. Many of them are in England, where they were valued before his fellow-countrymen came to a knowledge of his genius. Among the most valued of them are 'A Village Inn'; 'View of a Frozen Canal'; 'Landscape and Cottages'; 'Village Scene' (showing cavalier on gray horse, horsemen with red cloak and post wagon); 'Winter Landscape in Holland.' The 'Halte de Voyageurs' and 'Vue de Village' were sold (1865) for upward of \$5,000 each.

OSTEITIS, inflammation of the substance of bone. In its chronic forms it may result in suppuration; in caries, a decay of the bone in particles; or in necrosis, a decay of the bone in slices. Removal of the diseased bone may be required.

OSTEN-SACKEN, ôs'tēn-sāk'kēn, **BARON Charles Robert**, Russian entomologist: b. Saint Petersburg, 21 Aug. 1828; d. 1906. He was educated in his native city and became connected with the Imperial Foreign Office in 1849. He came to the United States in 1856 as secre-

tary of legation at Washington and in 1862 became Russian consul-general at New York. In 1871 he resigned his public office but remained in the United States until 1877. With Mr. H. Loew he studied the Diptera of North America, and published numerous papers on this subject and two catalogues.

OSTEND, ōs-tënd', Belgium, a seaport town and pleasure resort, in the province of West Flanders, on the North Sea, 67 miles northwest of Brussels. Ostend is connected by rail with all parts of Belgium, France and Germany; and steamers ply regularly to and from London and Dover. It was strongly fortified prior to 1865, since when the fortifications have been replaced by fine promenades. It has a healthful situation, although on a low sandy coast, and is resorted to for sea bathing, etc., by about 50,000 visitors annually. Along the sea front is a massive digue or esplanade of stone and terra-cotta, three miles long, forming a fine promenade. The public buildings include the Hotel de Ville, three churches (one finished in 1883), an English church, large Kursaal, barracks, etc. The harbor is not easy of access, but has been greatly improved since 1898; the basins within are extensive, giving 32 feet at high water, and form the termination of a magnificent line of canals stretching like a network into the interior, and furnishing admirable facilities for commerce. The manufactures are unimportant, the chief being linen, sail cloth and tobacco. Shipbuilding is also carried on. Cod and herring fishing are considerable industries, and an important branch of trade is oysters, fattened here in large salt reservoirs, and transported as far as Paris. Ostend was founded in the 9th century, walled in 1445 and regularly fortified in 1585 by the Prince of Orange. In the great struggle to throw off the yoke of Spain it sustained a memorable siege from 4 July 1601 to 28 Sept. 1604, during which the besieged lost about 50,000 men, and the Spanish besiegers more than 80,000. Pop. 43,002.

During the Great War Ostend was for a short time the capital of Belgium; but it was captured by German forces on 15 Oct. 1914, suffered considerably at their hands and later from British air attacks.

In March 1919 the town of Ostend furnished the Minister of the Interior with a list of the sums claimed before the Peace Conference for reparation in respect of the war damage which the town had suffered. Ostend expended about 20,000,000 francs (\$4,000,000) in forced requisitions; while the damage done to public buildings was valued at 57,000,000 francs (\$11,400,000), or a total of 77,000,000 francs (\$15,400,000), without counting the losses caused to private individuals. During the war Ostend was bombarded 187 times, and 271 persons were killed and 436 injured in the shelling.

OSTEND MANIFESTO, The, a term used in the diplomatic history of the United States since 1854. In that year, 9 October, a dispatch was forwarded to the United States government by the American ministers at the courts of Great Britain, France and Spain, who had met in the city of Ostend, by the government's request, to discuss the Cuban question. The dispatch declared that, if Spain would not sell Cuba, self-preservation required the United

States to take the island by force, and prevent it from being Africanized like Haiti. They advised offering \$120,000,000 for the island. The suggestion was not approved in the United States by statesmen or politicians and was strongly condemned.

OSTEOLEPIS, a genus of fossil long, slender crossopterygian fishes, peculiar to the Lower Old Red Sandstone of Scotland. It is characterized by smooth rhomboidal scales, by numerous sharply pointed teeth and by having the two dorsal and anal fins alternating with each other. This, with *Diplopterus*, etc., constitutes the family *Osteolepidæ*, represented in America by the genus *Megalichthys* of Carboniferous and Permian formations.

OSTEOMALACIA (also called *MALACOSTEON* and *MOLLITIES OSSIUM*), a disease occurring most frequently in women, but sometimes in men, characterized by softening of the bones through progressive disappearance of the earthy salts. It affects the different parts of the skeleton, and deformities are often caused by it. It is mainly confined to adults, does not ordinarily attack the aged, and among women is likely to be associated with pregnancy, or to follow child-bearing, abstinence from which affected women should strictly practise. It may progress for years, and then end in fatal complication with lung disease, or through exhaustion. The causes assigned are many, but their determination is as yet incomplete. Surgery has sometimes proved more efficacious than medical treatment in this disease, which demands the most thorough hygienic care in all cases.

OSTEOLOGY, Human, that branch of anatomy which treats of bone or of bones. The bony element of the body is for the maintenance of form and motion, support of weight and muscles, and the protection of the internal organs. It is one of the hardest structures of the body, possessing a certain degree of toughness and elasticity. See *BONE*.

Development of Bone.—In the foetal skeleton the long bones of the limbs are cartilaginous. Hence there are two kinds of ossification, intracartilaginous and intramembraneous, and to those must be added the subperiosteal. In intracartilaginous ossification the cartilage-cells increase rapidly in number and arrange themselves in rows, the cells being closely packed and wedged together. The intracellular matrix of the cartilage is semi-transparent. Lying below this cartilaginous layer near the centre of ossification is a layer composed of osteoblasts. The bones of the vertex of the skull are entirely formed by intramembraneous ossification.

Marrow.—The marrow differs in composition at different periods of life and in different bones. In the young it is a transparent reddish fluid of tenacious consistency, free from fat, and contains minute roundish cells. In the shafts of the adult long bone the marrow is of a yellow color and contains a large quantity of fat and areolar tissue. In the flat and short bones, in the articular ends of the long bones, in the bodies of the vertebræ, in the base of the cranium, in the sternum and ribs, it is of a red color, consisting of albumen and extractive matter with a mere trace of fat.

Nourishment of Bone.—This is derived from the numerous blood vessels and lymphatic glands. Those of the compact tissue are derived from a dense network of vessels ramifying in the periosteum. From this membrane vessels pass into the minute orifices of the compact tissue.

Bones of the Human Body.—The skeleton of the adult consists of 206 distinct bones. The spine proper or vertebral column includes 26; the cranium, 8; the ossicles of the ear, 6; the face, 14; os hyoides, sternum and ribs, 26; upper extremity, 64; lower extremity, 62.

Long, Short, Flat and Irregular Bones.—The long bones, found in the limbs, are built to sustain the weight of the trunk and confer the power of locomotion. A long bone consists of a lengthened cylinder, a shaft with two extremities. The shaft is a hollow cylinder, the walls consisting of a dense compact tissue of great thickness. They are the humerus of the arm, radius and ulna of the forearm, carpus, metacarpus and phalanges of the hand; the femur of the thigh; tibia and fibula of the leg; tarsus, metatarsus and phalanges of the foot. Where a part of the skeleton is intended for strength and compactness and its motion is at the same time slight and limited, it is divided into a number of small pieces united together by ligaments. The separate bones are short and compressed, as, for example, the bones of the carpus and tarsus. These bones in their structure are spongy throughout except at their surface, where there is a thin crust of compact tissue. Where the principal requirement is either extensive protection or the provision of broad surfaces for muscular attachment, the osseous structure is expanded into broad, flat plates, as seen in the bones of the head, pelvis, foot and hand. The irregular or mixed bones are such as from their peculiar form cannot be grouped under the preceding heads. They are the vertebræ, sacrum, coccyx, temporal and sphenoid.

The spine is a flexuous and flexible column formed of a series of bones called vertebræ. They are 33 in number exclusive of those which go to form the skull, and have received the names cervical, dorsal, lumbar, sacral and coccygeal, according to the position they occupy; seven cervical, 12 dorsal, five lumbar, five sacral and four coccygeal. The sacral and coccygeal vertebræ consist at an early period of life of nine separate pieces, which are united in the adult, so as to form two distinct bones, the sacrum and the coccyx. Each typical vertebra consists of two essential parts, an interior solid segment or body, and a posterior segment or arch. The bodies of the vertebræ are piled one upon the other, forming a strong pillar, for the support of the cranium and trunk, the arches forming a hollow cylinder behind for the protection of the spinal cord. The different vertebræ are connected together by means of the articular processes and the intervertebral cartilages while the transverse and spinous processes form levers for the attachment of muscles. Between each pair of vertebræ apertures exist through which the spinal nerves pass from the cord. The peculiar vertebræ of the cervical arc the atlas and axis modified from the other vertebræ to admit of the nodding and rotary movement of the head. The atlas supports the globe of the head, the axis forming

a pivot upon which the head is rotated. To the atlas and axis are attached the muscles of the neck and spine.

The large triangular bone situated at the base of the vertebral column at the upper and back part of the pelvic cavity is called the sacrum (q.v.).

The coccyx, the extreme end of the spinal column, in shape resembles a cuckoo's beak. It is formed of four small rudimentary vertebræ. It articulates with the sacrum and is attached to the levator and sphincter-ani muscles, the gluteus maximus, and the coccygeus muscles.

The superior expansion of the vertebral column is called the skull, and includes the cranium and the face. See SKULL.

The hyoid bone is named from its resemblance to the Greek, *upsilon*. It is called the lingual bone because it supports the tongue. To it are attached the muscles of the throat.

The sternum is a flat narrow bone situated on the median line of the front of the chest, and to it are attached some of the muscles of the chest and abdomen, articulating with the clavicles and seven costal cartilages on each side.

The ribs are elastic arches of bone which, with the intercostal muscle, form the thorax. They are 12 in number on each side. The first seven are connected behind with the spine, and in front with the sternum through the intervention of the costal cartilages. The next three, or false ribs, articulate with the costal cartilage of the seventh rib; the next two, or floating ribs, are free. To the ribs are attached the muscles of the chest, abdomen, throat, back and diaphragm.

The anterior portion of the skeletal foundation, so to speak, of the arms, is called the clavicle, or collar-bone. See CLAVICLE.

The scapula forms the back part of the shoulder. It is a large flat bone triangular in shape, situated at the posterior aspect and side of the thorax between the first and eighth ribs. To it are attached the muscles of the shoulder, arm and thorax.

The humerus is the longest bone of the upper extremity. It consists of a shaft and two extremities, articulating above with the scapula and below with the ulna and radius. To it are attached the muscles of the arm, the forearm and thorax.

The ulna is a long bone placed at the inner side of the forearm parallel with the radius and articulating with the humerus, forming the elbow-joint.

The radius is situated at the inner side of the forearm parallel with the ulna, with which it articulates, forming at its lower end the wrist-joint. The ulna and radius form the attachment for nearly all the muscles of the arm, hand and fingers. See ARM.

The hand is subdivided into three segments, the carpus or wrist, the metacarpus or palm, and the phalanges or fingers. See HAND.

The os innominatum, or hip-bone, forms the side of the pelvic cavity. It is divided into three portions, the ilium, ischium and pubis. It articulates with its fellow of the opposite side, the sacrum and the femur. It forms the attachment of the muscles of the thigh, abdomen and pelvis.

The longest bone in the skeleton, to which are attached the muscles of the leg and thigh, is the femur (q.v.).

The patella (q.v.) protects the front of the knee-joint and increases the leverage of the quadriceps extensor muscle. The tibia, situated at the front and inner side of the leg, beginning at the knee, is long and narrow, with enlarged extremities, articulating with the femur, fibula and astragalus. The fibula is situated at the outer side of the leg, is smaller than the tibia, and forms with it the attachment of the muscles of the leg and foot. The bones of the foot consist of three divisions, the tarsus, metatarsus and phalanges. See FOOT; OSSIFICATION; OSTEOLOGY, COMPARATIVE. Consult Dwight, T., 'Clinical Atlas' (Philadelphia 1907); Fraser, J. E. S., 'Anatomy of the Human Skeleton' (ib. 1914); Gegenbaur, C., 'Lehrbuch der Anatomie des Menschen' (7th ed., 2 vols., Leipzig 1899).

H. H. BIEDLER, M.D.,

Johns Hopkins University Hospital.

OSTEOMYELITIS, inflammation of the inner lining membrane (endosteum) and the marrow-cavity of bone, a disease of rare occurrence, mostly following amputations, although occasionally following in the train of other diseases. It also follows wounds whereby the medullary canal is exposed to the air, such as gunshot wounds, compound fracture, etc. The inflammation is due to pyogenic infection, is generally acute and extends from the marrow to the osseous structure itself. Chills, sweats and high fever sometimes accompany the usual symptoms of pain and swelling, with a purulent discharge appear sloughs of tissue and dead bone. The disease usually ends fatally by general infection. Surgery alone is practicable in the direct treatment, with such medical and hygienic accessories as the physician may prescribe.

OSTEOPATHY. The essential features of osteopathy as a school of the healing art is its mechanical viewpoint of the bodily organism. The human body is a complete organism constructed after a definite mechanical plan of which every tissue, organ and part has a distinctive arrangement, position and function. Every unit of the structure is in mathematical concordance with all other parts and the whole after the manner of any complex and unified mechanism. Bio-physics and bio-chemistry of the organism explain the known and verifiable phenomena. It is upon this solid and modern scientific ground that the school of osteopathy has built its foundation.

It is a biologic axiom that structure determines and controls function. Given an intact structure, a mechanism that is mathematically correct, it is reasonable to infer that function will be normally operative. The osteopathic school accepts this as fundamental. If structure is distorted or disarranged, order or health accordingly will be impaired. It is obvious that gross derangement of the structure will disturb harmonious action of its parts; but osteopathic practice not only accepts this as true, but applies the same principle to all tissues, even to a minute degree. The development and application of this principle to every portion of the organism, the mechanical construction of the tissues and their possible innumerable dis-

placements and derangements, is the basis of the theory and practice of osteopathy.

The Body is a Vital Organism.—Biologically the human mechanism is something more than a mere machine; it is a vital organism. Therefore, it is conditioned from within, and every part conditions every other part and the physiologic unity of the whole. Although structure modifies and controls function, still the two are inseparable, for it is function that produces structure. Derangement of mechanism registers its effects structurally, and change in character of functioning will also be expressed structurally. The structural expression, if correctly interpreted, is osteopathically invaluable.

It may be said that life is function; and it is the function of self-repair that exemplifies the vital completeness of the body. The body contains inherently, active and potential, all the necessary properties for growth, development and repair. Nothing can be done that will add a morphologic or physiologic unit to the organism. But much can be accomplished to influence properties and forces that are disorganized to the point of functional discord, as well as to stimulate and develop active and potential ones.

The human body being an adaptable vital organism, the environment of structure and function comprises the essential feature in the field of therapeutics. Not only must the assemblage of the parts be precise in a mechanical sense, as is demanded of any mechanism, for it to operate normally, but function must be neither abused nor disused or else the functioning process will be abnormally conditioned. Both anatomically and physiologically considered disease is a condition of the organism. An harmonious environment, as expressed through sanitary and hygienic influences, is an essential requirement of normal functioning. The influence of these forces upon nerve impulse, circulatory channel and the chemistry of the body is basic to the physiologic action. Growth and development exemplify functional action of the organism, and depend upon not only an intact anatomical, but also upon a consonant hygienic and dietetic, environment. Thus upon broad, but nevertheless definite biologic grounds, the health problem primarily deals with the anatomic and physiologic adjustment of cell, tissue and organic environment. It is not a problem of extraneous or foreign stimulation or inhibition, but instead of biologic normalization, of the inherent and complete properties, active and potential, of the vital organism.

The Importance of an Intact Structure.—A diseased condition presents physiologic forces that are at variance from the normal as to time, rhythm, quantity. In other words they are natural forces but not normal forces. The structural mechanism may be distorted or mal-adjusted by physical forces, as any machine may be, so that order and harmonious action are not forthcoming, or physiologic functioning through environmental change and adaptation may also result in discord. In either instance it is evident that a deranged structure lowers resistance, impairs nutrition and thus predisposes to the many exciting causes of disease; for any condition or force that disturbs nervous equilibrium, vascular equalization or chemical co-ordination produces a definite effect upon the character of organic functioning. Then it is

equally evident that rectification of the structural derangement and functional environment is the logical remedy.

The tendency of the organism under all conditions is toward self-repair and physiologic unity. It is manifestly impossible to transfer a vital spark to the organism. Treatment of any kind whatsoever can go no further than a certain guidance or control of its bio-physics and bio-chemistry. This is the beginning and end of therapy; and in order for it to be really efficacious, it must be consonant with these forces, for the reparative and healing powers are inherent qualities.

An organ is an instrument for functioning, and the degree of its mechanical intactness within a definite minimum establishes a certain ratio of normal function. Beyond this minimum, with most organs, there is a superabundance of tissue that may be called the margin of safety. There is not only a superabundance of tissue, but also of mechanism, as instanced, for example, by inflammatory reaction, substitution, vicariation and adaptation upon the part of the various tissues. Thus the completeness of the structural plan, the physiologic inherent properties and, beyond all, the function of self-repair are basic considerations.

The Cause of Disease.—The essential thing in practice is to find the cause of disorder and remove it if possible. Osteopathy's claim to a school of the healing art rests with its establishment of a distinctive etiologic diagnosis of disease. Every school pays allegiance to the rich heritage of common medical knowledge. These facts are many but their value depends upon the interpretation and the use made of them. Osteopathy accepts this data and makes use of it in so far as the verifiable facts are applicable and demonstrable at the bedside. In addition to this, osteopathy presents considerable new material. But it is the osteopathic concept, the principles universally exemplified, that are of commanding importance. Every disease or disorder is in its final analysis a condition of the organism that is not compatible with the normal, must be in accordance with natural law and is scientifically demonstrable if the sequential chain can be elucidated. Osteopathy through its clinical research has clearly demonstrated the mechanistic origin of many disorders. This principle is applicable to every tissue of the body. Every structural derangement of tissue is at least potentially a cause for disease. If a definite order of the structure is an essential to health, then disorder of tissue will, in accordance to natural law, be followed by ill-health. Thus, osteopathically viewed, a fundamental cause of disease rests with the character of the bio-physics. The status of the osseous alignment, especially of the vertebræ which enclose and protect so many vital centres, the character of muscle tonus, the condition of the ligaments and the position and functional development of the viscera are all of basic consideration in the health problem. Conformation, configuration and poise, whether of spinal column, torso, abdomen, pelvis, or of the body as a unified mechanism, and the elasticity and resiliency of tissue, all attest physiologic principles of first importance. The intact anatomical condition exemplifies the primary hygienic law. Any divergence from this intactness is of first consideration to the osteopath.

There are many factors that will disorganize or disarrange the structural mechanism: over-fatigue, ill-habits, deleterious environment, insanitary conditions, unhygienic surroundings, dietetic errors, mental disturbance, prolonged exposure to cold or heat, trauma, etc. Traumatic injury is far from being the only cause of maladjustment. An imbalance of muscles, due to fatigue, a slumped posture, cold, etc., are common sources of mechanical derangement. Vital reacting to environment is always expressed structurally, of which abuse and disuse of function are everyday examples. The locality, character, extent, as well as the time factor, of the pathogenic changes are the important features.

These changes initiate a distinctive osteopathic pathology. The stress and strain concomitant with environmental reaction and adaptation, if carried beyond the normal limitations, is certain to disturb physiologic unity with a consequent lowering of tone and resistance of tissue. These are the first changes involving nerve impulse, circulation and chemism of the body. In other words, these are pathogenic factors that antedate and give origin to many well-known symptom groups and morbid states. This condition renders the bodily organism subject to the influences of pathogenic bacteria and other secondary and exciting causative factors of disease. Synchronously with lowered resistance and impaired nutrition a diminished immunity is certain to develop. The initial lesion is frequently a localized maladjustment of tissues that, either through its definite location involves innervation and circulation of a tissue or organ, or through its nutritive impairment favors multiplication of micro-organisms. Owing to the importance of the spinal structures and their functions much attention is given these tissues, although every section of the body is thoroughly examined, both structurally and functionally, in accordance with characteristic osteopathic procedure and the several other scientific methods.

Equally important are the action and freedom of nerve impulses, the character of vascular tissue and its unreserved flow, the integrity of the cerebro-spinal circulation, the unimpeded drainage, the complete elimination, the thorough co-ordination of chemical forces, and, through these, the ability of the organism to establish immunity. All of these are intimately interrelated; in fact, co-ordination and correlation of the organism as a concatenated whole, structurally and functionally is completely expressed by the function of self-repair and the power of the tissues to prevent infection. Historically, osteopathy is the first school to recognize the facts that functional integrity is dependent upon a mechanically intact structure and a harmonious environment and that chemical immunity may be thus established, and, moreover, what is of far greater importance, to actually apply this basic conception to the detailed bodily mechanism in its entirety.

The recognition of a distinct osteopathic etiology and pathology establishes a new and characteristic method of diagnosis, though all scientific methods of diagnosis are recognized and adapted in accordance with the osteopathic concept. The diagnostic characteristics of the osteopathic school are those features that are

dependent upon a deranged or maladjusted mechanism—maladjustment of the apposed interosseous tissues, tightening, thickening or laxness of ligaments, and adhesions and various changes in the articular tissues, contraction and contracture of muscles, displacement of organs and the innumerable grosser changes of spinal, pelvic and thoracic conformation—all of which can be shown distinctly to disturb functional integrity, are among some of the principal osteopathic signs and symptoms. Thence, in response to the vital reaction, through the media of nerves, circulation and chemical forces, there follow impairment of bodily equilibrium, of elasticity and resiliency of tissue, of dynamic and static requirements of joint functioning, of organic structure, function and relationship.

Significance of Osteopathic Adjustment.

—The body being a complete vital organism endowed with the wonderful function of self-repair, and even with an excess of structure and mechanism, is frequently capable, when disordered, of restoring functional integrity, but in other instances owing to severe or prolonged disturbance of structure or function extraneous aid must be instituted after the manner of structural, environmental, surgical or dietetic adjustment in order that a normal physiologic unity may assert itself—and this is osteopathy. Frequently when the correct osteopathic treatment is applied the commonly accepted natural history of disease is changed. The disorder may be either aborted, lessened or many possible complications prevented. Thus osteopathic prognosis comprises characteristic and distinctive factors. And the possibilities in the field of preventive medicine are greatly increased.

It should be emphasized that osteopathic treatment is neither a routine method nor a movement cure, but instead a definite manual adjustment of the maladjusted parts. Every treatment is as individual as the mechanical problems presented. These problems are innumerable, depending upon character and extent of tissue involved, whether vertebral, pelvic, torso, etc., the many secondary factors that may complicate the disease, and the various inherited and environmental conditions that may predispose or add to the disease picture. The treatment of a disorder is composed of many factors, and commonly speaking the value of a therapy is dependent upon a true evaluation of all the forces and processes that have entered into the production of the diseased condition. The characteristic feature osteopathically is the mechanistic one somewhat paralleled by the adjustment methods demanded in the restoration of any complex mechanism. But in the liberation and rectification of the dynamic forces when the structure is deranged (and that give origin to a morbid state that must necessarily precede the various symptoms or manifestations of disease), by adjustment of the tissues to a point of normalization and by attention to the maintenance of a harmonious regimen, one should not lose sight of the fact that there is something more than can be explained in terms of mechanism though this constitutes the solid groundwork of the biologic sciences. In reality the body is a vital organism.

Discovery of Osteopathy.—Dr. Andrew Taylor Still of Kirksville, Mo., discovered osteopathy. He was born in Virginia in 1828; d. 1917. Dr. Still was educated as a physician and surgeon of the regular school. When the Civil War broke out he was located at Baldwin, Kan., and served as a surgeon to the Northern forces. From an early period he had been a close observer of nature, spending much time and thought in natural history pursuit, and having a decided inclination to inquire into the why of things. In his early life the dissection of animals was of special interest to him, which later was followed by the dissection of many human subjects. Anatomy and the laws of nature therein expressed had been for 70 years or more the one commanding interest of his life. This combined with a distinct genius along mechanical lines laid the foundation for the science and art of osteopathy. One of his early inventions is an important part of the reaping machine.

At an early period in Dr. Still's professional career he lost several of his own children from cerebro-spinal meningitis. They had the best attention that medical skill could give. This seems to have been a great stimulus to his future life work. Dr. Still realizing that the doctors had done the best they knew how did not ascribe the tragedy to the inscrutable ways of Providence, but instead, fully believing that the practice of drug medication is basically wrong, set himself the task of discovering if possible a scientific method of therapy. This was the driving and commanding force that later developed into the school of osteopathy.

Dr. Still was a skilled surgeon of no mean ability, particularly as his art pertained to mechanical adjustments of fractures and dislocations. The restoration of function in this class of cases, especially the pronounced effect of these comparatively grosser corrections upon the liberation of vessels and nerves, followed by normalization of tissues, gives an inkling of the restorative properties of nature. This with his commanding knowledge of anatomical structure, particularly from the living or dynamic standpoint, with a decided tendency to investigate and experiment are additional factors that led to his discovery.

The osteopathic discovery came very gradually. In some of the first experiments it was found that pressure on the occipital nerves cures certain kinds of headache; that adjustment of the cervical and dorsal vertebræ will frequently cure goitre; that alignment of the lumbar vertebræ will cure many cases of dysentery; that correction of the spinal joints will be followed by restoration of partially paralyzed nerves of the legs. These with many other similar experiences over a period of many years were the early incidents that led to the discovery of osteopathy.

In the early days of osteopathic investigation Dr. Still arrived at the definite conclusions that disease is largely a condition of the mechanism depending upon the structural status of the tissues, that all remedies for relief and cure are contained within the organism, and that adjustment, normalization of structure and environment represents the remedial law.

In 1874 Dr. Still's discovery was definitely announced. He spent his remaining years in perfecting the idea and making practical that

the human organism is a self-reparative and self-recuperative vital organism; that by virtue of these attributes the organism contains, actively or potentially, the essential properties for growth, development, repair and cure; that normal circulation, nervous equilibrium and chemical co-ordination are the essentials of health; and that ill-health is initiated, active or predisposing, by some maladjustment of structure, bone, muscle or other soft tissue or organ, so that vascular tissue, nervous structure or chemical force is impaired. The impairment may be caused by trauma, environment, infection, diet, etc.

Dr. Still writes: "Osteopathy is based on the perfection of Nature's work. When all parts of the human body are in line we have health. When they are not the effect is disease. When the parts are readjusted, disease gives place to health. The work of the osteopath is to adjust the body from the abnormal to normal; then abnormal condition gives place to the normal and health is the result of the normal condition."

"Man cannot add anything to this perfect work nor improve the functioning of the normal body. Disease is an effect only. Man's power to cure is good at least in so far as he has knowledge of the right or normal position, and so far as he has the skill to adjust the bones, muscles and ligaments and give freedom to nerves, blood, secretions and excretions." Dr. Still has constantly emphasized the fact that the "rule of the artery is supreme," and that the beginning of disease is first characterized by interference to complete freedom of vascular channels.

The development of osteopathy has been dependent upon a more complete understanding of living anatomy, a detailed knowledge of every tissue in not only its mechanical relationship, but also of its functional significance. Disease being expressed by anatomical change, accompanied by functional perversion, from the norm, a thorough knowledge of the intact structure is demanded. In order to restore normal completeness of the mechanism, both the statics and dynamics of its component parts and of the mechanism as a whole must first be elucidated. This demands a certain skill of diagnostic ability as well as efficiency of manual adjustment.

Dr. Still says: "To repair signifies to readjust from the abnormal condition to the condition of normal. You as osteopaths can go no farther than to adjust the abnormal condition, in which you find the afflicted. Nature will do the rest. Order and health are inseparable, and when order in all parts is found, disease cannot prevail, and if order is complete and disease should be found, there is no use for order. If order and health are universally one in union, the doctor cannot usefully, physiologically or philosophically be guided by any scale of reason, otherwise."

"If health is perfect, it only proves perfect harmony in the physiological action of the body in all its parts and functions. Any variation from perfect health marks a degree of functional derangement in the physiological department of man. Efforts at restoration from the diseased to the healthy condition should present but one object to the mind, and that is

to explore minutely and seek variation from the normal.

"It is only the perfection of the organism and the connected oneness that is the keynote to osteopathic practice. Every part has a duty to perform not only for its own maintenance, but also for the health and harmony of the interrelated whole. This is part of the law of supply and demand, which is absolute through all nature. It is important to know the exact place that each organ and tissue occupies in its normal position. It is only by knowing the normal we are enabled to detect the abnormal. Each organ seems to be a creator of its own fluid substances. We must know the nerve and blood supply and the drainage."

"With anatomy in the normal properly understood, we are enabled to detect conditions that are abnormal. It may be that by measurement we can discover a variation one-hundredth of an inch from the normal, which, though infinitely small, is nevertheless abnormal. If we follow the effects of abnormal straining of ligaments, we easily come to the conclusion that derangements of one-hundredth part of an inch are often probable of those parts of the body over which blood vessels and nerves are distributed, whose duties are to construct, vitalize, and keep a territory, though small in width, fully up to the normal standard of health. My object is to emphasize the importance of looking after local causes that go on with their irritation."

Definite results in practically every field of disease were obtained before any possible laboratory demonstration could be secured, such as the scientific world has to-day, that clearly revealed the biologic integrity and completeness of the vital organism. Dr. Still suggested the antigens in the blood long before any one else, and also anticipated the fact of immunity. Not only did he emphasize the absolute importance of a free flow of pure blood and an unobstructed lymphatic drainage, but also of an uninterrupted nerve impulse as well as the circulation of the cerebro-spinal fluid. All of this he considered as fundamental requirements in order that health may be maintained. These are necessary attributes for self-growth, self-development and self-repair. They establish that a unified whole for every part is reciprocally conditioned.

Coexistent with this are the attributes of a physical mechanism. Vital functions are conditioned and amenable to the structural laws of physics. This fact determines the value of the science of osteopathy—its practicalness. Owing to the structural character of the organism, its definite plan and great complexity much attention is paid to anatomical minutiae. To adjust mechanically, as the art implies, requires an exact knowledge of structure and its expressed mechanical principles. This naturally enjoins considerable detail knowledge as well as experience and skill.

The term osteopathy is derived from the Greek: osteon, bone; pathos, suffering. This was suggested because the bony framework comprises an important part of the physical body, which frequently becomes maladjusted, resulting in impairment of the organism; and because the bones are used as levers for the adjustment of the tissues.

Legislation.—The legislative history of osteopathy comprises one of its interesting and important chapters. The writer is under obligations to the legislative department of the American Osteopathic Association for considerable of the following material.

Osteopathy received its first legal recognition in Vermont in 1896. In 1897 Missouri, Michigan and North Dakota legalized the practice. Iowa enacted a law in 1898, and South Dakota, Illinois and Tennessee in 1899.

The contention of regular medical practitioners who opposed these laws was that the osteopaths should take the regular medical examination. The evident prejudice against osteopaths of those making this contention was an argument against the fairness of such an arrangement, but it was evident to the public that osteopathy was really a separate and distinct science. Osteopaths were not taking a fundamental part of existing medical practice and calling it by another name just to avoid laws and educational standards, as has been since done as to osteopathy by variously named practices. The course of the early osteopathic college which required 20 months and did not pretend to prepare its graduates for major surgery compared very favorably with the then quite commonly prevailing course of 24 months in medical colleges in which time major surgery also was supposed to be covered. As to its differences from medical belief and practice, as a matter of fact it was so different that such of its fundamental ideas as that vertebræ are often subluxated and cause interference with spinal nerves and produce disease in the organs these nerves supply were ridiculed, at that time, by the medical profession. There was, thus, no confusion in the public mind as to osteopathy being distinctly different from the accepted idea of medical theory and practice and it was given separate recognition.

As new osteopathic schools sprang up over the country, some good, some mere diploma factories, and as the imitators and impostors that inevitably attach themselves to any worthy idea began to distribute themselves throughout the States, it became evident that the earlier laws recognizing osteopathy needed amplification in order that the public might be assured of efficient osteopathy practice and the earlier laws were variously changed and amended to this end.

By way of enacting a law which would be both fair to the osteopathic profession and at the same time raise the profession's standards and ensure the best possible osteopathic services to the public, in 1901, though there were but 13 osteopaths in Montana at that time, the Montana legislature, against the usual medical contention that osteopaths should be regulated by the medical board and persistent plans to bring that about, overwhelmingly sanctioned a bill which provided for a State board of osteopathic examiners. This board was to be composed of three graduate osteopathic physicians to be appointed by the governor of the State and whose duties would be to pass upon the school credentials of all applicants in "anatomy, physiology, chemistry, pathology, obstetrics and theory and practice of osteopathy and such other branches as are taught in well regulated and recognized schools of osteopathy and deemed

advisable by the board." This law was the first of its kind.

This form of law having been in consideration by those interested in other States was adopted in the years following in a number of States. Because of its fairness and efficiency in practical administration and its practical possibilities in continuously raising the standard of osteopathic practice and increasing the worth of the service that osteopathic physicians render the public, it has become the most common form of regulating the osteopathic system of practice. It has for years been the law which the osteopathic profession has favored in contradistinction to laws which force the osteopathic practitioner to be examined by boards composed entirely of medical men or even medical boards on which the osteopathic profession is given minor representation.

A recent resolution unanimously passed by the American Osteopathic Association in convention assembled outlines the profession's legislative stand: "That it is the sense of this association that medical examining boards on which osteopathy is given minor representation are not just to osteopathic physicians in their practical administration and that it is impossible for such boards to give examinations which are the most practical test of efficiency. . . .

"We endorse the Independent Board of Osteopathic Examiners as the fairest and most efficient medium for the regulation of osteopathic practice."

Under medical board regulation discrimination has been often practised against osteopathic applicants and justice been such a variable quantity that the osteopathic profession has, because of this, been consistent in asking for separate regulation, but, while this is true, it does not constitute the fundamental reason for the stand which the osteopathic profession has continuously taken in demanding separate regulation and examination of osteopathic applicants rather than regulation which causes osteopathic applicants to be tested by a medical examination given by drug school practitioners. The essential reason for the profession's contention against the latter arrangement is epitomized in the words of the above-quoted resolution,— "it is impossible for such boards to give examinations which are the most practical tests of efficiency." The reason that it is impossible is because of the distinct difference between the education received by an osteopathic physician through the better osteopathic college and the education received by the drug school practitioner through the medical college, a difference existing not in length or thoroughness or practicalness of course, for there the osteopathic college does not suffer by comparison with the average medical college. A difference which lies rather in character of education, the distinctive and definite nature and features of which do not confine themselves to the difference between the instruction in classes in materia medica and drug therapeutics in a medical college and the instruction in the classes in principles and practices of osteopathy which take their place in an osteopathic college. The fundamental distinction antedates the therapeutic phase for it is the etiologic diagnosis of human ailments that controls and determines therapy, and which viewpoint must necessarily permeate

all the medical sciences and render a distinctive, definite and harmonious interpretation of existing facts as they pertain to the broad etiologic concept upon which the system is built. Herein is contained the essence of the osteopathic school, and by virtue of its practical efficiency at the bedside the osteopaths claim the rights and privileges to provide for, develop and safeguard its basic principles.

This difference in character of education existing, it is the belief of the osteopathic profession as to State board tests,—that the same State board examination which tests the practical worth and fitness of the drug school practitioner to administer to the public does not and cannot, at least at the present time, best test the practical worth and fitness of an osteopathic practitioner to render osteopathic service to the public and vice-versa.

The prime object of all regulation of the practice of the healing art being to ensure to the public the best possible professional service, the test which does not and cannot ensure this has not conserved its end. As, because of the difference indicated, only those themselves having been osteopathically educated would be qualified to test as to whether an applicant possessed a practical working osteopathic education, the public is best served as to regulation of osteopathic practice by having State board of osteopathic examiners or committee provided.

Osteopathy, "A system, method or science of healing," as it is designated by a number of State laws is now regulated in its practice by all but a few of the States of the Union and by a number of the provinces of Canada. As the osteopathic colleges have continuously raised their standards and length of courses from the 20 months course of the early classes of the parent school to the present uniform four-year course, the various laws regulating the practice at present have come to indicate these increased standards.

The largely predominate form of regulation is the law providing for a State board of osteopathic examiners. These boards are composed entirely of osteopathic physicians. The following States have such boards of examiners: Arkansas, Connecticut, Florida, Georgia, Idaho, Kansas, Louisiana, Maine, Maryland, Michigan, Minnesota, Missouri, Montana, Nebraska, New Mexico, North Dakota, North Carolina, Pennsylvania, South Dakota, Tennessee, Vermont, Washington, the Territory of Hawaii and the province of Saskatchewan.

In the following States, osteopathy is recognized by having representation on the regular medical boards of examiners. The laws in these States are termed composite board laws: Arizona, Colorado, Indiana, Kentucky, Massachusetts, Mississippi, New York, New Jersey, Oklahoma, Oregon, Texas, Utah, Virginia, Wisconsin and Wyoming. California also has osteopathic representatives on the medical board, but the law is otherwise much different from the laws in the last-named list of States. Province of Alberta has a composite board.

Ohio and Rhode Island have osteopathic committees to pass upon the osteopathic applicants. Delaware and West Virginia and also in the province of British Columbia and Alberta the examining board is authorized to call in an osteopathic physician to assist in the examination of the osteopathic applicants, and the law

is so constructed that this can be done in Illinois, Iowa, Nevada, New Hampshire, South Carolina and the Territory of Porto Rico, the osteopathic physicians being examined and licensed in these States by the regular medical board. In Alaska the law stipulates there shall be no discrimination against any particular school. In Mississippi, Nevada, District of Columbia, and the Canadian provinces, except Winnipeg, that have not already been named, the practice is permitted, though neither authorized nor prohibited by statute. An adverse statute in Winnipeg is not invoked and the practice is permitted. In England, Ireland, Scotland, France, Germany, Sweden, Italy and South America countries osteopathic physicians are permitted to practice, medical regulations applying only in some limiting features.

Colleges and Organizations.—The parent college, The American School of Osteopathy, Kirksville, Mo., was established in 1892. Since then several other colleges have been founded. The present number includes, in addition to the above: College of Osteopathic Physicians and Surgeons, Los Angeles; Chicago College of Osteopathy; Philadelphia College and Infirmary of Osteopathy; Des Moines-Still College of Osteopathy; Massachusetts College of Osteopathy, Boston; Central College of Osteopathy, Kansas City; and Kansas City College of Osteopathy and Surgery. Upwards of 8,000 students have been graduated.

The minimum requirements for matriculation in the Associated Colleges is: "A diploma from a high school course or its equivalent education, together with satisfactory proof that the applicant is the lawful holder of such diploma and that the same was procured in the regular course of instruction." The course of study in an osteopathic college "shall cover four calendar years of not less than 32 weeks each year, and at least 10 months must have intervened between the beginning of any course and the beginning of the preceding course." The minimum required curriculum is a course of 4,320 hours covering the usual sciences taught in a medical college, but, of course, from the osteopathic concept.

The A. T. Still Research Institute, Chicago, is a scientific organization founded by the profession whose special purpose is the development of the science of osteopathy through laboratory investigation. Its buildings and laboratories are well equipped. Considerable research work has been prosecuted along osteopathic lines, which is from time to time published in bulletin form. An important part of the work to date has been experimental verification of the osteopathic lesion, the functional and organic effect of maladjusted structure, on animals. This has clearly demonstrated that structural perversion compromises organic integrity.

The American Osteopathic Association is the national organization, comprising several thousand members. Annual conventions are held. The Association publishes a monthly scientific journal, and a monthly popular journal, both devoted to the advancement and development of osteopathy. Each State and many of the cities have thoroughly established local societies.

Late Chairman Department of Education,
American Osteopathic Association.

OSTEOSTRACI. See OSTRACOPHORES.

OSTERHAUS, ös'tēr-hōus, **Hugo,** American naval officer: b. Belleville, Ill., 15 June 1851. He was graduated (1870) at the United States Naval Academy and rose in successive promotions till he became (1901) commander, captain (1906) and rear-admiral in 1909. After serving in the several squadrons he was appointed to the Naval Academy (1892-95, 1897-99 and 1901-03). He commanded the *Cincinnati* from 1904-05, was member of the board of inspection and survey (1905-07), commanding the second division, Atlantic fleet (1910) and commander-in-chief Atlantic fleet (1911). In 1913 he was retired.

OSTERHAUS, Peter Joseph. German-American military officer: b. Coblenz, Germany, about 1823; d. Berlin, Germany, 4 Jan. 1917. He emigrated to the United States and at the outbreak of the Civil War joined the Union army in which he was given rank as major of volunteers, subsequently attaining the rank of brigadier-general, and serving as chief of staff under Gen. Kirby Smith. He acted as United States consul at Lyons, France, after the war, but ultimately returned to Germany, where he engaged in manufacturing business. At the time of his death he was the oldest pensioner of the American army.

OSTERHOUT, ös'tēr-hout, **Winthrop John Vanleuven,** American botanist: b. Brooklyn, N. Y., 2 Aug. 1871. He graduated (1893) at Brown University and was instructor of botany there from 1893-95, teaching botany also at Woods Hole, Mass., 1894-95. He studied (1895-96) at the University of Bonn, then returning to America as instructor (1896-1901), assistant professor (1901-07) and associate professor (1907-09) at the University of California. He was assistant professor of botany (1909-13) at Harvard University, then becoming professor. He has written 'Experiments with plants' (1905); 'Agriculture for Schools of the Pacific Slope' (1909), in collaboration with E. W. Hilgard, besides many contributions to the botanical and bio-chemical periodicals.

OSTIA, ös'ti-ä, Italy, an ancient city of Latium, formerly the port of Rome, at the mouth of the Tiber, six miles from Rome by

the Via Ostiensis. It was founded by Ancus Martius in the 7th century B.C., who established salt-works at its site, which long continued to supply Rome and the neighborhood. Ostia also supplied Rome with corn from Sicily and Sardinia. It was not, however, till the wars with Carthage rendered it of importance as a naval station that it appears in history. From Ostia Claudius sailed on his expedition to Britain, and it was a favorite resort of the Emperor Nero.

The decline of Ostia appears to have been due to the constant filling up of the river, from which its site is now two or three miles distant. Claudius constructed a new harbor with great labor about two miles north of Ostia, which communicated with it by a canal. It was called the Portus Augusti, and afterward, when enlarged by Trajan, the Portus Trajani. The new port became the seat of a town called Portus Ostiensis or simply Portus. It communicated directly with Rome, and soon began to encroach on the trade of Ostia, which, however, continued to flourish until its destruction by the Saracens in the 9th century. Its ruins are about half a mile below the modern village, founded by Gregory IV in 830, and strongly fortified, which is now a place with about 1,000 inhabitants. The ruins of Portus are on the right bank of the Fiumicino, about two miles from the coast.

Modern excavations at both places have revealed a number of interesting remains of ancient public buildings, temples, shrines and tombs. An electric tramway connects with Rome. Consult the article on the excavations by Professor Dante Vaglieri in the *Cosmopolitan Magazine* for March 1912.

OSTIAKS, ös-ti-äks', a primitive Finnish race who dwell in the Siberian governments of Tobolsk and Tomsk. They consist of three tribes, distinguished from each other by customs and language and live almost exclusively by fishing. Their language, of which the dialects are numerous, is classed as a branch of the Samoeidic, a language of Turanian stock. At present their aggregate amount may be estimated at 30,000. Christianity has made some headway among them, but the old superstitions have been fused with it. Of uncertain origin, though possibly Mongolian stock, are the Siberian Yenisei Ostiaks, on the Yenisei, between the Upper and Lower Tunguska. They speak an entirely different language from all the other Ostiaks, and for a long period have completely adopted Mongolian customs.

OSTIARIUS (door-tender), one of the four minor orders in the Catholic Church, the other three being lector, exorcist and acolyte. It is definitely mentioned as early as 251, and the form of ordination, with the symbolic delivery of the church keys, was fixed before the 6th century. The duties are those commonly associated with the sacristan. The four minor orders are now usually conferred on the same day, being preceded perhaps by a year by the ceremony of conferring the tonsure and followed by the separate ordinations to the subdiaconate, diaconate and priesthood.

OSTRACISM (Gr. *ostrakon*, shell), an ancient mode of judgment by which, according to the Athenian law, a citizen was consigned to banishment. It was not a punishment for any

offense actually committed, but a precaution against the projects of personal ambition and the excessive growth of individual power and influence. When it was decided by the popular assembly and senate that a citizen should be banished, no name being mentioned in the preliminary discussion, the voting took place in the following manner: A place in the *agora* was enclosed by barriers, with 10 gates for the 10 tribes. By these the voters entered and deposited their votes, written on a shell or piece of tile. The archons counted the votes, and the person against whom the plurality was given, provided there were more than 6,000 votes, was obliged to leave the city within 10 days. The period of banishment was usually 10 years. Ostracism did not include forfeiture of property and was not considered a disgrace. Among the distinguished persons ostracized were Themistocles, Aristides and Cimon, son of Miltiades. Similar methods of procedure existed in Argos, Megara, Miletus and Syracuse. Ostracism seems to have been introduced to Athens by Cleisthenes (q.v.) in 510 B.C., but not to have been used until it was employed against Hipparchus in 488-487 B.C. Consult the various histories of Greece and Busolt, G., 'Die Griechische Staats- und Rechtsaltertümer' (2d ed., Munich 1892); Gilbert, 'The Constitutional Antiquities of Athens and Sparta' (tr., London 1895).

OSTRACODA, an order of *Entomostraca* or small *Crustacea* (qq.v.), in which the body is unsegmented and completely enclosed in a bivalve shell or carapace. The shell is attached to the body only on the dorsal side, where there is an elastic divaricating ligament whose action is opposed by an adductor muscle. When the valves are opened seven pairs of appendages are exposed. These are two pairs of antennæ, a pair of stout chewing mandibles, two pairs of maxillæ and two pairs of locomotory legs. All of these appendages except the mandibles are more or less concerned with swimming and creeping. Besides tactile organs there is a median eye and sometimes a pair of eyes. The sexes are always separate. Sometimes the eggs are carried within the female's shell, but usually are deposited on water plants. The young pass through a nauplius stage with three pairs of appendages, but are peculiar in the presence of a bivalve shell. Numerous species inhabit both fresh and salt waters and many are known in the fossil state, being first found in the Cambrian strata, reaching their zenith in Ordovician times, and assuming their modern forms in the Cretaceous. The most frequent are the species of the fresh-water genus *Cypris* (q.v.), lively little animals found in great numbers in ponds and aquaria. *Cypridina* is marine, and has the shell excavated in front to permit the passage of the very prominent antennæ. It has both paired and median eyes and a large heart. Consult Packard, 'Zoology' (1897); 'Cambridge Natural History' (Vol. IV, London 1909).

OSTRACODERMI, a suborder of plecognath fishes, according to the classification of Jordan (see *ICHTHYOLOGY*), composed of the trunk-fishes, puffers, porcupine-fishes and their allies, which have the body "inclosed in a three-, four- or five-angled box or carabace, formed by polygonal bony scutes, firmly jointed at their edges," and are without a spinous dorsal fin.

This term has also been used as a synonym of *Ostracophori* (see *OSTRACOPHORES*).

OSTRACOPHORES, a subclass of small fishes (*Ostracophori* or *Ostracodermi*), composed of very early Palæozoic forms with persistent notochord and endoskeleton not calcified; mandibles and true paired fins are apparently absent. The exoskeleton was well developed and the head and anterior portion of the trunk was usually covered with plates, which in many form solid and extensive shields, making the fish look much like a horse-shoe crab; indeed the remains of many were at first mistaken for those of crustaceans, arachnids or even gigantic beetles. The mimicry of the contemporary eurypterids (see *EURYPTERUS*) was very close. Louis Agassiz first recognized them as fishes. None of these fossils exhibit the slightest trace of ordinary jaws, or of a segmented axial skeleton in the trunk, or arches for the support of paired limbs. The dermal armor is remarkable for the extent to which vascular spaces are developed in its middle layer; in the oldest and simplest forms no bone-cells have been found in any part of the armor. There is always a shield covering the top of the head, and usually another over the abdominal region; and opposed to the latter is a ventral armature which meets the dorsal plate at each side in an open suture. The tail seems always to have been flexible, though scaly in some species. The mouth, according to Woodward, must have been on the ventral side, with the nasal sac or sacs just in front of it. The gill-pouches opened outwardly into a covered space communicating with the exterior by a posterior orifice. Eyes are distinct, and other cephalic organs, as ears, and a pineal eye may be inferred from impressions in the interior of the head-plates. Traquair regards certain discoveries as showing some close relationship between ostracoderms and primitive sharks. Gaskell and Patten, in very different ways, consider the ostracophores as stages in the development of the vertebrates (q.v.) from the eurypterids.

Four orders are recognized in the class. The oldest and simplest is the *Heterostraci*, represented by the family *Pteraspidae*, whose species occur in various parts of the world in formations from the later Silurian and early Devonian ages. The hard shield in these fishes, some of which were a foot in length, is formed of a few plates, well fused in the adult, each plate of which is unlike anything else in the *Chordata*, for it consists of three layers,—an inner or nacreous layer of lamellæ, a thicker middle layer of polygonal cancellæ and an outer layer of dentine. Dermal sense-organs are well developed and arranged in canals within the middle layer, opening externally by a double series of pores. *Pteraspis* and *Cyathaspis* are well-known genera. Associated with this group by Traquair and Zittel-Eastman on later information are the family *Cælolepidæ*, formerly considered sharks; and the more familiar *Psammosteidae*, which extend the range of the group into the Upper Devonian. A second order, *Anaspida*, consists of a few species ornamented outwardly with tubercles, but no armature of fused plates. The third order, *Aspidocephali*, or *Osteostraci*, consists of many forms found in the Upper Silurian and Lower Devonian, and especially in the Scotch Old Red Sandstone,

which have a broad solid head-shield, consisting of three layers, the outer or hard vaso-dentine; the body of these fishes were covered with quadrangular scales; they had no paired appendages, but moved by means of a small dorsal fin and the heterocercal tail. This group is one of those most studied by Hugh Miller, Murchison and other early geologists, and has been the object of special treatises by Huxley, Lankester, Brandt, etc. *Tremataspis* is a genus representing an allied family.

A fourth order, *Antiarcha*, contains that remarkable form *Pterichthys* and allied genera of the family *Asterolepidæ*. These were small fishes of robust form, the head and forward parts heavily armed with large tuberculated plates united into a solid buckler by lateral plates. The hinder part of the body, small fleshy dorsal fin, set near the tail and the heterocercal tail itself are covered with small scales, except in the finny portions. The most extraordinary feature in this curious primitive fish were the paddle-like appendages, closely resembling in shape and action the flippers of a marine turtle, which were articulated by a complex joint just behind and beneath the corners of the mouth and were completely armored. They formed swimming organs analogous, but not homologous with the pectoral fins of later fishes. These and their allies, *Asterolepis*, *Bothriolepis*, etc., are found in the Devonian rocks of both Europe and North America. Consult Gaskell, W. H., 'The Origin of the Vertebrates' (1908); Patten, W., 'The Evolution of the Vertebrates and their Kin' (1912); Woodward, 'Vertebrate Paleontology' (1898); Zittel-Eastman, 'Textbook of Paleontology' (Part II, 1902); Traquair, 'Fossil Fishes . . . in the Silurian Rocks of the South of Scotland' (1899). See ICHTHYOLOGY.

OSTRICH, a great African running-bird (*Struthio camelus*). The ostriches constitute a genus (*Struthio*) and a family (*Struthionidæ*), of the group *Ratitæ* (q.v.), characterized by having but two toes, the third and fourth, of which the former is much the larger and bears a short hoof-like nail; an almost equally unique internal feature is the symphysis of the pubic bones. The ostrich is by far the largest of existing birds, attaining a height of seven to eight feet and a weight of 300 pounds, and was exceeded by only a few more or less closely related extinct ones. There are no true down feathers, but the contour-feathers are soft and lax, with free barbs and no aftershaft and are distributed uniformly over the skin without any arrangement into pteryx and apteria. On the body the plumage is black or blackish, with the quill plumes of the wings and tail white; the head and neck are nearly, and the legs quite, naked. The head is remarkably small for a bird, the eyes large and the beak flat; the horny covering of the latter is peculiar in being composed of several pieces separated by soft skin, instead of being continuous as in most birds. The gape is straight and reaches to a point beneath the eye. The absence of functional wings and tail, the elevated back, the stout, column-like legs with padded toes, the long, erect, curved neck and the great size, all combine to produce a very unbird-like aspect and to give a peculiar appropriateness to the name "camel-bird," applied to the ostrich by old writers.

Formerly the ostrich was abundant throughout Africa and a great part of the southern half of Asia. In the latter region it is now restricted to a few of the more inaccessible deserts, and in Africa is no longer found in the wild state, in Egypt or near the northern and southern settlements, but is still abundant throughout the intervening territory wherever sufficiently extensive and solitary wastes exist. Some zoologists consider that but a single species ranges over this whole vast territory; others—and this is the prevailing opinion at present—have distinguished three: *Struthio camelus* of northern Africa, *S. australis* of southern Africa and *S. molybdophanes* of Somaliland. In the first the naked parts of the skin are pink, in the second bluish and in the last lead-colored; the eggs of the first have a surface of ivory-like smoothness, in the other two they are pitted. Wherever abundant, ostriches live on the plains in association with zebras, hartebeestes, gnus, etc. Like these animals they are extremely alert and wary as well as timid. So fleet are they that even the Arab on his blooded steed can seldom overtake one single-handed, and even when hunted in relays, as the birds circle about their favorite territory, one or more horses are frequently sacrificed to the chase. When in full flight a full-grown ostrich is said to cover 25 feet at a stride. They are also captured for the sake of their plumes by means of pitfalls, shooting with poisoned arrows and in other ways. During the breeding season they form family parties consisting of one male and several females. The latter deposit their eggs to the total number of 50 or 60 in a shallow depression surrounded by a slight rampart of earth. Many of the eggs are broken, some of them to be devoured by the male, others to supply soft food to the young, so that the brood of young seldom exceeds 20 or 30, many of which fall a prey to carnivorous animals. The male exclusively incubates at night, while during the day the females take turns in guarding the nest or incubating the eggs. During the breeding season the male protects his family faithfully and if driven to extremities fights viciously, kicking sideways or directly forward so powerfully that men and even horses are reported to have been killed by the blows. Although herbage is their chief food, everything edible is eaten, and their habit of swallowing every kind of hard object, just as other birds do gravel, to complete the grinding apparatus of the gizzard, has given to the digestive capacities of the ostrich a wholly undeserved notoriety. They are very fond of water and bathe when opportunities offer.

Domestication of the Ostrich.—Although the flesh is but little used, the eggs of the ostrich are much esteemed for food by native Africans, and their shells serve a useful purpose in the construction of vessels and implements. But it is their plumes which have given a mercantile value to ostriches from ancient times till now. To furnish a ready supply as the wild birds became scarcer in accessible regions, domestication has been resorted to. This is said to have been practised by native tribes for many years, and about the middle of the last century was begun by the French in Algiers and the English in Cape Colony. In the latter place there are said to be now upward of 300,000 domesticated ostriches, yielding an an-

nual revenue of \$5,000,000. Ostrich farming in the United States is still in its infancy, but promises to become an important industry. The first experimental importation of ostriches was made into California in 1882, and at the present time about 1,500 of these birds are to be found on the pioneer ostrich ranches of California, Arizona, Texas and Florida. Large, level, grassy fields are enclosed by strong high fences, to form corrals in which the general flock runs. The breeding birds are separated in pairs or sets of one cock and two hens in smaller pens. A single pair will sometimes produce as many as 35 young, the average loss of which is as low as 10 per cent in California, but much higher in Arizona. By the removal of the eggs as soon as laid and rearing them in incubators the output is much increased. In Africa a single trio of birds has been known to produce 188 eggs, from which 133 young were raised in a single year. The chief sources of loss are injuries by the parent birds, cold, dry food, and in Africa an infectious disease. The newly hatched young are the size of a full-grown barnyard hen, and when well fed increase in height so rapidly that by the end of six months they nearly equal their parents. At first they are sheltered at night in brooding boxes, but are turned loose during the day to feed on green alfalfa or other succulent plants, which are, with an abundance of water, their nearly exclusive diet. Dry food is very likely to cause fatal digestive disturbances in the young. The old birds require but little care and are fed on any vegetable matter, but principally upon chopped beets, cabbage, oranges and corn. The plumes from the wings and tails of the fully grown birds are the most valuable and are cut or plucked once or twice a year, each bird yielding about \$50 worth annually on the American ranches, but very much more than that on the African farms. When the American stock has become thoroughly acclimated this industry will probably yield rich returns, as some of the South African farms are reputed to pay 40 per cent net profit on the investment. Experiments in ostrich breeding are being tried in Mexico, Central and South America.

Consult Mosenthal and Harting, 'Ostriches and Ostrich Farming' (1877); Martin, 'Home Life on an Ostrich Farm' (1891); Duncan, Report United States Department of Agriculture for 1888.

OSTRICH FERN, a genus (*Pteritis*) of ferns of the family *Polypodiaceæ*. The best-known species (*P. struthiopteris*), a native of Europe, has fertile fronds which resemble ostrich plumes; its sterile ones, which often attain a height of 10 feet, form a handsome vase-like mass of foliage. It may be readily propagated from offsets and is one of the most easily cultivated native ferns. *P. nodulosa*, the American species, is a similar plant.

OSTROGORSKI, ōs'trō-gō'skī, Moisei Ikovlevitch, Russian political scientist; b. Grodno, Russia, 1854. He was educated in Russia and in France and was elected member of the first Russian Duma. He made a close study of the American political system and in 1889 published articles on this subject in *Annales des Sciences Politiques*. He published later in French his authoritative and exhaustive work, 'La démocratie et l'organisation des partis poli-

tiques' (2 vols., 1903). Of this work Frederick Clarke published an English translation, to which James Bryce furnished a preface (2 vols., 1902; 2d ed., 1908). In 1910 the second volume appeared in slightly altered form under the title 'Democracy and the Party System in the United States.' He also wrote 'La femme au point de vue du droit public; Etude d'histoire et de législation comparée' (1892; English translation entitled 'The Rights of Women: A Comparative Study in History and Legislation' (1893).

OSTROGOTHS, ōs'trō-gōths, a people of the Gothic race who lived at a very early time in the region between the Don and the Dniester and the Black Sea and the headwaters of the Volga. They were conquered by the Huns 375 A.D. In 479 they under Theodoric crossed the Alps into Italy, which they completely conquered; in 552 they were themselves signally defeated and Italy became a part of the Byzantine Empire, the Ostrogoths as a separate nation then ceasing to exist. See GOTHS.

OSTROLENKA, ō'strō-lyēn'ka, Poland, district town on the Narev, 22 miles southwest of Łomża at the junction of the Lapy-Malkin and the Ostrolenka-Piljava railways. It was founded in 1427, was the scene of the victory (1807) of the French under Savary over the Russians, also of the victory (1831) of the Russians under Diebitsch over the Poles under Skrzynecki. During the recent World War this town changed from Russian to Teuton occupation several times. Its inhabitants in 1910 numbered 15,985, the majority being Jews.

OSTROVSKI, ōs-trōf'skē, Alexander Nikolayevitch, Russian dramatist; b. Moscow, 12 April 1823; d. on his Kostroma estate, 14 June 1886. He studied at the Moscow Gymnasium and University and, before obtaining his law diploma, was appointed registrar of the Commercial Court. Here he gained a close acquaintance with the local commercial world, its manners, traditions and viewpoints in their mediæval condition. And his plays relate chiefly to the conflicts, culture and education of this isolated Russian body of merchants. His first work (1847) was 'Scenes from the Life of Samoskvoretshi,' a Moscow city quarter. This was followed by his best comedy, 'We Can Settle with Our Own People.' He was a writer of considerable power and originality and added many perfect and vivid life types to the repertoire of Russian comedy. Others of his best works are 'The Poor Bride' (1852); 'Poverty is no Cause for Shame' (1854); 'A Lucrative Situation' (1857); 'The Storm' (1860), a drama; 'A Warm Heart' (1869). He did a clever translation of Shakespeare's 'The Taming of the Shrew' as well as several of the pieces of Cervantes. His collective works have been published in 10 volumes (Saint Petersburg 1885; 9th ed. with biography by A. Nos, Moscow, 1890; later ed., 1896). (See STORM, THE). Consult Patouillet, J., 'Ostrovski et son théâtre' (Paris 1912).

OSTWALD, ōst'valt, Wilhelm, German chemist; b. Riga, 2 Sept. 1853. He studied, from 1872, at Dorpat, becoming (1875) assistant in the physical institute of the university and teaching, from 1877, as privat-docent. He was made (1881) professor of the Riga Poly-

technikum and was appointed (1887) professor of physical chemistry at the Leipzig University. On the institution of the German-American exchange of professors he was the first (1905-06) appointed to Harvard. His first work was devoted chiefly to problems of chemical affinity, and he is considered the leader in modern chemico-physics. Of special importance is his research into electric conductivity of the organic acids, the parallelism between electrolytic dissociation of these acids and their powers of reaction. Other subjects investigated by him are the color of ions, catalysis, galvanic potential differences, etc. He has written 'Lehrbuch der allgemeinen Chemie' (Leipzig 1885-88; later ed., 1903); 'Grundriss der allgemeinen Chemie' (ib. 3d ed., 1899); 'Elektrochemie' (ib. 1894-95); 'Vorlesungen über Naturphilosophie' (ib. 1902; 3d ed., 1905); 'Conversations on Chemistry' (1905-06). He founded the 'Klassiker der exakten Wissenschaften,' a collection of reprints of the old treatises on fundamental laws (1889, 150 numbers). He also has published *Zeitschrift für physikalische Chemie* (Leipzig 1887), in collaboration with van't Hoff, and since 1901 *Annalen der Naturphilosophie* (ib.). Consult Walden, 'Wilhelm Oswald' (Leipzig 1904); Slosson, E. E., 'Major Prophets of Today' (Boston 1914).

OSUNA, ō-soo'nā, **Pedro Tellez y Giron**, DUKE OF, Spanish soldier: b. Valladolid, 1579; d. castle of Alameda, 1624. His caustic and satiric wit twice forced him to leave the Spanish court, to which he returned through the favor of the Duke of Lerma, after distinguishing himself in the Netherlands. He opposed the expulsion of the Moors, thus bringing upon himself the charge of religious infidelity. In Sicily, where he was viceroy (1611-15) and in Naples, where he held the same position (1616-20), he did much for the improvement of the common people, but was an enemy of the clergy in general and of the Inquisition in particular. He probably aimed to build up an Italian kingdom for himself, and in 1620 was recalled, arrested, subjected to a three years' secret trial and imprisoned in the castle of Alameda, where he poisoned himself.

OSWALD, ōz'wāld, **Saint**, king of Bernicia, in Northumbria, England, from 634 to his death, 5 Aug. 642. His father, Ethelfrith, had been one of the most powerful of the Saxon monarchs, but on his death the kingdom was overrun with invaders and Oswald, his son, was banished and took shelter among the Scots in Iona. Here he became converted to Christianity, which he resolved should be the religion of his kingdom. In 636 he recovered the throne of Northumbria and requested the monks of Iona to send missionaries for the conversion of his pagan subjects. In response Aidan came with a band of missionaries and established himself as bishop in the island of Lindisfarne. In a few years the whole north of England was converted to the faith. Meanwhile Penda, king of Mercia, was persecuting the Christians, and at length declared war on Northumberland. A battle took place at Maserfelth, and Oswald was slain. His severed head was recovered and carried to Lindisfarne, and that and other relics were finally deposited with Saint Cuthbert's coffin in Durham Cathedral. He was canonized as a

king and martyr, his festival being celebrated 5 August. Consult Churton, 'History of the Early English Church.'

OSWALD, Eleazer, American soldier and journalist: b. in England, 1755; d. New York, 30 Sept. 1795. He came to America in 1770 through sympathy with the patriot cause. In 1775, under Benedict Arnold, whose secretary he became, he served as captain at Ticonderoga and also at Quebec, where, Arnold being wounded, Oswald took command with great efficiency. In 1777 he rose to the rank of lieutenant-colonel. He engaged in the business of printing and publishing in Philadelphia and in New York, and politically was in violent opposition to Hamilton and the Federalists. He afterward entered the French army, in which, at the battle of Jemappes, he commanded an artillery regiment. The French government sent him on a secret mission to Ireland, after performing which he returned to New York.

OSWALD, Felix Leopold, American naturalist: b. Namur, Belgium, 6 Dec. 1845; d. 27 Sept. 1906. He was graduated from the University of Brussels in 1865 and studied later at Göttingen and Heidelberg. He became a physician; later abandoned the practice, came to the United States and devoted himself to natural history. He published 'Summer-Land Sketches' (1880); 'Physical Education' (1882); 'Days and Nights in the Tropics' (1887); 'The Bible of Nature'; 'Body and Mind'; 'Zoological Sketches'; etc.

OSWALD, Richard, British diplomat: b. Scotland, 1705; d. 1784. He spent several years in America and after his return to England engaged in mercantile pursuits in London. At the close of the War of the Revolution, Oswald, because of his especial knowledge of American conditions, was selected by the Earl of Shelburne as one of the English envoys to negotiate the Treaty of Paris. Oswald was very well disposed toward the new nation and even favored the cession of Canada to the United States. He also furnished bail to the amount of £50,000 for Henry Laurens.

OSWALD VON WOLKENSTEN, ōs'-valt fōn vōl'kēn-stīn, German poet: b. Gröden, 1377, of Tyrolese nobility; d. 2 Aug. 1445. His was a very active, irregular and adventurous life. Already at the age of 10 he was wandering over the world; he traveled over all Europe and the Orient as far as Persia and Arabia. From 1400 he was in his native land, engaged in fighting landowners and other feuds. He met great vicissitudes, spending some time in prison. He accompanied, from time to time, the campaigns, serving under Emperor Sigismund especially. His poems relate largely to these episodes and show many weaknesses, such as in metric construction, style, etc., but they are of a similar character to other 15th century productions. His poems were first published by Weber Innsbruck (1847). A large edition was brought out by Schatz and Koller in *Denkmälern der Tonkunst in Oesterreich* (Vienna 1902), later a smaller work by Schatz (Göttingen 1904). Schrott made translations (Stuttgart 1886). Consult Weber, B., 'Oswald von Wolkenstein und Friedrich mit der leeren Tasche' (Innsbruck 1850); Zingerle, 'Oswald von Wolkenstein' (Vienna 1870).

OSWEGATCHIE, ős-wę-gäch'í, Fort, a former French fortification near Ogdensburg, N. Y. It was also called Fort Présentation and Fort La Galette. In 1760 it was taken by the British and called Fort William Augustus.

OSWEGO, ős-wę'gō, Kan., city and county-seat of Labette County; on the Neosho River and the Missouri, Kansas and Texas and the Saint Louis and San Francisco railroads, 132 miles south-southeast of Topeka. The river furnishes excellent water power and there are a number of mills, including flour-mills. It is also the centre of a grain and livestock region, and there is some coal in the vicinity. A public library is maintained by the Library Association. Pop. 2,317.

OSWEGO, N. Y., city, port of entry, county-seat of Oswego County, on Lake Ontario at the mouth of the Oswego River and at the northern terminus of the State Barge Canal. It is on the Delaware, Lackawanna and Western, the New York, Ontario and Western and the New York Central and Hudson River railroads, about 35 miles north by west of Syracuse. Oswego was founded in 1724 as a trading post and military station. It was incorporated as a village in 1823 and in 1848 was chartered as a city. It was one of the most important places on Lake Ontario and in wars which took place along the northern frontier it was always considered a vantage ground and its possession was contested. In the French and Indian War and King George's War, Colonel Mercer built here two forts, strong for the times, 1755. In August 1756, the place was captured by General Montcalm, who destroyed the forts. This capture of Oswego was considered one of the important events of the French and Indian War. About 30 men on each side were killed or wounded and 1,690 of the British were taken prisoners. Oswego was made the centre of the military operations along the lake and, in the year 1759, General Amherst started from this place with a force of 10,000 men, for Quebec where Wolfe was in command. Oswego was the meeting place, in 1766, between Sir William Johnson and Pontiac, and at this meeting the latter submitted to the British. In the War of 1812 this place was again a disputed point. Its good harbor was always an attraction. On 6 May 1814 a British force attacked the place and captured it. After peace was restored, the place prospered and grew steadily as an important lake port and a shipping point for the products of the rich farms of the vicinity. When the West began to develop as a wheat country and the grain was at first sent East to be manufactured into flour, Oswego was one of the chief points of manufacture and reshipment. The grain elevators and flour-mills were then prominent features along the river and canal. The opening of the flour-milling industry in the West, near the wheat-fields, deprived the city of its great industry, from which loss it did not recover for years. The excellent water power was finally used for manufacturing other products and the city has now a large starch factory, machine-shops for oil-well supplies, boiler and engine works, knitting-mills, car-spring works, match and cigar factories, shade cloth mills, pump works, also manufactories of tools, glue, cose, gears and underwear and breweries. The

lake trade has increased and the city exports manufactured goods, farm products and fruit. The harbor, with its outer and inner haven, which can accommodate large steamers, has been so improved that the quantities of coal, lumber and grain brought here for reshipment can be handled with great rapidity. The exports total nearly \$4,000,000 yearly and the imports about \$1,500,000. The beautiful parks, the drives, especially near the lake and along the river, fine residences and grounds, all make an attractive city. Some of the places of interest are the old Fort Oswego (q.v.), the present Fort Ontario, which overlooks the harbor, the government building, the State arsenal, the court-house and city hall. Oswego is noted for its State normal and training school, founded by Edward Austen Sheldon. It has fine public and parish schools, a home for the destitute, two orphan asylums and the Gerrit Smith Library. The government is administered under a charter of 1896 which provides for a mayor, who holds office two years, and a council. The waterworks are owned and operated by the municipality. Pop. (1920) 23,626.

OSWEGO, a river in New York, formed by the junction of the Oneida and Seneca rivers in the northern part of Onondaga County and flowing north by west enters Lake Ontario at Oswego. It is 24 miles long and has a fall of 120 feet from its source to the lake. By means of a canal and locks, the river has been made navigable some distance from its mouth.

OSWEGO, Fort, the name of the fort built by the French about 1724, on the site of what is now the city of Oswego. Later Fort Ontario was built on the opposite (right) of the Oswego River. See **OSWEGO**.

OSWEGO BASS, the large-mouthed black bass. See **BASS**.

OSWEGO TEA, a name given to several species of labiate plants of the mint-like genus *Monarda*, particularly *M. fistulosa* and *M. didyma*, natives of North America, because of the occasional use of an infusion of the dried leaves as a beverage. The infusion is said to be useful in intermittents and as a stomachic. Some other species of *Monarda* are used in the same way and are not uncommonly cultivated in gardens for ornament, where they are sought by bees.

OSYMANDYAS, ős-í-măn'dī-as, Egyptian king, said by Greek writers to have reigned during the period between Menes and Moeris, and to have invaded Asia with a great army, penetrating as far as Bactriana. According to Diodorus, on his return he erected great works at Thebes, among which was a monument of unequalled magnificence, the Osymandeion, but this is supposed to be identical with the Rameseum on the west bank of the Nile at Thebes, built by Rameses II, with whom, however, there is much difficulty in identifying Osymandyas himself, whose exploits appear to be mostly of a fabulous character. Consult Diodorus, i, 47-49; Tzetzes, 'Chiliades,' iii, 892; iv, 620; Budge, 'A History of Egypt' (1902).

OTAGO, ô-tā'gō, New Zealand, a southern provincial district of South Island, bounded west, south and east by the Pacific, and on the

north by Canterbury and Westland. Area 25,487 square miles. Mountains rise in the west to 6,000 feet; the south and east are agricultural; the orchards in the central portion produce apricots, peaches and grapes. Gold is the principal mineral. The capital is Dunedin, other towns are Port Chalmers, Oamaru, Invercagill, etc. Otago was settled in 1848 by a body of Scotch Free Churchmen. Pop. (estimated 1916) 206,622. See *NEW ZEALAND*.

OTAHEITE, ô-tā-hē-tē or ô-tā'hē-tē, an island in the Pacific Ocean, now known as Tahiti. See *TAHITI*.

OTALGIA, earache; specifically neuralgia of the ear. Its attack is usually sudden, the pain coming on at once with full intensity. It is often associated with other ailments, of which it may be only a local symptom, and frequently arises from disorders of the teeth. Neuralgic pains in other parts of the face often follow it. When otalgia is very intense it extends to the temple and nerves on the same side of the face, in which it causes acute pains. It frequently departs suddenly and returns again generally to the same ear. The treatment when the disease is symptomatic must depend upon the cause. Ordinarily earache is due not to otalgia, but to otitis media, or inflammation of the middle or tympanic portion of the ear.

OTARU, ô-tā-roo, Japan, the chief town on the west coast of Hokkaido on the south shore of Ishikari Bay and connected by rail with Sappora and the coal region of Ishikari. There is a fine breakwater and sheltered harbor, and a marine experimental station. It has important herring and other fisheries and a large trade. Interesting archaeological remains have been found in the vicinity. Pop. 91,000.

OTAVALO, ô-tā-vā'lō, Ecuador, town, province of Imbabura, 25 miles northeast of Quito. It was settled in 1534; in 1868 it was completely destroyed by an earthquake and many of the inhabitants were killed. Since then it has been well rebuilt and has several mills manufacturing cotton and woolen goods. Pop. about 8,600.

OTCHAKOFF, ô-chā'kôf, Russia. See *OTCHAKOF*.

OTERO, Miguel Antonio, public official: b. Saint Louis, 17 Oct. 1859. He was educated at Saint Louis University and Notre Dame University, Indiana; and became city treasurer, Las Vegas 1883-84; clerk San Miguel County 1889-90; clerk of the United States District Court, 4th Judicial District of New Mexico 1890-93; governor of New Mexico 1897-1906; treasurer of New Mexico 1909-11; president board of penitentiary commissioners and parole board 1913-16. He was a delegate to the Republican National conventions 1892, 1900, 1904, 1908; chairman New Mexico delegation 1900, 1904; chairman New Mexico delegation Progressive National Convention 1912. He is officer or director in several large business enterprises.

OTERO, Rafael, Cuban dramatist: b. Havana, 1827; d. there, 1876. His first comedy was performed so early as 1842. Several others were afterward presented at Matanzas and Havana, among them *El Coburgo*, *'Del Agua*

Mansa, *'Mi Hijo el Francés* and *'Un Novia del Día*. He further wrote two works of fiction, *'La Perla de la Diaria*' (1866) and *'Cantos Sociales*' (1868). Much of what he wrote remains in the files of periodicals.

OTFRIED, ô'tfrēd, Alsatian theologian and poet: b. about 800; d. about 875. He was the author of one of the earliest specimens of composition in the German language. After having become a monk of the abbey of Weissenburg, in Alsace, he studied under Rabanus Maurus, abbot of Fulda. He then returned to his monastery, where he opened a school of literature and wrote a variety of works in prose and verse. The most important of these is a rhymed version or paraphrase of the Gospels in Old High German, still extant, in which there are some passages of lyrical poetry. He completed it about 868 and dedicated it to Ludwig, king of Germany. An edition of it was published by Piper in 1898 and modern German translations by Rapp (1858), Kelle (1870); and Pfeifferl, *'Otfried im Gewande seiner Zeit*' (1905).

OTHELLO, a tragedy by Shakespeare, which, although popularized by the acting of Richard Burbage, the greatest of Elizabethan actors, was not printed until 1622 in what is known as the first quarto. The text of this edition is some 150 lines shorter than that of the first folio (1623), which is the authoritative text. There is little external evidence as to the date of composition, but the internal evidence points to a date between *'Hamlet*' and *'King Lear*'—probably 1604. There is no better evidence of Shakespeare's power to transform crude material than the contrast between the clumsy story as given in Cinthio's *'Hecatomithi*' and the play itself. He humanized the characters, gave coherence to a very loose-jointed, rambling story and turned the almost absurd murder of Desdemona into one of the noblest concluding scenes in dramatic literature. The plot has the simplicity and symmetry of a classical drama, violating only the unity of place. The reason for the masterly plot is that it proceeds from the mind of Iago, whose brilliant intellect and masterful will dominate the play. He is, perhaps, the greatest impersonation of evil in Shakespeare's plays, if not in literature. His attempts to find some motives for his deeds were happily characterized by Coleridge as "the motive-hunting of a motiveless malignity." Complete master of his mind and will, cynical in his views of virtue and love, unscrupulous in his intrigues, he pursues his conquests until at last he is destroyed by a power he cannot understand. In striking contrast is Othello, a primitive, child-like, magnanimous man, who after a life of adventure and romance finds himself in a highly-civilized and somewhat decadent Italian life, whose subtle mind he cannot comprehend. His love for Desdemona, leading to the happy consummation of marriage, is as romantic as any of his hairbreadth escapes and "moving accidents by flood and field." When at last he is convinced of her infidelity he utters some of the most eloquent and some of the saddest words ever written by Shakespeare. His tragedy is due in part to the passion of jealousy, but it is not an ignoble jealousy, rather the

agony of being compelled to hate that which he supremely loves. Desdemona, "the sweetest innocent that e'er did lift up eye," suffers passively—like a dumb creature, tortured without cause by the being she adores. Her utter innocence and purity and her timid childlikeness represent the triumph of virtue over evil, but at the same time reveal the mystery of human suffering as goodness suffers vicariously in the struggle with evil. "The tragic loading of the bed" upon which she and the great warrior lie is a suggestion of the mystery which constitutes tragedy in the Shakespearian sense of that word. An interesting contrast is afforded in Browning's 'Luria,' in which the consolation of religion, and especially the hope of immortality, relieve the tragic intensity of the play.

EDWIN MIMS.

OTHMAN, öth-män, or **OSMAN I**, surnamed **GHAZI**, "the Victorious," Turkish sultan, founder of the Ottoman or Osmanli empire, which was named after him: b. Sukut, Bithynia, 1259; d. 1326. In 1288 he succeeded his father, Ertoghrlu, as chief of a Turkish horde in Phrygia, and in 1299, after successful campaigns which put the eastern part of Asia Minor in his hands, proclaimed his independence and took the title of sultan. Nicæa (1304), Marmora (1307) and Broussa (1326) came under his sway, and in his last years he made Karahissar his capital and issued a regular coinage. He was succeeded by his son Orkhan.

OTHMAN, or **OSMAN II**, sultan of the Turks: b. 4 Nov. 1605; d. Constantinople, 20 May 1622. The son of Ahmed I, in 1618 he came to the throne as 16th sultan and successor of his deposed uncle Mustapha I. He was defeated at Choczim (1621) by Sigismund III, king of Poland; attempted to suppress the Janizaries, but was captured by them and imprisoned. He was killed in prison by the grand vizier.

OTHMAN IBN AFFAN, third Moslem caliph: b. Mecca, about 565; d. Medina, 656. Mohammed's secretary and lieutenant, he married successively the prophet's two daughters, and in 644, after the death of Omar, was chosen caliph by the six appointed by Omar, of whom one actually wished Othman's election, each of the others pressing his own claims. Othman was then old and feeble, and not by nature over energetic in his prime, but he seems to have carried things with a high hand. He occupied Persia (645-647), eastern Africa and Nubia (651), began the spread of Islam in the islands of the Mediterranean, dared remove from their offices the tried generals of Abu Bekr and Omar to make room for his kinsmen and favorites, and raised a storm of disapproval by sitting in the very seat of Mohammed instead of two steps below it, like his two predecessors. He attempted to introduce a definitive revision of the Koran. A great plot, embracing all his early rivals and the sectaries who differed with him, was formed; the caliph having broken his promise to appoint new governors, was besieged and was assassinated by Abu Bekr at Medina. His rule, though disturbed at home, was the beginning of the imperial growth of Islam, thanks to the conquest of Cyprus, Armenia,

North Africa, etc. Consult Muir, Sir William, 'Annals of the Early Caliphate' (1883).

OTHO I, óthō (THE GREAT), founder of the Holy Roman Empire: b. 23 Nov. 912; d. 7 May 973. He was son of Henry I and was elected and crowned king of Germany at Aix-la-Chapelle in 936. His reign of 36 years was an almost uninterrupted succession of wars. After a 14 years' struggle he subdued Boleslav, duke of Bohemia; wrested the duchies of Swabia, Bavaria and Lorraine from the dukes of Bavaria and Franconia and gave them (in 949) to his sons Ludolf and Henry and to his son-in-law Conrad, count of Worms, respectively. He delivered the Italians from the oppressions of Berengar II, married the widow of Lothair, their first king, and was crowned king of Lombardy (951). In 955 he crushed the Hungarians on the Lechfeld. In 961 he was crowned king of Italy and in the next year emperor by Pope John XII. But shortly after John made an alliance with Adalbert, king of Upper Italy, to drive the Germans out. Otho the following summer marched against Rome, drove John out, deposed him and placed Leo VIII in the papal chair, though this proceeding is recognized as uncanonical and Leo is reckoned an anti-pope. The Byzantine court refused to acknowledge Otho's claim to the imperial dignity; but he defeated the Greek forces in Lower Italy, and the eastern emperor, John Zimisce, gave the Greek princess Theophania to Otho's son Otho in marriage. He was at once the greatest political and military power of the West, and he succeeded in putting an end to the divided allegiance of his clergy between throne and church.

OTHO II, called DER ROTE ("The Red"), Holy Roman Emperor: b. Rome, 955; d. there, 7 Dec. 983. He was the youngest son of Otho I. His elder brothers had all died before their father, who caused him to be crowned joint emperor (967), the first instance of the kind in German history. He assumed power in 973 and subdued the revolt of several powerful vassals, including his cousin, Henry II, duke of Bavaria. In Italy he suppressed a rising under Crescentius and then attempted to drive the Greeks from Lower Italy; but they called in the aid of the Saracens from Sicily and Otho suffered a total defeat near Cotrone, Calabria, 13 July 982 and with difficulty made his escape on a vessel. He died before fresh plans of conquest against Greeks and Arabians could be executed.

OTHO III, called MIRABILIA MUNDI ("Wonder of the World"), Holy Roman Emperor: b. July 980; d. 23 Jan. 1002. He was son of Otho II, and the last of the male branch of the Saxon imperial house. He was only three years old when he succeeded his father. In 996 he marched into Italy and crushed a fresh insurrection fomented by Crescentius. He was crowned emperor in 996 by Gregory V. He again crossed the Alps in 998 to suppress a second rebellion under Crescentius, whom he caused to be beheaded. On the death of Gregory, Otho raised his old tutor, Gerbert, to the pontificate as Sylvester II. Peace in Rome was, however, only temporary, and until his death Otho was mostly employed in quelling disturbances in various parts of Italy. Some historians

assert that his death was due to poisoning, an act of revenge on the part of the widow of Crescentius. The emperor was a strict religionist, much given to penances and pilgrimages.

OTHO IV, Holy Roman Emperor: b. 1182; d. 19 May 1218. He was the son of Henry, Duke of Saxony. He was educated at the court of his uncle, Richard I of England, was chosen by the Guelphs as rival king to Philip of Swabia in 1198, was recognized as sole king in 1208 and was crowned emperor at Rome, 4 Oct. 1209. However, the emphasis which he placed upon imperial sovereignty in Italy displeased the Pope, who excommunicated him in 1210 and in 1212 declared Frederick II the true king of Germany. He finally relinquished the struggle against Frederick and retired to his possessions in Brunswick.

OTHO, or OTTO, I, king of Greece, second son of King Louis of Bavaria: b. Salzburg, 1 June 1815; d. Bamberg, 26 July 1867. He was educated at the University of Munich, was nominated king of Greece by the London Conference 7 May 1832 and chosen to this office by the Greek National Assembly 8 August. Until 1 June 1835 he was guided by a regency. Upon coming to his majority he showed himself too weak, too easily influenced by his Bavarian courtiers, and, above all, too much under Russian control to win the confidence of the people. He was compelled to grant a constitution, the working of which was hampered by factional strife. Internal discord, financial difficulties and open breaks with Great Britain and France followed and 24 Oct. 1862 he was deposed by a provisional government and returned to Bamberg. The only work of any importance that he accomplished for Greece was the organization of a system of education; a stronger man in his place would probably have profited by the repeated opportunities given Greece to acquire some territory of Turkey. He was succeeded by Prince George of Denmark.

OTHO, Marcus Salvius, Roman emperor: b. 32 A.D.; d. 69 A.D. He was for a time governor of the province of Lusitania (Portugal) and joined Galba when the latter rebelled against Nero. On Galba's accession in 67 Otho became the royal favorite and was made consul; but when Galba appointed Piso as his successor, Otho, securing the allegiance of the Pretorian Guard, had Galba and Piso murdered and was proclaimed emperor in 69. The eastern provinces acknowledged him as emperor, but in Germany Vitellius was proclaimed by the legions of the lower Rhine. At first successful, dissensions broke out among his generals, the forces of Otho were finally overthrown by Vitellius at Berbriacum, in Italy, and the emperor killed himself after reigning three months and a few days. Consult Henderson, B. W., 'Civil War and Revolution in the Roman Empire, 69-70 A.D.' (1908).

OTHO OF FREISING, frī'zing, German chronicler of the Middle Ages: b. about 1114; d. Morimund, 21 Sept. 1158. He was the third son of the Margrave Leopold IV of Austria and Agnes, daughter of the Emperor Heinrich IV. In his 14th year he was made provost of the Institute of Kloster-Neuburg but studied at Paris. He entered (1130) the Order

of Cistercians at Morimund, Burgundy, became (1132) abbot of this monastery and (1137) then Bishop of Freising where he upheld the external conditions of the Church while he instituted successfully internal reforms. He was one of the earliest to introduce the Aristotelian philosophy into Germany. From 1147-49 he accompanied the unfortunate crusade of Conrad III. He brought out his so-called 'Chronicles' (1143-46) in eight books, treating the history from the philosophic side, under the title 'De duabus civitatibus,' with great purity of diction and grip on the material. More valuable as a useful source is his 'Gesta Friderici imperatoris' (continued to 1156) by him, then finished by Ragewin. This work was instigated by the emperor. His works were first published by Euspinian (Strassburg 1515), then by Wilmanns in *Monumenta Germaniae historica, Scriptores*, vol. 20 (special edition Hanover 1867), translated by Kohl (Leipzig 1894). Consult Hashagen, 'Otto von Freising als Geschichtsphilosoph und Kirchenpolitiker' (ib. 1900); Schmidlin, 'Die Geschichtsphilosophie und kirchenpolitische Weltanschauung Ottos von Freising' (Freiburg 1906).

OTHO OF NORDHEIM, nōrt'hīm, Duke of Bavaria: d. 11 Jan. 1083. He was a descendant of the powerful Saxon family of the counts of Nordheim. Agnes, widow of Henry III, gave Otho the duchy of Bavaria in 1061, in order to have his help in the fight which she foresaw would be waged against the claims of her son Henry IV to the empire. Otho, however, took sides with her enemies; Henry was seized in 1062 and Anne was deposed. This treachery of Otho was never forgotten by Henry IV, who in 1070 caused Otho to be accused of a conspiracy against the emperor. Otho in consequence was deprived of his duchy and forced to submit. He made several attempts to regain his territory and power and in 1077 secured the election of Rudolph of Swabia as German king. Otho remained in arms against Henry until his death. Consult Vogeler, Adolf, 'Otto von Nordheim' (Minden 1880).

OTIS, Bass, American artist: b. New England; 1784; d. 1861. He first came into public notice as a portrait painter in New York, and nothing is known about his previous years of study. In 1812 he settled in Philadelphia, where his only known genre picture, 'Interior of a Forge,' hangs in the Pennsylvania Academy of Fine Arts. His portraits include those of President Jefferson; Alexander Lawson; the painter Jarvis, and Dr. Physick, and one of himself. Some of his works he reproduced in mezzotint, and he is said to have produced the first lithograph in America.

OTIS, Elisha Graves, American inventor: b. Halifax, Vt., 3 Aug. 1811; d. Yonkers, N. Y., 8 April 1861. He worked on a farm; was a carriage maker 1838-45, and was head of manufacturing concerns in Albany, Bergen Heights, N. J., and Yonkers. His great invention, that of a safety device for an elevator so that it cannot fall even if the cable on which it is hung should break, was perfected for use in the last-named factory and probably did more to increase the value of city real estate by making tall buildings possible than any other invention

of the century. Otis also invented a special and independent engine for elevators, as well as a staple machine, a steam plow, a rotary oven and a safety bridge, which although without a draw does not impede navigation. The great elevator business begun by him was continued by his sons, Charles Rollin and Norton Prentiss Otis.

OTIS, Elwell Stephen, American soldier: b. Frederick, Md., 25 March 1838; d. 21 Oct. 1909. He was graduated at Rochester University in 1858 and at Harvard Law School in 1861; entered the Union army in 1862 as captain of the 140th New York Infantry and took part in many battles. Disabled for duty by a wound at Petersburg, 1 Oct. 1864, he was discharged from the volunteer service with brevet rank of brigadier in 1865; in 1866 became lieutenant-colonel of the 22d Infantry; served in the West 1867-85; in the campaign of 1876-77 reducing Sitting Bull to submission, and was organizer and head of the Leavenworth School of Infantry and Cavalry from 1881 to 1885. He commanded at Assiniboine, Mont., 1885-90; from 1890 to 1893 was superintendent of the recruiting service, his rank in the latter year being full brigadier; and, after commanding the departments of the Columbia (1894-97) and of the Colorado (1894-98) and the department of the Pacific (1898-99), was appointed commander of the United States forces in the Philippines and military governor. He was a member of the Philippine Commission 1899. In May 1900 he retired from the governorship of the Philippines; in June was promoted major-general, and in October became commander of the department of the Lakes, a post which he held until his retirement from active service in March 1902.

OTIS, Fessenden Nott, American surgeon: b. Ballston Spa, N. Y., 6 March 1825; d. New Orleans, 24 May 1900. He was graduated from the New York Medical College in 1852; was surgeon of the New York police department in 1861; lecturer on genito-urinary diseases at the New York College of Physicians and Surgeons 1862-71 and clinical professor there from 1871 to 1890. Among surgical instruments invented by him may be cited the urethrometer and the dilating catheter. He was the author, among other works, of 'Urethral Strictures' (1877); 'Genito-Urinary Diseases' (1883).

OTIS, George Alexander, American surgeon: b. Boston, 12 Nov. 1830; d. Washington, D. C., 23 Feb. 1881. He was graduated (1849) at Princeton and (1851) at the medical department of University of Pennsylvania, continuing his studies in London and Paris. He settled (1852) at Richmond, Va., but moved (1854) to Springfield, Mass. At the outbreak of the Civil War he was appointed surgeon of the 27th Massachusetts Volunteers and was mustered in in 1861. Serving throughout the war he received four brevets for distinguished service. In 1864 he was made curator of the Army Medical Museum and placed in charge of the division of surgical records. Among other works he wrote 'Surgical History of the War of the Rebellion' (unfinished). For some years he edited the *Virginia Medical and Surgical Record* and remained a regular contributor

thereafter. In 1880 he was promoted to the rank of major and surgeon in the regular army.

OTIS, Harrison Gray, American orator and statesman, nephew of James Otis (q.v.): b. Boston, Mass., 8 Oct. 1765; d. there, 28 Oct. 1848. He was graduated from Harvard in 1783, studied law and was admitted to the bar in 1786. He was a member of the Federalist party in Congress, 1797-1801, and United States senator, 1817-22. He had previously sat in the Massachusetts legislature, and he took an active part in the Hartford Convention of 1814, and was mayor of Boston in 1829. In the Senate he opposed the extension of slave-holding territory. His published works include 'Letters in Defense of the Hartford Convention' (Boston 1824) and 'Orations and Addresses.' Consult Loring, J. S., 'The Hundred Boston Orators' (Boston 1854).

OTIS, Harrison Gray, American soldier and journalist: b. near Marietta, Ohio, 10 Feb. 1837; d. 30 July 1917. He was apprenticed to a printer at 14 and had a few months' education at Lowell, Ohio (1856-57), but was graduated (1857), after a commercial course, at Granger's College, Columbus. In 1860, while residing at Louisville, Ky., he was sent as delegate to the Chicago Republican National Convention that nominated Lincoln for President. Serving throughout the Civil War he rose to lieutenant-colonel of volunteers by brevet, and was present in the western Virginia field (1861), and from Bull Run bridge to Antietam (1862). After his discharge he published a small paper at Marietta, became official reporter of the House at the 1866-67 session of the Ohio legislature, then served (1867-70) in the government printing office at Washington. In 1876 he moved to Santa Barbara, Cal., where he conducted the *Press*, and in 1882 he became identified with the *Los Angeles Daily Times*, acquiring control by 1886. Offering his services on the outbreak of the war with Spain he was commissioned brigadier-general of volunteers (1898) and served in the Philippines and later during the Filipino insurrection. His brigade captured (1899) Caloocan. In his conduct of the *Los Angeles Times* he relentlessly opposed union labor, for which action the *Times* building was dynamited (1910) and 21 employees killed. In 1911 the McNamara brothers confessed their participation in the crime, thereby placing the act clearly on the shoulders of the labor union and creating a prolonged legal prosecution of the greatest public interest.

OTIS, James, American Revolutionary statesman: b. West Barnstable, Mass., 5 Feb. 1725; d. Andover, Mass., 23 May 1783. He was graduated from Harvard in 1743, studied law in the office of Jeremiah Gridley at Boston, was admitted to the bar at Plymouth, but after two years of practice there settled in 1748 in Boston, where he quickly attained eminence in the courts. During his rise in the law, he found an avocation in the study of the classical and English literatures, and published 'The Rudiments of Latin Prosody' (1760), a work of careful scholarship. He was appointed attorney-general, but this post he resigned rather than support the writs of assistance, application for which had been made in the Massachusetts Supreme Court. These writs were

warrants permitting general search for smuggled goods, and Otis was entirely convinced of their illegality. In February 1761 the matter came to debate before the court. Gridley appeared for the crown and Otis and Oxenbridge Thacher, another well-known lawyer, for the opposition. Otis' speech, occupying some four or five hours and marked by an argument of great learning and intellectual force, has been called the prologue of the Revolution. John Adams, whose notes taken in the court-room and later revised are the only authority for the content of this great effort, declares that "then and there was the first scene of the first act of opposition to the arbitrary claims of Great Britain." Decision was reserved; and though some writs were granted, none was ever enforced. In 1761 Otis was elected to the legislature, where he gained a high reputation for his eloquence and patriotic earnestness. From this time until 1769 he was the pre-eminent leader of thought in that discussion and development of opinion which preceded the war. In 1762 he published 'A Vindication of the Conduct of the House of Representatives of the Province of Massachusetts Bay,' a brochure of "exasperating candor," of which John Adams said: "How many volumes are concentrated in this little fugitive pamphlet . . . !" This is regarded as a chief source for subsequent arguments against Parliamentary taxation and in favor of free speech. It was followed by two others, 'The Rights of the British Colonies Asserted and Proved' (1764), which maintained a conciliatory tone and was therefore displeasing to the extremists, and 'Considerations on Behalf of the Colonies' (1765), increasingly bitter, and satisfactory to his previous critics. Otis was a prominent member of the Stamp Act congress, which met at New York in October 1765; in 1766 was elected speaker of the general court, but did not assume office because of the negative of the governor. In 1768, after Townshend's bill for the taxation of the colonies had been passed by Parliament, the general court despatched to the remaining colonies a second circular-letter, urging unity in some plan toward common protection. This letter was drafted by Otis and corrected by Samuel Adams. Bernard, royal governor, demanded the recall of the letter as traitorous, and Otis made a speech, advocating non-compliance, which the Royalists thought might be the "most violent, insolent, abusive and treasonable declaration" ever uttered. But the legislature did not vote for the recall of the circular. Otis was now wholly occupied with public interests, writing for the press and addressing political gatherings. In 1769 he was accused in England of treason by the customs commissioners, and replied by a denunciation of the commissioners in the *Boston Gazette*. He thus became involved in a quarrel with Robinson, one of the commissioners, during which he received a wound of the head which is supposed to have brought about his subsequent insanity. He was awarded £2,000 damages, but refused to claim the sum upon receipt of a written apology. During the rest of his life he was subject to fits of aberration, and though he was in the legislature in 1771 and for a brief time resumed his Boston practice, he continued in general unequal to public and professional duties. While in an unbalanced

condition he took part in the battle of Bunker Hill. He was killed by a flash of lightning. More than any other American Otis gave the impetus and direction to the struggle for independence. Consult the biographies by Knapp in 'Sketches of Eminent Lawyers, Statesmen and Men of Letters' (1821) and Tudor (Boston 1823); also Tyler, M. C., 'Literary History of the American Revolution' (New York 1897); and the 'Life' by F. Bowen (Boston 1847).

OTITIS, or **OTITIS MEDIA**, inflammation of the tympanic cavity of the ear. It may be either acute or chronic; and may come on during the course of certain febrile affections, especially scarlatina, or in consequence of a scrofulous, rheumatic or gouty constitution; or it may be excited by direct causes, as exposure to currents of cold air, violent syringing or probing, etc. The acute form is usually ushered in with sudden pains, coughing and buzzing noises, and by increased deafness. Unless prompt relief measures are taken, suppuration follows, and the membrane of the tympanum becomes ulcerated and pus discharges follow, or inflammation of the dura mater and abscesses in the brain may be established. In less severe cases there is usually considerable persistent damage, and an obstinate discharge of matter is a frequent sequence of the disease. The treatment of so serious an affection must be left solely in the hands of the medical practitioner. The symptoms of the chronic and less acute varieties of otitis are unfortunately so slight, that they are often neglected, until the patient finds the sense of hearing in one or both ears almost completely gone. In these milder forms, the general treatment is to combat the diathesis on which they frequently depend, and to improve the general health. Small blisters occasionally applied to the nape of the neck or to the mastoid process are often of service in very chronic cases. If there is any discharge, the ear should be gently syringed once or twice a day with warm water, after which a tepid solution of sulphate of zinc (one grain to an ounce of water) may be dropped into the meatus and allowed to remain there two or three minutes.

OTO, *ō'tō*, an Indian tribe of North America of Siouan stock. They dwelt formerly in eastern Nebraska, south of the Platte River. The remnants of the tribe, numbering about 400, now share a reservation in Oklahoma with the Missouri, with whom they have a common language.

OTOCYON. See CAPE FOX.

OTOLITH. See ANATOMY; EAR.

OTOMACO, *ō'tō-mā'kō*, a South American Indian tribe, dwelling in the Orinoco forests of central Venezuela. They are very savage and represent a very low state of Indian culture. No adequate study of them has yet been made, but it is supposed that they constitute a separate linguistic stock. Consult Chamberlain, A. F. (in *Journal de la Société des Américanistes de Paris*, New Series, Vol. VII, Paris 1910); and Tavera-Acosta, 'En el Sur' (Ciudad Bolívar 1907).

OTOMI, *ō-tō'mē*, or **OTHOMIS** (Nahuatl *otomil*, wanderer), one of the most ancient and most widely scattered Indian tribes in Mexico. Previous to the appearance of the

Toltecs, by whom they were driven to the mountainous regions of the country, they were settled in the valley of Mexico. On the decline of the Toltec power they returned, but were afterward dislodged by the Aztecs. At a later period part of their territory was regained. They became partially civilized before the appearance of the Spaniards by whom they were conquered. Some of the bands accepted Christianity. They occupy the mountainous portions of the states of Querétaro, Hidalgo and Guanajuato, and numerous bands are found in several other portions of the country. Their language is one of the most unpleasant of all Indian dialects, but many of the people converse in Spanish, and have become Mexican citizens. A grammar and dictionary was published in 1767, and several small religious works in the native tongue have been issued.

OTRANTO, Strait of, passage between the Adriatic and Ionian seas, separating the southernmost part of Italy from Albania. Its minimum width is 45 miles between Cape Glossa, Albania, and Otranto, Italy.

OTSEGO, ōt-sē'gō, a lake in Otsego County, N. Y., the main source of the Susquehanna River. It is a beautiful body of water; along its shores are many attractive cottages, but it is noted chiefly for its connection with James Fenimore Cooper (q.v.). Cooperstown (q.v.) is on the south shore.

OTSEGO BASS. See WHITEFISHES.

OTTAR OF ROSES. See ATTAR OF ROSES.

OTTAWA, ōt'a-wā, Canada, city, capital of the Dominion of Canada and of Carleton County, in the province of Ontario, at the confluence of the Ottawa and Rideau rivers, and on the Canadian Pacific, Canada Atlantic (Grand Trunk), Canadian Northern, and New York and Ottawa (New York Central) railroads, about 120 miles west of Montreal. The Chaudiere Falls, in the Ottawa River, are 600 feet wide and 40 feet high. A road bridge spans the river immediately below the falls, while the Canadian Pacific Railroad bridge crosses some distance above, and a large combined railway and road bridge an equal distance below. The Rideau Falls, so called by the early French explorers because of its curtain-like appearance, carry the waters of the Rideau River into the Ottawa, toward the eastern end of the city. These falls, as well as the Chaudiere, supply extensive water power. A careful estimate places the available water power in the immediate neighborhood of Ottawa at 200,000 horse power, while within a radius of 45 miles there is a total of 1,000,000 horse power. Ten bridges cross the Rideau River within the city limits. A beautiful driveway has been designed which is to engirdle the city, 30 miles of which have been constructed. The Ottawa River and its tributary, the Gatineau, are the routes by which timber is brought down to Ottawa from the great northern limits.

Industries, etc.—Around the Chaudiere are a number of large industries, for the most part connected with the cutting and manufacture of lumber. The cut of timber in the Ottawa Valley has been nearly 700,000,000 cubic feet in one year, and almost every foot was prepared for market in the Ottawa and Hull

lumber mills. Besides the lumber industry proper, there are large mills and factories, both on the Ottawa side and in the neighboring city of Hull, for the manufacture of matches, indurated fibre ware, wooden ware, pulp and paper, as well as flour mills, tanneries, brick and tile works, foundries, machine-shops, railroad car and repair shops, furniture factories, carriage works. There are some 180 factories, employing 17,000 hands. Ottawa is the centre of a good farming district, and within a few miles of the city, on the Quebec side of the river, are extensive mineral deposits, iron, asbestos, phosphate of lime, mica, zinc, plumbago. Electric railways cover every section of the city, and extend out of town east to Rockcliffe Park, and west to Britannia-on-the-Bay, on the south side of the Ottawa, and Victoria Park, on the north or Quebec side.

Principal Buildings.—The Parliament and government buildings, situated on Parliament Hill, 125 feet above the river, and covering about four acres of land, are built in the Italian Gothic style, of Canadian sandstone quarried in the Ottawa Valley, and Devonian sandstone from Potsdam, N. Y. The foundation-stone was laid by the Prince of Wales (later King Edward VII) in 1860. The original buildings, including the Victoria Tower, 180 feet high, and the library, cost about \$8,000,000. The Parliament building was (with the exception of the library) destroyed by fire 3 Feb. 1916, and is now (1918) in course of reconstruction. The growth of the country in recent years has necessitated the building of a fourth large building, known as the Langevin Block, facing the Houses of Parliament, but outside the grounds, and since its completion, government business has increased so rapidly that many large buildings have had to be leased for departmental use, in various parts of the city. Other prominent buildings are Rideau Hall, the official residence of the governor-general, the post office, city hall, public library, banks, churches, colleges and schools. Important buildings erected within recent years include the Victoria Museum, which accommodates the Geological Museum and the National Art Gallery, and is the temporary meeting place of the Dominion Parliament; the Royal Mint, the Astronomical Observatory; the National Archives; the building devoted to the customs and state departments; and the Chateau Laurier, a magnificent hotel operated by the Grand Trunk Railway.

Churches, Educational Institutions, Libraries, etc.—There are two cathedrals, Church of England and Roman Catholic, as well as six hospitals, orphanages and homes for the aged and the friendless. Under the school laws of the province separate systems of schools are maintained for Protestants and Roman Catholics. The chief educational institutions are the University of Ottawa (Roman Catholic), the Provincial Normal School, affiliated with Toronto University, the Model School, Collegiate Institute, Ladies' College, Saint Joseph's College, and a number of special schools in charge of the Oblate Fathers, three theological schools, a number of private academies, and the public and separate schools. There are several libraries, chief of which is the Library of Parliament, which contains over 200,000 volumes,

besides some valuable manuscripts. Next to Toronto, Ottawa is the chief intellectual centre of the Dominion and is the headquarters of the Royal Society of Canada. Representatives from a number of foreign countries, including a United States consul-general, are stationed at Ottawa. The Pope is represented here by a special envoy. The head office of the Bank of Ottawa is here.

History, Government, etc.—Champlain gives us the first account of what is now the site of Ottawa, but it was not until the end of the 18th century that the first white settler, one Philemon Wright, a New Englander, cut a home for himself out of the woods on the Hull side of the river. Wright acquired property on the south side as well and transferred the site of the future capital to one Nicholas Sparks as payment for farm labor. Sparks reluctantly accepted the land. His descendants are now among the best-known and wealthiest families of Ottawa. In 1826 the British Government sent out Colonel By to survey and construct the Rideau Canal, to connect the Ottawa with the Saint Lawrence at Kingston. The engineers and laborers engaged upon the canal formed the nucleus of the future city, which was at first called Bytown. Sir John Franklin, returning home from one of his Arctic voyages, laid the corner-stone of the canal locks in 1827. In 1854 Bytown was incorporated as a city and the name changed to Ottawa. In 1858 Queen Victoria selected it as the capital of Canada, much to the disgust of the rival cities of Montreal, Quebec and Toronto. The first Dominion Parliament was held here in 1868. The government maintains a large experimental farm a mile or two southwest of the city. Hull (q.v.), across the river and in the province of Quebec, is one with Ottawa in commercial and industrial matters, but entirely separate in municipal government. The government of both cities is vested in a mayor and corporation. Pop. (1901) 59,928; (1911) 87,062; (1921) 107,137.

LAWRENCE J. BURFEE.

OTTAWA, Ill., city, county-seat of La Salle County, at the confluence of the Fox and Illinois rivers, on the Illinois and Michigan Canal, and the Chicago, Burlington and Quincy and the Chicago, Rock Island and Pacific railroads, about 80 miles southwest of Chicago. It was settled as farm land in the early part of the 19th century, but was not incorporated until 1837. It is in a productive agricultural region, in which are extensive deposits of fire-clay, glass-sand and bituminous coal. It has considerable manufacturing interests. The chief establishments are glass factories, potteries, agricultural implement shops, saddleries, carriage factories and organ and piano factories. It has a large trade in brick, tile, sewer pipe and other manufactures, and in farm and dairy products. Some of the prominent buildings are the Illinois Appellate Court building, the city and county buildings, the Ryburn Memorial Hospital and the church and school buildings. Its educational institutions are Pleasant View College, under the auspices of the Lutherans, Saint Francis Xavier Academy (Roman Catholic), public and parish schools, a high school library, and Reddick's public libraries. It has four beautiful parks. The city charter, in accordance

with the State law of 1871, provided for a mayor, who holds office two years, and a council; but now the government of the city is on the commission plan. The city owns and operates the waterworks. Pop. (1920) 10,816.

OTTAWA, Kan., city, county-seat of Franklin County, on Marais des Cygnes River, and on the Missouri Pacific, the Atchison, Topeka and Santa Fé, and the Southern Kansas railroads; about 40 miles southeast of Topeka. It is in a farming and dairy section. The place was named for the Ottawa Indians who emigrated from Ohio in 1833. The town was founded by John Tecumseh Jones, a Pottawatomie missionary, who taught the Ottawas. The Santa Fé Railroad shops, employing 400 men, are located here. It has flour mills, carriage works, creameries, grain elevators, brick and tile yards and a furniture factory. There is considerable trade in livestock, dairy products, nursery stock, grain, wool and fruit. It is an attractive, residential city, with well-kept streets and fine parks. It is noted for its moral tone and as being an educational centre. It is the seat of Ottawa University, a Baptist institution which had, in 1917, 388 students. It has the summer educational and social gathering called the Ottawa Chautauqua Assembly, the second (in point of time) "Chautauqua" in the United States. It has also a free public library. There are very many church edifices, and the place is often called "The City of Churches." The water system and electric-lighting plant are municipally owned. In 1913 the commission form of government was instituted. At least 90 per cent of the population are native-born white Americans. Pop. 9,018.

OTTAWA, Ohio, village, county-seat of Putnam County, on the Blanchard River, and on the Findlay, Fort Wayne and Western, the Cincinnati, Hamilton and Dayton, and the Detroit, Toledo and Ironton railroads, and the Ohio Electric road. It is about 90 miles northwest of Columbus. It is in a farming section, and has several industries connected with farm products and stock-raising. Its chief manufactures are flour, lumber and lumber products, clay products, beet sugar and dairy products. Pop. 2,167.

OTTAWA, a river of Canada, the chief affluent of the Saint Lawrence, forming for the main part of its course the boundary between the provinces of Quebec and Ontario. It rises on the high land which divides the basin of Hudson Bay from that of the Saint Lawrence, in lat. 48° 30' N., and for 300 miles, from its source to Lake Temiscamingue, runs from northeast to southwest. In portions of its course the river is very irregular in width, being lost in lakes through which it flows, while in others the waters contract to 40 or 50 yards and in many places forming beautiful cascades, fall over precipitous rocky ledges. Lake Temiscamingue is 67 miles long, and varies from a few hundred yards to nearly 10 miles wide. On leaving Lake Temiscamingue, the river, suddenly changing its direction, flows to the southeast for 400 miles, widening at its outlet into the expanse of water known as the Lake of Two Mountains and finally discharges into the Saint Lawrence at the Saint Ann's Rapids, above the island of Montreal. Calumet and Allumette islands, 75 and 95 miles respectively

above the city of Ottawa, belong to Quebec. Six miles above the city of Ottawa the rapids begin, which terminate in the Chaudière Falls, 40 feet high. The Ottawa is navigable from its junction with the Saint Lawrence to the falls, and is connected with Lake Ontario at Kingston by the Rideau Canal. The river is of considerable commercial importance, from the immense quantity of fine timber cut on its banks, and on those of its tributaries, the chief of which are the Gatineau, Madawasca, Coulogne and Lièvre. The Gatineau is 240 miles long, and the other tributaries mentioned vary in length from 130 to 205 miles. The drainage basin of the Ottawa and its tributaries is estimated at 86,000 square miles. The river was first explored by Samuel Champlain in 1613. Up to the early years of the 19th century it was the thoroughfare of explorers and fur traders from Montreal to the far West. The projected Georgian Bay Canal (440 miles long), which would halve the distance between Montreal and Sault Saint Marie, as compared with the Welland Canal route, would follow the Ottawa River the greater part of the way.

OTTAWA, University of, conducted by the Oblate Fathers of Mary Immaculate, was established in 1848 by the Rt. Rev. J. E. Guigues, O.M.I., D.D., at Ottawa, Canada. Under the presidency of the Very Rev. Father Tabaret, O.M.I., DD., the institution attained a high degree of prosperity. Originally incorporated under the title of "College of Bytown," this institution received, in 1866, the title of "College of Ottawa," together with the power of conferring university degrees. In 1883 its charter was so amended as to extend its original powers. The university received at the same time extensive powers of affiliation, in virtue of which, all the degrees conferred by the faculty are officially recognized in the Dominion and in all other British possessions. By a brief, dated 5 Feb. 1889, the Sovereign Pontiff, Leo XIII, raised the University of Ottawa to the rank of a Catholic university, with all the privileges conferred on such universities.

The program of studies includes (1) The theological course, which extends over four years. (2) The philosophical course which is both the crowning of the collegiate course and basis of all professional studies. Students may take their degrees both in sacred theology and philosophy. (3) The course of arts, which extends over four years, at the end of which the student may receive the diploma of bachelor of arts or bachelor of literature, after having passed the prescribed examinations. (4) The collegiate course, extending over three years and embracing all the matters necessary for matriculation. (5) The commercial course. The number of students attending all departments in 1916-17 was 700. These are recruited all over the Dominion, but largely from Ottawa and the surrounding district.

OTTAWA INDIANS, or OTTAWAS (from *adawe*, to trade, to buy and sell), an important American tribe of the Algonquian family formerly residing in the region of the Ottawa River in Canada, and when first met with by early French explorers, inhabiting the Manitoulin Islands and the northwest shore of the Michigan Peninsula. They comprised the Kiskakons, the Sinagos and the Keinouches.

They believed in a Great Creator whose eye was the sun by day, and the moon and stars by night, and who therefore could see all things everywhere, night and day, and from whom it would be impossible to hide any actions, either good or bad. They were governed by 21 precepts, or moral commandments, which bear a striking resemblance to the Decalogue. They also believed in certain deities who were governed by the Great Spirit over all, and who presided over various places as a country, mountain, river, lake or island; they were careful not to express anything which might displease such deities. Michabon, the "great hare," presided over the earth and created men from animals. Mirabichi was the "god of the waters." The Ottawas became the allies and friends of the French, and also of the Hurons, by which latter friendship they incurred the hatred of the Iroquois, and from whom, after the overthrow of the Hurons, they fled to the islands at the mouth of Green Bay, and thence to the country of the Sioux beyond the Mississippi. Becoming embroiled with the Sioux they were driven back, a band settling at Mackinaw, and afterward at Arbre Croche, and another band near Detroit. The Ottawas aided the French in their last war for Canada, but Pontiac (q.v.), chief of the Detroit Ottawas, would not surrender and organized a deep-laid conspiracy for the massacre of the English, in which, however, the Arbre Croche Ottawas would not join. About this time the tribe consisted of about 1,500 persons. During the Revolution and in the War of 1812 they were under British influence. They joined in treaties made in 1785 and 1789, but took arms with the Miamis soon after, again making peace in 1795, and a band about this time making a settlement on the Miami River. Numerous treaties ceding territory around Lake Michigan to the United States followed. A part went south of the Missouri in 1833, where they lost their identity. A band of Ottawas in Ohio, on 31 Aug. 1836, ceded 49,000 acres of land at Maumee, and 200 removed to 34,000 acres on the Osage, south of the Shawnees. Those remaining became scattered. The emigrants prospered for a while, but ill-advised building projects occasioned financial troubles, and, having asked for and obtained a reservation, by common consent they removed to Indian Territory in 1870. In 1836 the Michigan Ottawas ceded all their lands except reservations, and an option was granted them of taking up lands in severalty on these reservations by the treaty of 1855. They are mainly located in Michigan and there are a few in Oklahoma. In 1836 the Ottawas and Chippewas surrendered Manitoulin Island and the 23,000 islands in Georgian Bay to the British Crown. There are under 4,000 Ottawas in the United States and about 750 in Canada. Consult Blackbird, 'History of the Ottawa and Chippewa Indians of Michigan' (1887); and Hodge, 'Handbook of the Indians of Canada' (1913).

OTTAWA UNIVERSITY, founded in 1865 at Ottawa, Kan. It was incorporated under the joint control of the Baptists and the Ottawa Indians; the legislature set apart 20,000 acres from the Indians' reservation for the university, with the provision that two of the six trustees should be Indians. This arrangement did not prove entirely satisfactory, and in 1873 an adjustment was made that placed the

university entirely under the control of the Baptist denomination. There is a preparatory department, and in addition to the regular college instruction, there are courses in pedagogy and business. The college work is arranged in two courses, classical and scientific, leading to the two degrees of A.B. and B.S. All courses are open to women. The library in 1923 contained 10,000 volumes; the property held amounted to \$1,000,000, and the annual income was \$95,000. The students (1923) numbered 482, and the faculty 25.

OTTENDORFER, ô'tên-dôr-fër, Oswald, German-American journalist: b. Zwittau, Moravia, 26 Feb. 1826; d. 16 Dec. 1900. After studying law at Prague and Vienna he came to this country after the revolutionary disturbances of 1848, and, settling in New York in 1850, soon became editor of the *New Yorker Staats-Zeitung* and later (having married the lady who owned the property) its proprietor. Under his management it became the most influential German daily in America and after 1861 was independent in politics. He built and endowed an educational institution in his native town, founded a home for aged and poor men on Long Island and established the Ottendorfer Free Library in New York.

OTTER, SIR William Dillon, Canadian soldier: b. near Clinton, Ontario, 3 Dec. 1843. He received his education at Upper Canada College, Toronto; served for 22 years in the Queen's Own Rifles, active militia of Canada, and since 1883 permanent militia. He saw active service during the Fenian Raids of 1866 and 1870. In the North-West Rebellion of 1885, Otter was in command of the Battleford column; in the Boer War he commanded the first contingent from Canada. In 1905 he was made brigadier-general and major-general five years later. In 1910 he became inspector-general and chief military adviser to the Minister of Militia. He was knighted in 1913 and during the War of 1914-18 served as director of internment operations.

OTTER, a carnivorous mammal of the sub-family *Lutrinae* of the weasel family (*Mustelidae*). There are two genera, *Lutra*, including the true otters, and *Enhydris*, including the sea-otter (q.v.). The otters differ from the weasels chiefly in their webbed feet and aquatic life. The body is elongated and averages, exclusive of the tail, about two and one-half feet in length; the tail being somewhat tapering, but flattened, and serving as an efficient rudder to guide the swimming movements of the animal. The legs are short, but muscular, and exceedingly mobile; each foot possessing five webbed toes. The lips are whiskered; the ears short and the eyes large and prominent. The under fur is short, closely set, and woolly, and the outer coat of longer and coarser hairs, of dark-brown hue. In habits the otters are chiefly nocturnal animals, swimming about at night to prey on fishes, of which they are great destroyers, leaving many mangled after merely eating part of the flesh. They wander about a great deal in winter, going across the fields from stream to stream. The burrow is constructed near the waters' edge, the nest being situated at some depth in the bank of the river and lined with grass and leaves.

The American otter (*Lutra canadensis*)

averages about four feet in length, inclusive of the tail. The fur is of a lustrous brown color. It inhabits America generally, but is most plentiful in Canada, being rare on the Atlantic border of the United States. The Mackenzie River and other streams running into the Arctic Sea form noted haunts of the Canadian otter. It is chiefly noted for its fur, which is much valued commercially. A peculiar winter habit of this otter consists in numbers of these animals selecting a sloping bank of a river or a ridge of snow, and sliding down the sloping surface upon their bellies, the fore-legs being bent backward, while by means of the hind legs a swift forward impulse is given to the body. This sport (for such it really is) may be continued for a considerable time, the whole process reminding one of schoolboys similarly amusing themselves. These animals are caught in steel traps, which are set generally near the entrance to the burrow, and they have been exterminated in almost all the easily accessible streams of the country.

The European otter (*L. vulgaris*) inhabits Europe generally, and is a well-known denizen of Scotch rivers and streams. To the salmon it is particularly destructive, a pair of otters destroying an immense number of fish, and, as already remarked, leaving large numbers in a mangled condition after each meal. The pursuit of fishes is carried on with great dexterity by the otters, the lithe body accommodating itself quickly to all the turns and gyrations of the finny prey. This otter, although usually of an untamable and somewhat ferocious disposition, can occasionally be domesticated to a very perfect extent. A species (*L. nair*) is said to be tamed in India by fishermen and used for hunting fish; and in Great Britain tame otters have occasionally been kept for a similar purpose. The otter is still hunted for sport by means of dogs (see OTTER-HOUND) bred and trained to their work. When brought to bay the otter will defend itself with great pertinacity and will successfully meet any single dog of ordinary strength. When forced to the water the otter swims deftly and remains for very long periods concealed and swimming beneath the surface. On *Maigre* days the Roman Catholic Church permits the flesh of the otter to be eaten. It is said to be dark-colored, rank and of fishy taste. The fur is used, but not to any great extent. The sea-otter, *Enhydris*, is confined to the shores of the North Pacific. It is more aquatic than the species of *Lutra*, and has been found as much as 15 miles from land. Its tail is flattened as a paddle. It only walks with the greatest difficulty. The fur of the sea-otter is rare, silky and valuable. Consult Coues, 'Fur-bearing Animals' (1877); Stone and Cram, 'American Animals' (1902), and works on British and East Indian mammals.

OTTER, or ANCON SHEEP, a breed of sheep, which arose in Dover, Mass., in 1791, from a long-bodied ram which was deformed in that its legs were extremely short and bent outward, or bowed, like those of an otter. The progeny of this ram when mated with an ordinary ewe were often deformed like the sire, and for a long period the breed was easily maintained in that district, where it was esteemed because unable to jump over low walls and fences. This case is of great scientific

interest as an example of Mendelian dominance (see HEREDITY) in a sire and also as an example of how a sudden variation or sport may be perpetrated. It is also of interest to note that when, after a time, care was no longer taken to maintain the breed, on account of the introduction of the quiet merinos, it disappeared by crossing with ordinary sheep: the last typical specimen recorded died in 1813. Consult Humphreys, D., 'On a New Variety in the Breeds of Sheep' (*Philosophical Transactions of the Royal Society*, London 1813).

OTTER CREEK, a stream rising on the southern boundary of Rutland County, Vt., flows north-northwest through Rutland and Addison counties and empties into Lake Champlain near Ferrisburg. It is 90 miles long and is navigable for eight miles from its mouth. It supplies excellent water power to a number of towns, the most important of which are Vergennes, Middlebury and Rutland.

OTTER-HOUND, or **OTTER-DOG**, a large, rough-haired, powerful, hardy and courageous breed of hounds, cultivated especially in Great Britain to assist in otter-hunting. These dogs must be able to follow the game into the water and fight it in its retreats. A fair specimen will stand two feet tall and weighs 65 to 75 pounds. Consult Lee, 'Modern Dogs' (1897).

OTTER-SHREW, a very large South African aquatic shrew, which has a strange resemblance in appearance and habits to an otter. See POTAMOGALE.

OTTERBEIN, ȯt'tēr-bīn, Philip William, American United Brethren clergyman: b. Dillenburg, Germany, 4 June 1726; d. Baltimore, Md., 17 Nov. 1813. He was ordained in the Reformed (German) Church ministry at Herborn in 1749 and in 1752 was sent as a missionary to America, where he first settled at Lancaster, Pa., thereafter having charge of the congregations at Tulpehocken and York, Pa., and of Frederick, Md. At Lancaster he experienced what he termed a change of heart and as a result introduced the innovations of class-meetings, open-air meetings and prayer-meetings, and frequently made lengthy itinerant tours, founding what later became a new sect, the United Brethren in Christ. In 1774 he assumed charge of the parish at Baltimore where he remained for nearly 40 years. He was a man of great learning and wide influence; he co-operated with the Methodist preachers who came to Pennsylvania and Maryland; the movement which he headed gradually developed a separate organization; in 1800 he was elected bishop; and at his death the church had in its service about 100 preachers and 20,000 members. Consult 'Life,' by Drury (1884).

OTTERBEIN UNIVERSITY, founded in 1847 at Westerville, Ohio, under the auspices of the United Brethren in Christ. It was chartered with full university privileges, and was the first educational institution established under the control of the United Brethren; it was named in honor of Philip William Otterbein (q.v.). Its organization includes a college department, a preparatory department, with a three-years' course, and post-graduate, normal, music and art departments. The college work is arranged in two courses, classical and philo-

sophical, leading to the degrees of A.B. and Ph.B. The university has been coeducational from the first; and there is a dormitory for the women students on the campus. The Christian Association building was the first of its kind in the State. In 1923 the library contained 19,000 volumes; the buildings and grounds were valued at over \$1,000,000, including the productive funds, and the annual income was \$160,000. The students numbered 520 and it had a faculty numbering 36.

OTTLEY, ȯt'li, Robert Lawrence, English Anglican clergyman: b. Richmond, Yorkshire, 2 Sept. 1856. He was educated at Oxford, took orders in the Established Church, was principal of Pusey House, Oxford, in 1893, has been rector of Winterbourne Bassett, Wiltshire, from 1897 and canon of Christ Church, Oxford, and Regius professor of pastoral theology at Oxford since 1908. He has published 'Lancelot Andrewes' (1893); 'The Doctrine of the Incarnation' (1895); 'Aspects of the Old Testament' (1897); 'The Hebrew Prophets' (1898); 'Short History of the Hebrews' (1901); 'The Grace of Life' (1903); 'The Religion of Israel' (1905); 'Christian Ideas and Ideals' (1909); 'The Rule of Faith and Hope' (1911); 'The Rule of Life and Love' (1915); 'The Rule of Work and Worship' (1915).

OTTO, King of Bavaria: b. Munich 1848; d. Furstenried, near Munich, October 1916. Otto Wilhelm Luitpold Adalbert Woldemar became king in 1886, when his elder brother, King Ludwig II, was declared insane. The latter drowned himself and his doctor—who tried to save him—in Starnberg Lake. But Otto had already been declared insane as well, some 10 years earlier, and had been confined near Munich under restraint. His uncle, Prince Luitpold, acted as regent from 1886 to 1912, when he died. It was then decided to depose the insane "king in name only" and make his cousin, Ludwig III, the present ruler, king in his stead. The family taint overcame Otto in the early seventies. Though he displayed no sign of intelligence or any human qualities, his enormous natural physical strength held out for over 40 years of his incarceration.

OTTO, John Conrad, American physician: b. near Woodbridge, N. J., 1774; d. 1844. In 1792 he was graduated at Princeton with the degree of A.B., after which he attended the medical department of the University of Pennsylvania, where he was graduated with the degree of M.D. in 1796. He established his practice in Philadelphia and from 1813 to 1838 was physician and clinical lecturer at the Pennsylvania Hospital. Dr. Otto was the first physician to report hæmorrhagic disposition as an hereditary trait in certain families. Consult his 'Account of an Hæmorrhagic Disposition in Certain Families' (1803).

OTTO. See OTHO.

OTTO ENGINE. See INTERNAL COMBUSTION ENGINE.

OTTO AND LANGEN ENGINE. See INTERNAL COMBUSTION ENGINE.

OTTO OF ROSE. See ATTAR.

OTTOIA, ȯt'ȯya, a genus of fossil annelids found in the Burgess shale of certain formations in British Columbia. It has an

elongated cylindrical body, made up of several segments. The mouth is surrounded by a ring of hooks.

OTTOMAN (ôt'ô-man) **EMPIRE**, or **EMPIRE OF THE OSMANLIS** (*Osnali Vilayeti*), formerly comprehending all the tributaries really or nominally under the dominion of the Sultan of Turkey. See **TURKEY**.

OTTUMWA, ô-tûm'wâ, Iowa, city, county-seat of Wapello County, on the Des Moines River, and on the Chicago, Burlington and Quincy; the Chicago, Rock Island and Pacific; the Iowa Central; the Chicago, Milwaukee and Saint Paul and the Wabash railroads, about 80 miles southeast of Des Moines. It was settled in 1849 and in 1851 was incorporated. It is in a productive agricultural region and in the centre of Iowa's great bituminous coal-fields. It has good water power which combined with abundance of coal tends to develop manufacturing industries. The chief industrial establishments are mining and agricultural implement works, foundries, iron works, pork-packing plant, flour mills, starch factory, coal and lumber yards, manufactories of boilers, engines, tools, wagons, brick and tiles, cigars, grain elevators, stoves and candy. It is the trade and manufacturing centre of southern Iowa. The prominent buildings are the United States government buildings, the Young Men's Christian Association building, opera-house, the Union Railroad Station, courthouse, churches, schools and library. The educational institutions are Saint Joseph's Academy, a high school, public and parish schools and a public library. It is under the commission form of government. The waterworks are municipal property. Pop. 23,003.

OTUMBA, ô-toom'bâ, Mexico, town, state of Mexico, on the Mexican railroad, 30 miles northeast of the City of Mexico. It is the ancient Indian pueblo of Otompan, inhabited probably by the Otomi Indians. Here Cortes defeated the Aztecs in a desperate battle 7 July 1520 during his retreat from the City of Mexico. Pop. 2,500.

OTWAY, ôt'wâ, Thomas, English dramatist: b. Trotton, Sussex, 3 March 1652; d. Tower Hill, London, 14 April 1685. He was educated at Winchester College, and at Christ Church, Oxford. An appearance on the stage in Mrs. Aphra Behn's company in London in 1671 was unsuccessful and he returned to Oxford for a time, only to leave without a degree in 1674, and after a year in the army to return to London as an author. 'Alcibiades' (1675) and 'Don Carlos' (1676), especially the latter, which may be paralleled with Schiller's play, being taken from the same French original by St. Real, were unusually well received and won for Otway the favor of Betterton. Adaptations of Molière and Racine followed, one of which, 'The Cheats of Scapin,' held the stage for 100 years. In 1678 Otway essayed the comic with the prose play 'Friendship in Fashion,' another great success in his own day, though marked by much indecency. But Otway did not profit by his success, what with drink and various amours, notably his passion for Mrs. Barry, who played in most of his plays and was mistress of the Duke of Rochester. He left London for the army (1678-79), and upon his return wrote 'The Orphan'

(1680), a comedy called 'The Soldier's Fortune' (1681), 'Venice Preserved' (1682) and another comedy, 'The Atheist' (1684). The two comedies are little better than worthless; whereas the two tragedies, 'Venice Preserved' ranking the higher, are by far the most powerful of the contemporary stage, being remarkable particularly for the simple and strong delineation of the passions, and being generally held the most pathetic and provocative of tears of the whole English drama. Otway wrote much miscellaneous verse, satires, dedications, prologues and epilogues, but all contemporary and early biographers agree that he died in want, though they differ as to details. 'Venice Preserved' enjoyed a European repute, there being versions in French, Dutch, German, Russian and Italian; with 'The Orphan' and 'The Soldier's Fortune' it is contained in the 'Mermaid Series' (1891). (See **VENICE PRESERVED**). A complete edition of Otway is that by Thornton (1813). Consult De Grisy, 'Etude sur Thomas Otway' (1868); Mosen, 'Ueber Thomas Otways Leben und Werke' (1875); Löwenberg, 'Ueber Otways und Schillers Don Carlos' (1886).

OUACHITA (wâsh'i-tâ) **COLLEGE**, established at Arkadelphia, Ark., in 1886, under the control of the Baptist denomination. The work of the college is in two courses, classical and literary, and the degrees of bachelor of arts and bachelor of letters are conferred. There is also a preparatory department. The college is coeducational, and the number of women in attendance averages about one-half the total number of students. The income is derived from tuition fees, there being no endowment; in 1923 the income amounted to \$75,000; the grounds and buildings were valued at about \$350,000. The library contained 7,000 volumes; the students numbered 301 and the faculty 21.

OUAKARI, wâ-kâ're, a South American monkey of the genus *Brachyurus*, remarkable for the extreme shortness of the tail, and for the great length of the whitish hair upon the body, while the head is almost bald and the bare skin of the face is brilliant red. These small monkeys abound in the Brazilian forests, where three species are known, and one of which (*B. uakaria*) is among those most often seen and best liked as pets. Consult Bates, H. W., 'The Naturalist on the River Amazon.'

OUANANICHE, wâ-nâ-nêsh', a landlocked relative of the Atlantic salmon, named *Salmo ouananiche*, and often written winninish, wananiche and in various other ways. It inhabits various lakes and ponds in eastern Quebec and Labrador, but is most familiar in and about Lake Saint John, north of Quebec. From most of its stations it can go to and return from the sea if it pleases, but never seems to do so. This salmon differs very little from a typical salmon except in its smaller size, and most ichthyologists have held it, and the similar Sebago salmon, to be only local varieties of *Salmo salar*; but Jordan now regards both as separate species. The largeness of the eye and of the black spots are conspicuous distinguishing characteristics among others. "As a game fish," says Jordan, "those who have had experience with the ouananiche think it has no equal. They may be taken at any time between the going out of the ice and the middle of September, though the best fishing is said

to be late in May. During the early part of the season it may be taken with bait of worms, pork, pieces of chub or even ouananiche itself along the shore of Lake Saint John. It is occasionally taken then with the artificial fly, but fly-fishing for the ouananiche is usually not a successful method of capturing it." The literature of American angling abounds with descriptions of this fish and its sport, and special treatises upon it have been written by McCarthy, Chambers, Van Dyke and others.

OUBLIETTE, oo-bli-ét', a secret dungeon or pit constructed in old castles, forts and other buildings, in which were confined persons condemned to perpetual imprisonment or to secret death. It was usually entered by a staircase or steps reaching to the top of the chamber, in the floor of which was an opening into the dungeon. This opening served also for the admission of light and air.

OUDENARDE, oo'dē-nārd', or **OUDE-NAARDE**, Belgium, town in the province of East Flanders, on the Scheldt, to the southwest of Ghent 15 miles, and at the junction of the Brussels-Kortrijk, the Oudenarde-Mouscron and the Bilton-Ghent railways. It contains a number of remarkable buildings, among them the recently restored late Gothic, 16th century Rathaus with its portals by Paul van der Schelden, a masterpiece in wood carving; the Walpurgis Church (partly Romanesque of the 12th century and partly 14th and 15th century Gothic); the Liebfrauenkirche, an 18th century transition edifice; the School of Music, Bishop's College, etc. Its chief industrial resources are derived from the linen and cotton factories, bleacheries, dyeing establishments and tanneries. The old tapestry industry exists no more. This was the location in 1708 of the decisive victory of the allies under Marlborough and Prince Eugène of Savoy over the French under Vendôme and the Duke of Burgundy. It belonged to France from 1745-48. In 1910 it had a population of 6,956. Consult de Pauw ('La conspiration d'Oudenarde, 1342') (Ghent 1879). The town fell within the area of the German occupation early in the European War.

ODUH, owd, or **OUDE**, British India; (1) a town (also called Ajodhya) on the right bank of the Gogra, 77 miles east of Lucknow and forming part of the municipality of Fyzabad. It is greatly venerated by Hindus; but its ancient temples are in ruins, and its only structures deserving notice are a mosque built by Babar, and some Mohammedan tombs. Pop. 23,000. (2) A province politically attached to and forming with Agra the United Provinces of Agra and Oudh (q.v.) prior to 1901 known as the Northwest Provinces. Oudh is bounded on the north by Nepal and on the other sides by Agra, the lieutenant-governor of which administered Oudh as chief-commissioner from 1877 to 1902. Oudh is distinguished by an independent judicial system. The area is 23,966 square miles; the surface mostly level, very fertile and watered by the Gogra, Gunti and other tributaries of the Ganges. The Ganges itself forms nearly all its southwest boundary. There is a large forest area in the north. Oudh was formerly a Mogul province, and became subordinate to the British after the battle of Kalpi in 1765. In 1801 Gorakhpur and some other eastern districts were annexed from this

territory to the British dominions. In 1819 the vizier threw off his nominal dependence on the Mogul sovereign and assumed the title of king. A disputed succession, and partial revolt in 1837, were the chief subsequent events until 1856, when complaints of misgovernment led to the annexation of the country to the British dominions, an annual pension of £120,000 being settled on the king. This measure, however, produced much dissatisfaction, and when, in 1857, the Mutiny broke out, most of the Oudh sepoys joined it, and the siege of Lucknow resulted. (See INDIAN MUTINY). Agriculture has made great advances, the area under crop having largely increased. Wheat, barley, rice, sugar, indigo and other products are raised in large quantities; in some districts a vast amount of nitre effloresces on the soil. Over 73 per cent of the population is engaged in agriculture; the province contains what is probably the densest rural population of any equal area in the world. Oudh is rich in historical sites. The province includes the two divisions of Lucknow and Fyzabad. Lucknow is the capital; other towns are Myzabad, Shahabad and Bharaich. Pop. 12,558,004 (predominantly Hindu; Mussuhmans 1,700,000). See UNITED PROVINCES OF AGRA AND OUDH.

UDINOT, oo'dē-nō, Charles Nicolas, DUKE OF REGGIO, French marshal: b. Bar-le-Duc, France, 26 April 1767; d. Paris, France, 13 Sept. 1847. Entering the army he had attained the rank of captain at the outbreak of the Revolution. He joined forces with the populace but crushed an uprising in his native district in 1790, and in 1794 was given command of a brigade. In the war with Prussia and Austria he won distinction, in 1799 became general of division, and was thereafter much trusted by Napoleon, receiving the command of 10 battalions in 1805. He was at Austerlitz and Jena, and at Ostrolenka, Russia, in 1807 he routed the Russians; at Friedland in 1807 and at Wagram in 1809 his bravery was so marked that after the latter battle he was made marshal of France and Duke of Reggio. In 1810 he occupied Holland, and in the unfortunate campaign against the Russians in 1812 he earned high praise for his skilful generalship. In the battles between the French and the allies he played a prominent part, was defeated at Gross Beeren and engaged at Leipzig; and he was loyal to Napoleon to the last, but after the restoration of the Bourbons took office under them. In 1823 he led the invading army into Spain, acted as governor of Madrid for a time, and became governor of the Invalides in 1842.

UDINOT, Charles Nicolas-Victor, DUKE OF REGGIO, French general, son of the preceding: b. Bar-le-Duc, France, 3 Nov. 1791; d. Paris, France, 7 July 1863. He was a prominent figure in the war in Algeria, was later appointed commander-in-chief, and in 1848 led the attack upon Rome. For his protests against the *coup d'état* in 1851 he was arrested, but his release followed shortly, whereupon he retired from public life.

OUGREE, oo'grā', Belgium, town in the province Liège, on the Maas and the Liège-Namur Railway. It has extensive blast furnaces, rolling mills, machine works and coal mines. In 1910 it had 17,088 inhabitants.

OUIDA, wē'da, penname of Maria Louise [de la] Ramée, English novelist: b. Bury, Saint Edmunds, 7 Jan. 1839; d. Florence, Italy, 25 Jan. 1908. Her father, Louis Ramée, was said to be of Norman (Jersey) extraction; her mother, Susan Sutton, was English. In her teens she went to live in London and began to write for *Colburn's New Monthly Magazine* and for *Bentley's Magazine*. Originally published in serial form as 'Granville de Vigne: A Tale of the Day,' her first novel appeared in book form as 'Held in Bondage' (1863). Using as a pseudonym her Christian name as pronounced by a baby sister, there speedily followed 'Strathmore' (1865); 'Chendos' (1866); and 'Under Two Flags' (1867), which established her reputation as a story-writer. Exceedingly dramatic, abounding in high-pitched sentiment and attractive description, unconventional, of doubtful morality and taste, they possessed, however, undoubted literary merit with a strong popular appeal. Among notable later books were 'Tricotrin' (1869); 'Puck' (1870); 'A Dog of Flanders, and Other Stories' (1872); 'Two Little Wooden Shoes' (1874). In 1874 Ouida went to live in Florence where she wrote 'Moths' (1880); 'In Maremma' (1882); 'Bimbi: Stories for Children' (1882); 'Ruffino' (1890); 'The New Priesthood' (1893); 'The Mascarenes' (1897); 'The Waters of Edera' (1900); 'Street Dust' (1901). She acquired considerable wealth by her writings but due to her extravagant mode of living and her pride in refusing assistance of friends she was always in financial difficulties. The Italian government made her a generous grant of money; the British government granted her a civil list pension which was augmented by another from the English Literary Fund, but her last years and death were marked by tragic poverty.

OUIMET, wē'mē', Joseph Alderic, Canadian statesman: b. Sainte Rose, Quebec, 20 May 1848. He was educated at the Séminaire de Sainte Thérèse and at Victoria University, Cobourg. In 1870 he was called to the bar and practised thereafter at Montreal where he was soon recognized as one of the foremost legal lights in the province. From 1873 to 1896 Ouimet sat in the Dominion House of Commons as Conservative member for Laval. In 1887-91 he was speaker of the House and served as Minister of Public Works from 1892 to 1896. For the 10 years from 1896 to 1906 Ouimet served as puisne judge of the Court of King's Bench of Quebec province.

OUISTITE, wī'stī-tī. See MARMOSSET.

OULESS, oo-lēs, Walter William, English painter: b. Saint Heliers, Jersey, 21 Sept. 1848. He was educated at Victoria College in his native town, and at 16 became a student at the Royal Academy, where he was a constant exhibitor after 1869. He was elected an associate in 1877 and a full member in 1881. About 1872 he applied himself to portrait-painting, in which he attained a high rank. Among his sitters were Darwin, Bright, Cardinals Newman and Manning, Lord Roberts, Frederic Harrison and the Duke of Cambridge. He was awarded a gold medal at the Paris International Exhibition of 1878, and also at the Berlin Exhibition of 1886.

OUNCE, (1) the snow-leopard (q.v.); (2) in South America the jaguar (q.v.).

OUNCE, a twelfth part of any magnitude, whether of length, surface or capacity. In Troy weight the ounce is the 12th part of the pound; in avoirdupois the ounce is the 16th part of a pound. See WEIGHTS AND MEASURES.

OUR AMERICAN COUSIN, an English comedy by Tom Taylor, produced in 1858. There is a Yankee character in the play, originally created by Joseph Jefferson (q.v.). Lincoln was in attendance at a performance of this comedy at Ford's Theatre, Washington, when he was assassinated.

OUR LADY OF ANGELS, Seminary of, Niagara Falls, N. Y., the ecclesiastical department of Niagara University (q.v.), founded 21 Nov. 1856. The object of the seminary is the training of candidates for the Catholic ministry. The scholastic year extends from September to June and consists of two terms. The first term ends on the 1st of February; the second ends with the close of the scholastic year. The course of studies embraces two years of philosophy and four years of theology. Recitations are in Latin. Two oral and two written examinations are held every year. Scholastic disputations in dogmatic theology and philosophy and the solving of "cases of conscience" in moral theology are a part of the regular class work. The seminary is under the care of "The Priests of the Congregation of the Missions" (Vincentians or Lazarists). "Old Niagara" as the seminary is affectionately called, celebrated its 60th anniversary in 1916, with a commemoration of the hundreds of priests "men rich in virtue and endowed with wisdom," who from its classes entered the ministry and throughout the nation in the churches, schools and charitable institutions which they were instrumental in creating, reared noble monuments to their zeal, devotion and self-sacrifice.

OUR LADY OF GOOD COUNSEL, Sisters of. See ORDERS, RELIGIOUS.

OUR LADY OF LOURDES. See ORDERS, RELIGIOUS.

OUR LADY OF LOURDES, Brothers of. See ORDERS, RELIGIOUS.

OUR LADY OF MERCY, Military Order of. See ORDERS, RELIGIOUS.

OUR LADY OF PERPETUAL HELP, Sisters of. See ORDERS, RELIGIOUS.

OUR LADY OF SION. See ORDERS, RELIGIOUS.

OUR MUTUAL FRIEND, a novel by Charles Dickens, published in England in 1864-65. The scene is laid in London and its immediate neighborhood. Among the characters which this story has made famous are Miss Jenny Wren, the doll's dressmaker; Bella Wilfer, "the boofer lady"; the Golden Dustman, Mr. Boffin; and Silas Wegg, employed by Mr. Boffin, who is at first delighted with the services of "a literary man with a wooden leg."

OURAY, oo-rā', Indian chief: b. Colorado, 1820; d. Los Pinos Indian agency (Colo.) 24 Aug. 1880. He was the leader of the Uncom-

pahgre Utes, and while protecting the interests of his tribe was friendly to the whites, with whom he always kept faith. He spoke both English and Spanish. Several times he visited Washington to appeal on behalf of his people.

OURAY, Colo., town, county-seat of Ouray County, on the Uncompahgre River and on the Denver and Rio Grande Railroad, 160 miles west-southwest of Colorado Springs. It is at an elevation of over 7,000 feet, at the base of Mount Hayden, and in a region of grand mountain scenery. Its hot springs make it a favorite health resort. It is also the local trade centre and shipping point of the surrounding mining region, which is rich in gold and silver. It contains a miners' hospital. Pop. 1,165.

OURIQUE, ô-rê-kê, Portugal, town in the province Alemtijo, and celebrated on account of the victorious battle of this name gained (1139) by Alfonso I over the Moors near here. The battle assured him the kingdom of Portugal.

OURO-PRETO, ô'roo prä'too, Brazil, city, state of Minas Geraes, 175 miles north of Rio de Janeiro; elevation, 3,800 feet. Rich gold deposits were found in the vicinity and the chief industry was formerly gold-mining, but the mines have mostly been abandoned and the prosperity of the city has in consequence declined. It was originally the capital of Minas Geraes, but the state government was moved to Minas in 1894. It is built on several hills and surrounded by mountains; the streets are narrow and irregular, but some of the modern houses are well built. It is connected with Rio de Janeiro by rail, and with the towns to the north and east by highway, and carries on an active trade. Pop. 15,000.

OUSE, ooz, England, (1) a river of Yorkshire also called the **NORTHERN** or **YORKSHIRE** Ouse, formed by the junction of the Swale and Ure, and after a southeast course of 45 miles, uniting with the Trent to form the estuary of the Humber. Its principal affluents are the Wharfe and the Aire from the west, the Don from the south and the Derwent from the north. (2) The **GREAT OUSE** rises near Brackley in the county of Northampton, flows in a general northeasterly direction, traverses the counties of Buckingham, Bedford, Huntingdon, Cambridge and Norfolk, and falls into the Wash at King's Lynn, after a course of 156 miles, for the latter two-thirds of which it is navigable. Among its affluents is (3) the **LITTLE OUSE** or **BRANDON RIVER** which, after a course of 30 miles, joins it at the confluence of the river Stoke, and the New Bedford and Wisbech Canal.

OUSELEY, ooz'li, **SIR Frederick Arthur Gore**, English composer and musician: b. London, 12 Aug. 1825; d. Hereford, 6 April 1889. He was a son of Sir Gore Ouseley (q.v.). He was graduated B.A. in 1846 from Christ Church, Oxford; succeeded to the baronetcy by his father's death in 1844, took orders, and held several metropolitan curacies from 1849 to 1851. Having graduated as doctor of music at Oxford in 1854, he was appointed precentor of Hereford Cathedral in the following year, and also became professor of music in the university. In 1866 he was made a canon residentiary of Hereford Cathedral. From earliest childhood

Ouseley showed remarkable musical ability and extraordinary accuracy of ear. He composed an opera of great promise when only eight. His published compositions include two oratorios, 'The Martyrdom of Saint Polycarp' (1855), and 'Hagar' (1873); nearly 100 anthems, and many other compositions of a religious nature; besides overtures, glees, solos and quartets. He wrote three valuable works on musical theory: 'A Treatise on Harmony' (1868); 'A Treatise on Counterpoint, Canon and Fugue' (1869); and 'A Treatise on Musical Form and General Composition' (1875). He was the founder of the church and college of Saint Michael, Tenbury (1856), and to it bequeathed his splendid musical library.

OUSELEY, Gideon, Irish Methodist missionary: b. Dunmore, Galway, 24 Feb. 1762; d. Dublin, Ireland, 13 May 1839. His father, who belonged to a family settled in Ireland since 1625, was a deist, who, however, brought up his son with a view to his entering the Roman Catholic priesthood. A frivolous youth was followed by marriage at 20 and by the dissipation of both his own and his wife's fortunes. A severe gunshot wound deprived him of the sight of one eye; at the same time he came under the influence of pious Methodist soldiers, was converted in 1789, began work as a preacher; in 1792 he and his wife opened a girls' school at Sligo, and in 1799 he was received into the Methodist conference. For 50 years he preached the gospel, largely in the nine Ulster counties, addressing thousands of gatherings, chiefly in the open air at fairs, wakes, etc., and generally speaking from horseback. During the rebellion of 1798 he was in peril for his life; but the heart-reaching power of his discourses, his fire and enthusiasm, joined to the Irish grace of humor, made his zealous labors acceptable not only to Wesleyans but to other Protestant denominations. He would preach as many as 20 sermons a week. He was the author of some controversial works, including 'A Short Defence of the Old Religion' (1812); 'Rare Discoveries' (1829). Consult the 'Memoir' by Reilly (1847); and the 'Life' by Arthur (1876).

OUSELEY, **SIR Gore**, English diplomat and Orientalist: b. Limerick, Ireland, 24 June 1770; d. Beaconsfield, Buckinghamshire, England, 18 Nov. 1844. In 1787 he went to India, where he engaged in business, and also gave considerable attention to the study of Oriental languages and customs, particularly the Persian, Bengalese and Hindu. After his return to England he was created a baronet (1808), and in 1810 was appointed English Ambassador Extraordinary to Persia, and through his intimate knowledge of the Persian language and his skilful diplomacy was successful in arranging a treaty between England and Persia, which was concluded in 1812 but never finally ratified. He was also instructed in 1813 to mediate between Russia and Persia, and through his efforts a treaty was signed suspending war between the two nations. In 1815 he returned to England, and in 1820 was admitted to the privy council. He was an able Oriental scholar, was one of the founders of the Royal Asiatic Society of London, and in 1842 became president of the Society for the Publication of Oriental Texts. 'The Gulistan of Musle-Huddeen Shaik Sâdy

of Sheerez' was printed under his direction (1809); his own work, 'Biographical and Explanatory Notes on the Persian Poets' was published after his death (1846).

OUSELEY, Sir William, English Orientalist: b. Monmouthshire, England, 1767; d. Boulogne, France, September 1842. He was educated privately and later in Paris, but in 1788 he entered the army. Tiring of military life and desirous of continuing his study of Oriental languages, he left the army in 1794 and entered the University of Leyden. Thereafter he devoted himself to further study and to literature, and was knighted in 1800, but in 1810 accompanied his brother, Sir Gore Ouseley, Ambassador to Persia, as his private secretary. He published 'Persian Miscellanies' (1795); 'Oriental Collections' (1797-99); 'Travels in Various Countries of the East' (1819-23), and translated the geography of Ibn Haukal (1800).

OUSELEY, Sir William Gore, English diplomat: b. London, 26 July 1797; d. there, 6 March 1866. He was the son of Sir William Ouseley (q.v.). He was early engaged in the diplomatic service; and in 1825 was connected with the British legation at Washington, and at that time married a daughter of Van Ness, governor of Vermont. He later was appointed to several responsible diplomatic positions in South America; and was sent on special missions to the United States and to Central America. He published 'Remarks on the Statistics and Political Institutions of the United States' (1832); 'Notes on the Slave Trade' (1850); and 'Views in South America, from Original Drawings' (1852). He was created K.C.B. in 1852.

OUSSANI, Gabriel, American Orientalist: b. Bagdad, Asiatic Turkey, 1 Aug. 1875. He was educated at the Patriarchal Seminary, Mosul, Turkey, at the Propaganda, Rome, also at Paris and at Johns Hopkins University, Baltimore, under Paul Haupt. He was ordained priest of the Chaldean rite and came to New York in 1900, was Fellow in Semitic languages at Johns Hopkins in 1901-04, and professor of Hebrew, ancient history and Italian at Cathedral College, New York, and lecturer on Biblical and Oriental history and archaeology at Saint Joseph's Seminary, Dunwoodie, N. Y., in 1904-07. In 1907 Dr. Oussani was appointed professor of early church history, Old Testament history and patrology and librarian at Saint Joseph's Seminary. He visited the ruins of Assyria and Babylonia and traveled in the Levant for purposes of research. He is member of the American Oriental Society and the Society of Biblical Literature and Exegesis. He is a frequent contributor to periodicals and reviews and contributed also to 'The Catholic Encyclopedia.'

OUSTER, *in law*, the act of dispossessing one, as of a freehold or chattels real. An ouster differs from a trespass in that the latter is temporary and usually without claim to the property. Ouster of a freehold may be effected in three ways; by abatement, or wrongful entry before the heir or devisee, at the death of the person seized; by intrusion, or entry before the reversioner or the remainderman, at the death of the tenant for life; by disseisin, or expulsion of the person lawfully in possession.

Ouster of chattels real is effected by disseisin only. In disseisin the expulsion must be forcible or fraudulent.

OUT OF THE CRADLE ENDLESSLY ROCKING. In the New York *Saturday Press* of 24 Dec. 1859 appeared a lyric poem by Walt Whitman entitled 'A Child's Reminiscences.' In the following year this title was changed to 'A Word out of the Sea.' The poem has finally come to be known by its initial line, 'Out of the Cradle Endlessly Rocking,' and has established itself not only as one of the finest of Whitman's lyrics but as one of the most suggestive and impressive poems in American literature. It is a reminiscence of a night in May in the poet's boyhood, on the coast of northern Long Island, under the moonlight, where a mocking-bird is calling for its dead mate, the sea is singing its song of death and the boy "is listening, absorbing, translating." Few poems have so entirely and exquisitely fused nature and human emotion; the "setting" formed of moonlight, the sea and the bird, is no mere background: in its reaction upon the boy it is the very soul of the poem (compare 'When Lilacs Last in the Dooryard Bloomed,' q.v.). In his chant of the mocking-bird Whitman has succeeded more nearly than any other poet in rendering articulate the bird's song of joy and pain. From this song and the song of the sea, says the poet, "a thousand singers, a thousand songs, have started to life within me." Perhaps no other poem has with such pure emotion suggested the subtle and indescribable awakening of a poet's genius. Whitman's power of phrasing and wide variety of rhythm and harmony so entered into the making of this poem that the sympathetic reader leaves it with the sense of having witnessed a miracle, of having actually shared a profound emotional experience.

MARION TUCKER.

OUTAGAMI, a name applied to the Fox Indians (q.v.).

OUTCROP, an exposure of rock. Specifically the term is limited to an actual exposure of the bedrock, without soil cover. The term, however, is used in a more expanded sense to indicate an area where a given bed of rock is the formation next under the surface soil, even though not actually exposed. For example, the Cambro-Ordovician outcrops over most of the central Ozarks, mean not that the Cambro-Ordovician actually is exposed over all that area, but that it is the rock next beneath the soil cover.

OUTDOOR THEATRES have recently found a wide revival in every part of the world, particularly in our own Western States. The uncertainty of the weather has always been a factor tending to retard the growth of the theatre out-of-doors, making the performances periodical or fitful, even in countries where fair weather is invariable. The classic performances in the amphitheatres of Athens, it will be remembered, were part of the religious seasonal celebrations and were not perennial. In this regard it should be remarked that the Shakespearean theatre was not an outdoor theatre, as it has been so often described, but a roofless theatre; and, therefore, something quite distinctive. On the other hand, the pres-

ent-day garden theatres of Italy, like the theatres of ancient Greece, are wide open to all the winds. The most renowned of these are the stately garden theatre of Villa Sergardi, near Sienna in Tuscany; the little garden theatre, Villa Marlia, near Lucca, one of the best of its kind in all Italy; and, the largest garden theatre in that country, at Castelnuovo, near Palermo. This last has a wall of stucco built at the back of the stage lawn with painted scenery: a highly artificial and incongruous effect in a garden theatre. The Royal Garden Theatre in Dresden, Saxony, is one of the largest and best equipped on the Continent. In the United States a number of such theatres are owned by private persons; notably the 'Outdoor Players' extraordinarily beautiful Nature Theatre, belonging to Miss Marie Ware Laughton, at Peterboro, N. H.; one in the grounds of R. R. Conklin, Huntington, Long Island; a remarkably handsome, solid structure on the estate of George C. Booth, Cranbrook, Mich.; another at Brookside, Mount Kisco, N. Y.; and many more attached to universities and other educational institutions (see COLLEGE DRAMATICS). A world-famous theatre is that built at Point Loma, near San Diego, Cal., by a theosophical order, the Universal Brotherhood Organization.

These, like practically all the large completed outdoor theatres of the United States, have been fashioned after the Greek model. Exceptions are found in those theatres that are rustic from necessity or by design. Of the latter type a fine specimen is the Redwood Forest Theatre of the San Francisco Bohemian Club, made famous by its annual original 'Bohemian Jinks,' in which men of national and international celebrity have been concerned. These festivals (for men only) have been partly described in the club volume edited by Mr. P. Garnett (San Francisco 1912) and a more recent list of the performances has been published in a special bulletin of the American Pageant Association. For excellent decorative and mechanical lighting effects for evening performances out of doors, consult the article in the *Architectural Review* (Boston, September 1916) by Mr. Claude Bragdon, an architect of accomplishment in this department, who spent many months in experimentation to achieve his remarkable effects. While many of the classics have been largely adapted to the outdoor theatres of all kinds, there exists, at the same time, a stronger and quite successful tendency toward bending writers to originate plays for the strict conditions of the open air. For the English outdoor play of the 17th and 18th centuries, consult Greg, W. W., 'Pastoral Poetry and Pastoral Drama' (London 1906), the most important work on the subject, containing a valuable bibliography. The French work on pastoral plays is Marsan, Jules, 'La Pastorale Dramatique' (Paris 1905). The German standard authority is Klein, J. L., 'Geschichte des Dramas' (Vol. V, Leipzig 1867).

Bibliography.—Budd, Katherine C., 'Every Lawn a Theatre' (in *World's Work*, Vol. XXII, New York 1912); Cheney, S., 'Garden Theatres' (in *Country Life*, New York, March 1915); Craig, Gordon, 'Open Air Theatres' (in the *Mask*, Florence, Italy, October 1909); Dickinson, T. H., 'The Case of American Drama' (New York 1915), contains a chap-

ter on 'The Theatre in the Open'; Hackett, F., 'Open Air Performances' (*New Republic*, New York, 12 June 1915); Savits, Jozza, 'Das Natur-theater' (Munich 1910); Stevens, A. S., 'The Open-air Theatres of France' (in the *Metropolitan Magazine*, Vol. XXIV, p. 133, New York 1906); Stoll, H. F., 'Notable Open-Air Theatres in America' (in the *Theatre*, New York, July 1911); Waugh, Frank A., 'Garden Theatres' (Boston 1917), the standard work in English on the subject.

In the broader lines of outdoor theatricals consult articles listed under the special headings: COLLEGE DRAMATICS; COMMUNITY DRAMA; FESTIVAL; MASQUES; PAGEANT.

OUTLANDERS. See **UITLANDERS.**

OUTLAWRY, an ancient custom in Great Britain of putting a person out of the protection of the law; thus an outlaw could be killed at sight like a wild beast; but once captured, his life was in the king's hands. Outlawry in civil proceedings was formally abolished in 1879. In an act passed in 1870, however, abolishing forfeitures for treason and felony, it was expressly stated that nothing in the act was to affect the law of forfeiture consequent upon outlawry. But there is little need now for outlawing absconders from justice, since in most cases they can be laid hold of under treaties of extradition with foreign countries. The effect of outlawry is the forfeiture of the goods of the outlaw to the Crown, and he cannot receive and hold property given or devised to him. In the United States, outlawry was recognized in the Colonial days, but since the War of the Revolution the practice has been obsolete.

OUTLIER, an isolated mass of younger rock entirely surrounded by older sediments. Outliers are usually the result of normal erosion, as for example the hard layer of rock capping a mesa (q.v.), which has been separated from the continuous layer with which it was once connected. Contrasted with outlier is inlier, a mass of older rock entirely surrounded by younger beds, as where an anticline (q.v.) has been planed down by erosion, exposing the older beds at the centre. Outliers and inliers may be formed in other ways.

OUTRAM, oo'tram, Sir James, English soldier: b. Butterley Hall, Derbyshire, 29 Jan. 1803; d. Pau, France, 11 March 1863. He was educated at Marischal College, Aberdeen, and in 1819 went to India, where after commanding for some time a body of irregular troops he was appointed adjutant to the 23d Bombay Native Infantry. From 1835 to 1838 he was employed in subduing the rebel chiefs of the Mahhi-Kanta. In the last-mentioned year, as adjutant to Lord Keane, he took part in the Afghan War, and distinguished himself at the capture of Khelat, and by his dangerous ride in disguise through the enemy's country (1839). In various other capacities he displayed military talents of a high order, as well as admirable administrative qualities. In 1842 he was appointed commissioner to negotiate with the Ameer of Sindh, in which position he adopted views at variance with the aggressive policy of Gen. Sir Charles James Napier, and the consequence was an acrimonious correspondence between the two soldiers, carried on, however, by both in a spirit of good faith. Sir James

had the satisfaction in the end of knowing that his views were confirmed by the directors. His opponent gracefully styled him publicly the Bayard of India. In 1843 he defended the residency of Haiderabad against 8,000 Sikhs; was resident of Baroda 1847-51; Oudh in 1854. He successfully conducted the war against Persia. He landed at Bushehr 27 Jan. 1857, and by a series of brilliant victories brought the war to a satisfactory conclusion in three months. At the beginning of the Mutiny he had command of two Bengal divisions, and was chief commissioner of Oudh. During the first relief of Lucknow, however, he waived his rank and served as a volunteer under Havelock. He commanded at Lucknow until the second relief (by Sir Colin Campbell), directed the evacuation, and held the place until the third relief. He was made lieutenant-general and was created a baronet in 1858. He was the author of several works on his campaigns.

OUTREMONT, oo'tr-môn, Canada, town in Jacques Cartier County, province of Quebec, on the Canadian Pacific, the Canadian Northern and Grand Trunk railroads, five miles northwest of Montreal. It is in the main a residential suburb of its great metropolitan neighbor and has none other than small local manufactures. The Cedar Rapids and Shawinigan Falls furnish valuable water power. Pop. (1921) 12,997.

OUTWASH PLAIN. See VALLEY TRAIN.

OUTWORKS, in warfare. See FORTIFICATION.

OUVRARD, oo'vrâr, **Gabriel Julien**, French financier: b. near Clisson, Loire-Inferieure, 1770; d. England, 1846. Ouvrard became prominent as a financier during the Revolution, especially under the Directoire, when he became very wealthy. He lent huge sums to the state and also to Spain. Under the Napoleonic régime his financial operations grew apace and in 1802-04 he loaned the government about 300,000,000 francs. The great military campaigns of Bonaparte were financed by Ouvrard. A break with the emperor came and Ouvrard passed the years 1810-13 in prison. He was afterward sentenced to a term in prison for illegal methods on the Stock Exchange. After his release he went to live in England. He published a volume of 'Memoires' (1826).

OUZEL, oo'z'l, an old name, derived from the German, for several thrush-like birds of Great Britain and the United States. The name is sometimes applied in England to the black-bird (q.v.), and to the larger thrush (*Turdus torquatus*), distinguished by the broad lunate stripe of white across the breast and sides of the neck, which is provincially known as ring, rock, mountain or tor ouzel. The name is also given, in the form "water-ouzel," to a small wren-like bird (*Cinclus aquaticus*), congeners of which occur in various mountainous parts of the world, all very similar in appearance and habits. One species (*C. mexicanus*), is common in the Rocky Mountain region—a small, robust, short-tailed, short-winged, dark-colored bird which haunts the mountain-streams and is commonly known as "dipper," on account of its remarkable facility in diving. Its food consists almost exclusively of snails, young insects and other organisms which live in and about the

streams; and it has the power of seeking these under water, not only by diving, but by partly swimming and partly walking with fluttering wings along the bottom in search of its prey, remaining there "two or three minutes" if it pleases. It is a common bird in both the Rocky Mountains and in the Coast Ranges; and makes a large globular nest of mossy materials which it lodges in some crevice near a stream, often beneath the veil of a cataract. Consult Muir, in *Scribner's Monthly* (1878); Keyser, 'Birds of the Rockies' (1902); Coues, 'Birds of the Northwest' (1874); and British ornithologies.

OVAMBO, ô-vâm'bô, the Herero name for a people of the Bantu race residing in German Southwest Africa, calling themselves the Aajambo or "rich ones." They are divided into separate tribes, among which the best known is the Aandonga, and are said to number about 80,000. They are of very dark complexion, tall and robust and remarkably ugly, and are physically much like their neighbors, the Herero (q.v.). The hair is short, crisp and woolly. The men often shave it off, leaving the crown untouched; but the women stiffen it with a kind of red paste, in the manner practised in many other parts of Africa. The principal ornaments are heavy iron anklets, a profusion of cowries and other shells and beads of every size and color, so arranged as to hide a considerable part of the person. The men also wear a leather clout. Their staple food is grain and they are primarily agriculturists. The houses are of a circular form, with a circuit of 16 feet and a height not much exceeding four feet. These huts, arranged in groups, are enclosed by strong palisades. The domestic animals are oxen, sheep, goats, pigs, dogs and poultry. The arms consist of bows and arrows, a dagger, assegais and knob-keries. Though thus provided with weapons the Ovambo are peacefully disposed and industrious. There is a sharp division of labor between the various tribes. In the higher castes of nobles and priests, descent is traced by the mother. The chiefs have a despotic rule and there is a strong belief in sorcery.

OVANDO, ô-vân'dô, **Nicolás de**, Spanish soldier and administrator: b. Valladolid, Spain, about 1460; d. Madrid, Spain, about 1518. He was commander of the Order of Alcántara and politically one of the most powerful men of his day in Spain, where he was high in favor with Ferdinand and Isabel, joint sovereigns of the Spanish domains. In 1501 he was appointed successor to Boabdilla as governor of Hispaniola; in February 1502 he sailed from Spain with a fleet of 30 ships and 2,500 persons in his company and landed at San Domingo. Almost his first act as governor was to refuse aid to Columbus whom he would not allow to land at San Domingo and he permitted months to pass without sending aid when he knew Columbus was in sore straits at Jamaica. His treatment of the Indians was cruel in the extreme and one of the blackest deeds in his career was his treacherous massacre of the 84 caciques of Queen Anacaona at Xaragua and her subsequent execution. In the course of his despotic rule the number of Indians in his province was reduced to 60,000 in 1507 against 500,000 at the arrival of the Spaniards. Aside from his treatment of the Indians Ovando was an able gover-

nor and the colony flourished. He was recalled in 1509.

OVARIOTOMY. See **OVARY**.

OVARY, one of the paired glands which form the essential part of the organs of generation in the female, and produce the eggs or ova; it is homologous to the testis of the male, where spermatozoa originate. The ovaries are two elongated oval bodies, flattened from above downward, one on each side of the uterus, attached to the broad ligament. Each ovary is about one and one-half inches in length and one-third inch thick. It consists of many ovisacs or Graafian follicles or vesicles (in which the ova are developed), embedded in a stroma or framework, and also of blood vessels, nerves and lymphatics and is invested with a serous covering or membrane derived from the peritoneum. In females who have never menstruated, the surface of the ovary is smooth; after menstruation has been established it is rough and marked with scars, due to the rupture and closure of the Graafian vesicles. At undetermined periods, from puberty on, probably at or near the time of menstruation, the fluid (liquor folliculi) within certain ovisacs increases, distention of the sacs occurs and a rupture at the weakest point, with discharge of the ovum. This is ovulation, the function of the ovary. Most physiologists believe that ovulation is associated with menstruation, but some writers contend that menstruation may occur without accompanying ovulation, and vice-versa. Usually the ova, when discharged, are conveyed through the Fallopian tubes (q.v.) to the uterus. If the ovum unites with the spermatozoa of the male it becomes impregnated or fertilized. After the discharge of the ovum the Graafian vesicle usually fills with blood, which coagulates. The coagulum, squeezing out the serum, becomes decolorized, its periphery assumes a yellowish color and the resultant spot is the corpus luteum. The corpus luteum of pregnancy is larger and remains for a longer time than that formed when pregnancy does not occur. Ovarian grafting now occupies a recognized position in pelvic surgery, operations having been followed by most excellent results.

Diseases of the Ovaries.—The affections of the ovaries may be classified as malformations, displacements, functional disorders, inflammations and tumors. One or both ovaries may be congenitally absent. This condition is rare, and when it does occur it generally coexists with a want of development of the vulva, vagina and uterus. Sometimes the ovaries are undeveloped. In both these conditions the women lack constitutional vigor and development. Displacement of the ovary into the inguinal canal, or labia majora (hernia), is generally congenital, but may be caused by a strain or fall. Prolapse or dislocation of the ovary, causing it to sink downward toward the pelvic floor, results from a disturbance of the delicate adjustment of the organ, by an abnormal increase in its weight, a weakening of its supports or an unusual traction upon it. The functional affections are neuralgic in character. Ovarian neuralgia (ovarialgia or oöphoralgia), of which the principal symptom is sharp local pain, is frequently associated with hysteria or other neuroses, headache, intercostal neuralgia, etc., and it may be caused by a local engorge-

ment or induration pressing on sensitive nerves. Inflammation of the ovary (ovaritis or oöphoritis) may be acute or chronic. The acute form is often preceded by hyperæmia, or an excess of blood-supply at the time of the monthly period, from some obstruction of the venous circulation. Pain in the ovarian region, especially during menstruation, inability to walk and painful defecation are the principal symptoms of acute ovaritis. The inflammation is frequently associated with pelvic cellulitis and peritonitis and may be caused by injuries, gonorrhœal infection, puerperal sepsis and the acute exanthemata. Sometimes abscesses form, or sterility results. Chronic ovaritis is usually the result of an inflammation, acute or sub-acute, but may be caused by self-abuse, sexual excitement, etc. The connective tissue of the ovary thickens, decreasing the size of the organ (cirrhosis) and tends to the formation of cysts, that is to say, cystic degeneration. A sickening pain, tenderness and reflex neuralgias are symptoms. The tumors of the ovary are carcinoma, fibroma and papillomatous tumors. Pathological atrophy sometimes accompanies excessive obesity, while prolonged pressure by adhesions or tumor, interference with the vascular supply and removal of the uterus also cause this condition. Physiological atrophy follows the menopause. Hypertrophy may be caused by any inflammatory process which stops short of the formation of pus, as chronic constipation, prolapsus of the ovary, etc. Pure hypertrophy is very rare as is also tuberculosis of the ovary.

Ovariectomy.—This is the operation of modern surgery for removal of ovarian tumors or of ovaries themselves. It was first performed in the 18th century by Ephraim McDowell of Kentucky, and long considered exceedingly dangerous, but has been performed with great and increasing success, especially since the adoption of antiseptic treatment. See **ANATOMY, COMPARATIVE**; and consult 'Reference Handbook of the Medical Sciences' (Vol. VI, New York 1916).

OVEN, a closed, box-like chamber of any description in which a considerable degree of heat may be generated, used for baking, heating or drying any substance. The term is usually restricted to a close chamber for baking bread and other food substances; but ovens are also used for coking coal, in the art of metallurgy, in glass-making, pottery, etc. There is now a great diversity in the shape and materials of construction and modes of heating ovens. The old type of baker's oven, still very largely used, is a low arched chamber either of brick with a tile or stone sole, or built entirely of stone. The door is in front and the pans of dough are put in with a long wooden spade. In one class of these ovens the fireplace or furnace is placed in the front corner, with an opening admitting the products of combustion directly into the oven, while there is an exit flue on the other side. A remarkable apparatus for the economic preparation of food both as regards the expenditure of fuel and the saving of waste is the Aladdin Oven, invented by Edward Atkinson, of Boston. This apparatus has been developed from a study of the Scandinavian Cooking Box, much used in Norway and Sweden. This box consists of an outer case of

wood or other non-heat-conducting material, lined with hair felt. Into this cavity a metallic box, containing food with sufficient liquid heated to the boiling point, is placed and tightly closed in. The heat is thus retained for a long period, completing the process of cooking. On this basis was devised an outer oven of non-heat-conducting material in which, separated by a sufficient space for the circulation of heat, is placed a metallic oven or cooking chamber. Heat is passed from the top of a round-wicked kerosene lamp through a hole in the bottom of the outer oven. This heat passes around the entire inner oven, the products of combustion passing out at the same orifice at which the heat entered. There is no direct communication between the lamp or source of heat and the cooking chamber. By this apparatus a normal temperature can be maintained for a definite number of hours, either at the temperature of simmering or stewing at about 160° F., or at the temperature for baking and roasting not exceeding 300° to 320° F. By suitable arrangements thereto very little difference in temperature is found between the top and the bottom of the oven. The heat can be regulated by the size of the lamp and height of the flame. Meats, fish, vegetables and puddings can be cooked in the same chamber without the flavor of one being imparted to the other, the heat being kept below the distilling point of the animal fats or of the fruit and vegetable juices. In this apparatus two pounds of kerosene oil are computed to do the work of 120 pounds of anthracite coal burned in the ordinary stove or range and to do it in a more wholesome and appetizing manner. The patents on this apparatus have been dedicated to public use.

OVEN BIRDS, birds belonging to the subfamily *Furnarinae*, in the family *Dendrocolaptidae* (tree-creepers). The oven-birds are found in tropical America and Argentina and are all of small size and feed upon seeds, fruits and insects. They walk on the ground with great ease. Some of these forms appear to frequent the shore, where they feed upon small mollusks and crabs. They are said to be exceedingly tame: the best-known species (*Furnarius fulginosus*) haunting village gardens and seeming to court the company of man. Their popular name is derived from the form of the nest which they construct. It is built of straws and dried leaves mixed with clay and resembles an oven in its conical shape, being about eight inches in diameter. The walls are about an inch thick. The aperture exists at the side and the interior is divided by a partition-wall into two rooms, in the inner of which the eggs are deposited. The nest is placed on a high and generally exposed site. Other species make strange nests of various kinds, one being a massive cylinder of mud.

In the United States the name oven-bird is commonly given to the golden-crowned water-thrush, a small terrestrial warbler, which builds a covered nest on the ground in the woods. See **WATER-THRUSH**.

OVENSHINE, Samuel, military officer: b. Pennsylvania, 2 April 1843. He entered the Union army at the outbreak of the Civil War in 1861 and was commissioned 2d lieutenant, rising to the rank of captain in 1864. He continued in the army after the close of the War

and in 1898 was appointed brigadier-general of volunteers and in 1899 was made brigadier-general of regulars and in the same year commanded a brigade in the Philippine Islands. He retired after over 30 years' active service.

OVERBECK, ō'vēr-bĕk, Johann Friedrich, German painter: b. Lübeck, 4 July 1789; d. Rome, 12 Nov. 1869. He became very early imbued with the spirit of romanticism (q.v.) and on commencing his art studies at Vienna 1806, found at the Academy congenial friends in Pforr, Vogel and others of the same school. Their devotion to the old Flemish and Italian masters met with much criticism and opposition in the Academy and in 1810 Overbeck who was called by his father "the young German Raphael," left for Rome where he associated himself with Schadow in the development of their common ideals. In the following year Cornelius joined their company and a little later Philip Veit and J. Schorr united with them in the formation of an artistic brotherhood. Their headquarters was the studio in the monastery of Saint Isidore, and they professed their object to be the religious and moral in art. Their aim was the revival of German art on the lines quattrocentists of Italy. They were first known as the Monastic Brotherhood of Saint Isidore and later as Nazarenes (q.v.), of whom Overbeck was the acknowledged leader. The first important work which they executed was the history of Joseph in the 'Casa Zuccara' near the Trinità de'Monti, then occupied by Consul-General Bartholdy. Overbeck painted there the 'Selling of Joseph' (1816), the cartoon for which is now in the city museum at Frankfurt. He also contributed 'The Seven Lean Years' (1851). Five of the frescoes illustrating Tasso's 'Jerusalem Delivered' in the villa of the Marchioness Massimi are also his work. He decorated with frescoes the church of Santa Maria at Assisi, and among his numerous oil paintings examples are to be found in Saint Martin's Church, Lübeck, the New Picture Gallery at Munich and the Berlin National Gallery. The last remarkable pictures which he executed were the 'Coronation of the Virgin,' now in the City of Mexico; and 'Jesus Descending from the Hill of Nazareth,' in the museum of Antwerp. All his work is distinguished by refined drawing, noble composition and a profound spirit of devotion, and these characterize the 40 well-known designs illustrating New Testament history, all of which have been engraved, and some of them printed in colors. Among the founders of the German Romantic School of painting Overbeck is the only one who kept unflinchingly to the original program of the Nazarenes. His productions are of rare excellence in the perfection of the grouping, in directness and simplicity of expression and a purity of outline which recalls Perugina and the earlier style of Raphael. A sincere religious spirit pervades every conception, and the corporeal is dominated by the spiritual in all his refined ascetic forms and faces. It would seem that his love of the ecclesiastical and monastic type of character, and his enthusiasm for mediævalism, had much influence in his conversion to the Roman Catholic Church (1813). He exercised great influence as professor in the Academy of San Luca at Rome, and his most noted pupils were S. Steinle and

Führich. Consult 'Lives' by Atkinson and by Howitt; Dohmes, 'Kunst und Künstler des 19. Jahrhunderts' (1883-95).

OVERBURY, ȏ'vēr-bēr-ī, **SIR Thomas**, English author: b. Ilmington parish, Warwickshire, 1581; d. London, 15 Sept. 1613. He was graduated at Queen's College, Oxford, and was called to the bar of the Middle Temple, and was knighted in 1608. He became adviser to the Earl of Rochester, then Robert Carr, at the court of James I, and provoked the anger of the Countess of Essex by endeavoring to dissuade his friend from marrying her. Rochester had the address to procure the imprisonment of Overbury in the Tower of London, where he was slowly poisoned by secret agents and at the end of the year Rochester married the countess. Three years later it became apparent that there had been foul play in Overbury's death: four subsidiary agents were condemned and executed, but Carr (then Earl of Somerset) and Lady Essex, though convicted and imprisoned until 1621, were finally pardoned. Overbury was highly cultured and was credited by Jonson with the introduction into court circles of intelligent appreciation of literature and art. His best remembered work is his 'Characters,' published as an appendix to his poem 'A Wife' (1614). Selections from 'Characters' were issued in *The Cornhill Booklet* for August 1901. His works were edited by Rimbault in 1856.

OVERCOMERS, a name commonly applied to a religious society originating in Chicago in the latter part of the 19th century, but now dwelling at Jerusalem, where they style themselves the "American Colony in Jerusalem." They have all property in common and have abolished among themselves the institution of marriage. They profess to have discovered the true interpretation of the Bible, by which all nations are to be brought into liberty, righteousness and love.

OVERFLOW BUG, the carabid beetle (*Platynus maculicollis*), common in California. At times its numbers increase at such a rate that it becomes a nuisance, but it is very beneficial as it destroys several species more nefarious.

OVERLAND ROUTE, a popular term applied to the route to California as distinguished from the route via the Isthmus of Panama. Also a term first used for the route from Europe to India via Egypt, the desert and Suez. It was in contradistinction to the Cape route which was by water only. It became more applicable in 1837, when the route was across the European continent by Marseilles; in 1845, when that by Trieste followed; and in 1872, when that via the Mount Cenis tunnel and Brindisi came into use. It also came into use in 1899 for the land route from Victoria, B. C., to the Alaskan gold fields.

OVERLAP. See UNCONFORMITY WITH OVERLAP.

OVERMAN, Lee Slater, American legislator: b. Salisbury, N. C., 1854. In 1874 he was graduated at Trinity College, North Carolina; was for some time employed as a teacher; and was private secretary to governors Vance and Jarvis. In 1878 he was admitted to the bar and began his law practice at Salisbury. He was

elected to the lower house of the North Carolina legislature in 1883, 1887, 1893 and 1900, and was chosen speaker in 1893. He was president of the State Democratic Convention in 1900 and in 1903 was elected to the United States Senate. Senator Overman was re-elected in 1909 and 1914; became chairman of the Rules Committee in 1913 and was also active as a member of the Judiciary Committee.

OVERSEAS NEWS SERVICE, a German news association which, in 1917, was purchased by a syndicate representing the German government and partially merged with the Wolff Bureau, which had also come under the control of the government. See PRESS ASSOCIATIONS and WOLFF AGENCY.

OVERSEERS OF THE POOR, in the United States, are county officers whose duty is to make provision for the maintenance of the poor of the county. In New York and a few other States this duty devolves upon the county supervisors. In Great Britain overseers are public officers appointed annually in every urban district for the purpose of raising by rate on the inhabitants the sums necessary for the relief of the poor, and applying such sums to their relief. They have been appointed since the time of Queen Elizabeth by the important poor law act then passed. Their appointment must take place on the 25th of March, or within a fortnight thereafter. In urban districts the justices make the appointments, unless the local government board transfers it to the local council. In London the councils of the metropolitan boroughs act as overseers. Peers, members of Parliament, clergymen, barristers, attorneys, doctors, military and naval officers and others whose avocations require continual personal attendance are exempt from serving the office. All who are not exempted by some statute and even women are liable to be appointed, and it is an indictable misdemeanor to refuse without good cause to serve when duly appointed. The office is gratuitous, and no person is to be appointed overseer who is directly or indirectly concerned in any contract for the supply of any goods, materials or provisions for the workhouse or for the relief of the poor of the district.

OVERSKOU, Thomas, Danish dramatist: b. Copenhagen, 11 Oct. 1798; d. 1873. When only 20 years of age he had become possessed of some dramatic talent and began to play minor parts. In 1842 he retired with a pension; in 1849 he became manager under Herberg, whom he succeeded in 1856, but in 1858 retired. His first play, '1826,' written in 1826, was a pronounced failure, but his other dramas were of considerable merit and were successfully staged. The most noteworthy of these were 'Oestergade og Vestergade' and 'Capriciosa.' He also published 'Den danske Skueplads, i dens Historie, fra dens Begyndelse til vor Tid' (History of the Danish Theatre, 7 vols., 1854-76). His original comedies were published in five volumes (1851-52).

OVERSTONE, Samuel Jones Loyd, **BARON**, English financier: b. London, England, 25 Sept. 1796; d. there, 17 Nov. 1883. He was graduated from Cambridge in 1818, entered the banking-house of his father (who had been a Welsh dissenting minister) and became its head

before its consolidation with the London and Westminster Bank. He was a member of Parliament for Hythe in 1819–26 and became a recognized authority on questions of finance. He strenuously opposed the introduction of limited liability and greatly aided in defeating the proposal for a decimal currency, but did not engage in politics after 1833, when he was defeated as candidate to Parliament for Manchester. He was the author of many valuable tracts on questions of finance, and the Bank Act of 1844 was directly due to the influence of his writings. In 1850 he was created Baron Overstone and Fotheringhay.

OVERT, *in law*, evident, undisguised; an overt act signifies an act which may be clearly proved and was manifestly intended. The mere contemplation of or intention to commit a crime is not an act amenable to human laws; but the moment an overt act is manifest the person so acting is amenable to the laws. In the United States two witnesses must bear testimony to the same overt act or a confession be made in open court in order to secure conviction.

OVERTHRUST. See **FAULT**.

OVERTON, James Bertram, American plant physiologist; b. Richmond, Mich., 23 Dec. 1869. He was graduated at the University of Michigan in 1894 and in 1901 took the degree of D.Ph. at the University of Chicago. In 1894–95 he was assistant principal of the high school at Black River Falls, Wis., in 1894–95 senior master in mathematics at Saint John's Military Academy, Delafield, Wis., in 1895–98 and in 1901 assistant in botany at the University of Chicago. From 1901 to 1904 Mr. Overton was professor of biology at Illinois College; in 1904–07 was instructor in botany; in 1907–12 assistant professor; in 1912–15 associate professor of plant physiology, and after 1915 professor at the University of Wisconsin. He is member of several scientific societies, American and foreign.

OVERTON, John Henry, English Anglican Church historian; b. Louth, Lincolnshire, 4 Jan. 1835; d. Gumley, Lincolnshire, 17 Sept. 1903. He was educated at Lincoln College, Oxford, took orders in the English Church and was curate of Quedgeley 1858–60; vicar of Legbourne 1860–83; rector of Epworth 1883–99; and rector of Gumley from 1898. He became canon of Lincoln Cathedral in 1879; canon of Peterborough in 1903, and was Birbeck lecturer on ecclesiastical history at Trinity College, Cambridge, 1902–03. He was the author of 'The English Church in the 18th Century' with C. J. Abbey; 'William Law: Non-juror and Mystic'; 'Life in the English Church 1660–1714'; 'Life of Christopher Wordsworth, Bishop of Lincoln'; 'Evangelical Revival in the 18th Century'; 'John Wesley'; 'The English Church in the 19th Century 1880–1833'; 'The Anglican Revival'; 'The Nonjurors'; and (posthumously) 'Some Post-Reformation Saints'; and 'History of the English Church from the Accession of George I to the End of the 18th century.'

OVERTON, Richard, a British pamphleteer flourishing in the first half of the 17th century, probably from about 1630–65. He spent part of his early life in Holland, but upon his return about the time when the Long Parlia-

ment opened commenced publishing anonymous attacks on the bishops. He next turned to theology and wrote a tract on 'Man's Mortality,' which excited much comment, and soon following the publication of this tract a small sect arose known as 'Soul Sleepers,' who adopted a modified form of his doctrines as portrayed in this tract. This was suppressed by the House of Commons and Overton branded a heretic. He then began a violent attack on the clergy in a series of pamphlets for which he was arrested, but his authorship could not be proven and the charge against him dropped. In 1646 he became involved with Lilburne in his case against the Lords and was imprisoned, but found support in the army and after a year of confinement was released. His imprisonment had not diminished his democratic zeal, for he at once took up with the London levelers and was one of those who presented to Fairfax the 'Plea for Common Right and Freedom.' On 28 March 1649 he was again arrested and sent to the Tower, and even while there managed to issue a 'Defiance' to the government, but through lack of sufficient evidence he was released on 8 November. In 1655 he became implicated in the projected uprising of the levelers, fled to France, obtained a commission from Charles II, and some months later returned to England to bring about an insurrection. Of his later history little is known except that he was imprisoned in December 1659 and again on 22 Oct. 1663, probably for attacks on the government of Charles II. The most important of his numerous works are 'New Lambeth Fair Newly Consecrated, etc.' (1642); 'Articles of High Treason Exhibited Against Cheapside Cross' (1642); 'Man's Mortality' (1643); 'The Arraignment of Mr. Persecution' (1645); 'An Alarm to the House of Lords' (1646); 'The Outcries of the Oppressed Commons' (1647); 'A Picture of the Council of State' (1649); 'Overton's Defiance of Act of Pardon' (1649); 'The Baiting of the Great Bull of Bashan' (1649), etc.

OVERTURE, *in music*, an introductory symphony, chiefly used to precede great musical compositions, as oratorios and operas. The Germans have composed overtures for poetical works, as Beethoven's overture to Goethe's 'Egmont.' Overtures are often played independently of the work for which they were written, as at the beginning of concerts; but their highest office is to convey to the intelligent lover of music the whole character of the following piece or to concentrate its chief musical ideas so as to give a sort of outline of it in instrumental music. The latter mode of composing overtures was first conceived by the French, and such is the character of the overtures of their great composers, among whom may be classed Cherubini. Carl Maria von Weber, in the overtures to the 'Freischütz' and 'Oberon,' in which the general character of the following piece is given, has observed this rule, which did not exist when Mozart composed his admirable overtures to 'Figaro' and 'Don Juan.' In the oldest overtures the fugue was the chief part, preceded by a *grave* and closing in the dominant. Another form came into vogue at a later period — three musical parts, in different movements — an *allegro*, an *andante* and again an *allegro* or *presto*, were united. At present the

most usual form is a brilliant and passionate *allegro*, preceded by a short, solemn passage. See also *PRELUDE*.

OVID, Publius Ovidius Naso, Roman poet: b. Sulmo (Sulmona), high among the Apennines, almost due east of Rome, 20 March 43 B.C.; d. Tomi (Kustendje), on the Black Sea, south of the mouth of the Danube, 17 or 18 A.D. His family belonged to the class of wealthy landowners, and he and his brother, who died, however, in early manhood, were educated, as was usual, for an official career. In the short sketch of his life given in 'Tristia,' iv, 10, he tells us that, despite his best efforts, all that he wrote took metrical form, and although, to please his father, he persevered and actually filled several minor offices, poetry soon claimed him for her own. Twice married and soon divorced, he took as his third wife a lady of the great Fabian house, who remained faithful to him in his exile, though neither she nor his daughter shared it with him. His own gifted and winning personality, coupled with an ungrudging admiration of the genius of others, won for him the friendship of all the poets of his time, especially of Propertius, and of Tibullus, whose untimely death he laments in one of his few poems of true pathos ('Amores,' iii, 9). With the poet Æmilius Macer, Virgil's friend, he spent more than a year abroad, visiting Athens, the famous coast towns of Asia Minor, and especially Sicily, by whose beautiful scenery and legendary associations he was completely captivated. His works show the influence of his travels, though most of the material is supplied by his multifarious reading.

During the reign of Augustus, Rome became for the first time a really imperial city, and the external splendor of the capital was matched by the distinction of its fashionable society. All the arts of life were called into play to lend a finer polish and a keener zest to social intercourse. Wit and good manners took the place of religion and morality. Of this gay and cultivated society, with its worship of the senses, its cynical worldly wisdom and its love of brilliant rhetoric, Ovid is a typical member. In the first period of his literary activity he treats almost exclusively of love, regarded always as desire, never, at least on the part of the man, as devotion. To this time belong: (1) 'Amores,' in three books, poems for the most part associated with a certain Corinna. (2) 'Heroides,' 21 love letters written by women of the Heroic Age. The first 15 are to their husbands or lovers. The last six—Paris to Helen, Leander to Hero, Acontius to Cydippe and the replies in each case—are now regarded as probably Ovidian though their authorship has long been a matter of dispute. (3) 'De Medicamine Faciei,' on the beautifying of the face. (4) 'Ars Amatoria,' in three books, regarded by Macaulay as Ovid's greatest and most characteristic work. "Perhaps the most immoral poem ever written." (5) 'Remedia Amoris,' a companion to the 'Ars,' but in no way comparable with it. He wrote also a tragedy, 'Medea,' much praised by ancient critics, which has not come down to us.

About the beginning of the Christian era he undertook the composition of two works of far wider scope and somewhat different character, the 'Metamorphoses' and the 'Fasti.' The first of these, in 15 books, is deservedly his

best-known work. The stories of the Greek mythology, involving an amazing variety of transformations from primæval chaos to the change of Julius Cæsar into a star, are retold with inimitable grace and liveliness, and most ingeniously linked together, like the tales of 'The Arabian Nights,' into an unbroken series. The book has had an immense influence upon modern literature in England notably on Marlowe, Spenser, Shakespeare, Milton and Dryden, and was a storehouse of subjects for the painters of the Renaissance. The 'Fasti,' originally in 12 books, of which, however, the last six were never completed and published, is an account of the astronomical phenomena and the Roman festivals of the first six months of the year. The inquiry into the origin of the feasts and their ceremonies gives occasion for some entertaining stories from Roman mythology and early history.

Ovid was still engaged upon these works when, toward the end of the year 8 A.D., an imperial edict ordered him to leave Rome on a specified day and proceed to Tomi, on the desolate shores of the Euxine. His books were excluded from the three public libraries of Rome, and, while his property was not confiscated, no hope of recall was held out. The reason for his banishment is still a mystery. In the poems of exile, Ovid repeatedly ascribes his fate to two causes, his poetry (*carmen*) especially the 'Ars Amatoria,' and a "mistake" (*error*) not "guilt" (*scelus*), for which his eyes were responsible. But he steadily refuses to state the nature of this *error*, on the ground that he is unwilling to pain Augustus a second time. The 'Art of Love,' which had been published nearly 10 years before, while it may well have been the ultimate cause, could hardly have been the actual occasion of the edict, and it has been thought not improbable that he was involved in the intrigue of the younger Julia, the emperor's granddaughter, with Silanus, a scandal which was coincident with Ovid's ruin. He wrote at Tomi 'Ibis,' a learned invective against an enemy at Rome, and a fragment of a poem on fish, 'Halieutica,' also eulogies of Augustus and Tiberius which have not come down to us. The loss of the poem on Augustus is especially to be regretted, as it was written in the native Getic dialect. But the two important productions of these melancholy years are the five books of 'Tristia' and the four books of 'Epistolæ ex Ponto.' These elegies are addressed to his wife, to his friends, to Augustus, and give expression to the poignant sorrows of his present lot and his passionate longing for home. Boissier calls his appeals to Augustus a "delire d'adulation." But it was all in vain, and he died a few years after the accession of Tiberius, broken hearted, though much beloved by the people of Tomi.

Ovid's work is characterized by remarkable smoothness and variety of expression, by the liveliest fancy, and a positive genius for graphic description, but he wrote with too great facility to learn the lesson of self-restraint. Nevertheless he is an incomparable story teller, and would to-day be famous for his mastery of the technic of the short story. With the exception of the 'Metamorphoses' and the 'Halieutica' which are written in hexameters, all his poetry is cast in the form of the elegiac distich, and this he brought to such perfection

that the Ovidian couplet became the model for all modern work in this measure. See **METAMORPHOSES**.

Bibliography.—The best text is that of Merkel, revised by Ehwald (Leipzig 1889-94). The 'Amores' were translated into English verse by Christopher Marlowe and (in part) by Dryden, the 'Ars Amatoria' (in part) by Congreve and by Dryden, the 'Heroides' (in part) by Dryden, Book I of the 'Tristia' by Arden (New York 1821). Palmer's edition of the 'Heroides' with the Greek translation and commentary of Planudes was, issued in 1898. Garth gathered into one volume (1st ed., London 1810) versions of the 'Metamorphoses' by various hands, Dryden, Addison, Congreve, Pope, Rowe, Gay and others, including himself. Golding's famous translation first published 1567, was reprinted in London 1904. Two excellent translations have recently appeared in the Loeb Classical Library, 'Heroides and Amores' by Showerman (New York 1914) and 'Metamorphoses' by Miller (2 vols., 1916). Consult Nageotte, 'Ovide, sa vie, ses œuvres' (Dijon 1872); Sellar, 'Horace and the Elegiac Poets' (Oxford 1892); Boissier, 'L'Opposition sous les Césars' (Paris 1892); Lafaye, 'Les Métamorphoses d'Ovide et leur modèles grecs' (Paris 1904); Butler, 'Post-Augustan Poetry' (Oxford 1909); Rand, 'Ovid and the Spirit of Metamorphosis' (in 'Harvard Essays on Classical Subjects,' Boston 1912).

NELSON G. MCCREA,
Anthon Professor of the Latin Language and
Literature, Columbia University.

OVIEDO, ò-vē-á'thō, Juan Antonio, South American clergyman: b. New Granada, 25 June 1670; d. Mexico City, 2 April 1757. He was graduated from the University of Guatemala and shortly afterward became professor of philosophy there; then for some time taught philosophy in Mexico and theology in Guatemala; became procurator at Rome and Madrid; then was appointed rector of Mexico and was twice provincial of the Jesuits of Mexico. His writings are mainly historico-religious, dealing mostly with the ecclesiastical history of Mexico and California.

OVIEDO, Spain, (1) a town in the Asturias, capital of a province of the same name, 230 miles northwest of Madrid. It is walled, and has clean but irregular streets. The Gothic cathedral (a part of which dates from the 9th century), university with 900 students, meteorological observatory, courthouse and hospital are the chief buildings. There are manufactures of firearms, explosives and ordnance. In 1809 Oviedo was given up to pillage for three days by Ney. Pop. about 53,269. (.) The province, area, 4,205 square miles, is situated on the Bay of Biscay, and bounded by the provinces of Santander, Leon and Lugo. It has a wild and stormy coast, and a mountainous interior better adapted for pasture than agriculture. Great numbers of cattle, goats and swine are raised and its horses are celebrated; linens, woolens, leather, etc., are manufactured, and coal is exported. Pop. 706,816.

OVIEDO Y VALDEZ, ē vāl-dā'h', Gonzalo Fernandez de, Spanish historian: b. Madrid, 1478; d. Valladolid, 1557. In 1513 he received a government appointment in the newly-

discovered island of Hispaniola, and with few intervals spent the rest of his life there. Named by Charles V historiographer of the Indies, he wrote his 'Sumario de la Historia General y Natural de las Indias Occidentales' (1535 et seq. in 21 volumes). He wrote also 'Quinquagenas,' so entitled from its consisting of 50 dialogues, in which the author is the chief interlocutor, and fragmentary chronicles of Ferdinand and Isabel and Charles V. Much other work of his is still in manuscript.

OVI PAROUS ANIMALS are those that produce their young by eggs hatched after exclusion from the body of the parent, the development of the embryo thus not taking place within the parent's body. Except the mammalia, all animals are either oviparous or ovoviviparous; the latter mode—not essentially different from the former—being comparatively rare. Even those invertebrate animals which multiply by gemmation and division have also a true reproduction by *ova*.

OVIPOSITOR, an organ developed in relation to the orifice of the genital ducts of female insects, whose normal function is to place the fertilized egg in a position most suitable to its proper development. When typically developed the ovipositor consists of three pairs of stiff or membranous unjointed styles or gonapophyses, of which the anterior or lowermost closely ensheathes the other two. The three pairs together form a tube into the base of which the oviduct opens and along which the eggs are conducted to the situation selected for their deposition. The homology of these styles is not fully settled, but the generally accepted and best supported view is that they represent the embryonic appendages of the seventh, eighth and ninth abdominal segments, from which they are directly developed in at least some cases. In the entire orders of *Lepidoptera*, *Coleoptera* and *Diptera*, as well as in many representatives of other orders, no true ovipositor is developed. In such cases the terminal segments of the abdomen may form a retractile and protractile tube serving as an egg-conductor. The *Orthoptera*, *Odonata*, *Hymenoptera* and *Hemiptera* exhibit the organ in its highest state of development, and variously modified to meet various conditions. In the locusts it has the form of a stout sickle-blade, permanently exerted, and efficient in splitting plant tissues for the reception of the eggs. The sawflies have the margin of the outer sheath serrated for cutting slits into leaves, etc., while the cicades completely shatter twigs by the power of their ovipositors. Some of the ichneumon flies (q.v.) have ovipositors remarkably adapted to their parasitic habits; in the long-tailed ichneumonfly for example, the organ is filamentous and so long and powerful that it is capable of penetrating the solid wood of tree trunks to a depth of several inches, reaching and depositing eggs within the burrows of woodborers on which the ichneumon-fly larvæ subsist.

The most remarkable of all modifications of the ovipositor, however, is found among the ants, bees and wasps, in most of which it becomes a most efficient and beautifully constructed poisoning apparatus or sting, which consequently is possessed by the females alone. The sting, like other ovipositors, consists of three pairs of styles, but the middle pair are

united into a single barbed piece grooved on the ventral side, and partly ensheathing the inner pair of very acute piercing darts. The outer pair form a protecting sheath to the sting proper. Within the abdomen is a tubular venom gland, with a reservoir and duct opening into the base of the grooved piece. When in operation the latter and the two darts work alternately in and out, penetrating deeper and deeper into the wound into which they conduct the venom. The male genital armature of insects is derived from essentially the same embryonic parts as the ovipositor and sting of the female, but never reaches the same structural complexity and serves solely as a clasp organ during copulation. Consult Packard, 'Text-book of Entomology' (1898).

OVIS, a genus of the family *Bovidae* and subfamily *Ovinæ*, including the sheep (q.v.).

OVULE, an outgrowth of the carpel of a plant where, by fertilization with pollen, a seed is formed. It is the homologue of the macrosporangium of the pteridophytes (see *FERNS AND FERN ALLIES*), and contains the embryo-sac or *macrospore*. The ovule consists of the *nucellus*, which is surrounded by one or two *integuments*, and is attached to the carpel by a stalk known as the *funiculus*, at a place called a *placenta*. If the nucellus and funiculus are in a line, the ovule is *atropous*; if the nucellus is bent back on the funiculus it is *anatropous*; and if the nucellus is itself bent the ovule is *campylotropous*. The ovules are always enclosed among the angiosperms in the cavity of the ovary, or seed-producing organ. They are developed as a rule from the margin of the carpels, but several exceptional modes of development exist. The gymnosperms (q.v.) have no ovaries. See *SEED*.

OVUM, an egg. See *EMBRYOLOGY*; *EGG*.

OWARI, ō-wā'rē, or **BISHIU**, bē'shoo, Japan, a densely peopled province of the empire, on the island of Hondo, south of Mino, west of Mikawa, east of Omi and Isé. Owari Bay lies on its southern border. The soil is very fertile and the province produces vast quantities of clay suitable for all grades of pottery and chinaware. Seto, near the capital, Nagoya, was the original home of ceramic art in Japan, being introduced thither from China in the 13th century. Enameling is also an important industry of the province.

OWATONNA, ō-wā-tōn'na, Minn., city, county-seat of Steele County, on the Straight River and on the Chicago and North Western; Chicago, Rock Island and Pacific and the Chicago, Milwaukee and Saint Paul railroads; about 65 miles south of Saint Paul. It was settled in 1855 and incorporated in 1865. It is in an agricultural region in which corn, wheat and nursery stock are important products. The chief manufactures are dairy products, flour, foundry and machine-shop products, soap, butter tubs, churns, automobiles, carriages, seeders, engines and fanning mills. The prominent buildings are the courthouse, two opera-houses, city hospital, the church and school buildings. There are three parks, four steel bridges and a large number of fine residences. The educational institutions are the State School for Dependent and Neglected Children, the Pillsbury Academy, Sacred Heart

Academy, public and parish schools and a public library which contains several thousand volumes. The government is vested in a mayor who holds office two years and a council. The city owns and operates the waterworks. Pop. (1920) 7,252.

OWEGO, ō-wē'gō, N. Y. ('place where the valley opens'), village, county-seat of Tioga County, on the Susquehanna River at the mouth of the Owego Creek, and on the Delaware, Lackawanna and Western, the Lehigh Valley and the Erie railroads, about 30 miles east of Elmira and 20 miles west of Binghamton. It was settled in 1785 by James and Robert McMasters and others. It was chartered as a village in 1827. An Indian village, on the site of the present Owego, was destroyed by General Clinton in 1779. It is in a farming section, but has considerable manufacturing interests. It contains steel bridge works, mica works, leather glove factory, wagon works, cigar factory, saddlery, silk glove factory, piano factory and other manufacturing industries. Owego has considerable trade in lumber, farm products and in its own manufactures. The educational institutions are the Owego Free Academy, union and graded schools, one parish school and the Coburn Free Library. There are seven churches. The three banks have a capital of over \$200,000; the annual business exceeds \$800,000. The government is vested in a president and six trustees; three of the trustees are chosen each year by popular vote. It is also a favorite summer resort. There is a colored population of about 10 per cent of the whole. Pop. 4,147.

OWEN, ō'en, David Dale, American geologist: b. New Lanark, Scotland, 24 June 1807; d. New Harmony, Ind., 13 Nov. 1860. He was educated at Hofwyl, Switzerland, and accompanied one of his brothers in 1827 to the United States, his father being the author of the socialistic undertaking at New Harmony. He made a special study of geology and natural science, and his investigations took him over a large portion of Indiana and Iowa. He made a government geological survey of Iowa, Wisconsin and Minnesota, beginning in 1848, and 1852-57 was engaged in a geological survey of Kentucky. He was appointed State geologist of Kansas in 1857-59. Among his publications are reports of his surveys of Indiana and Arkansas (1858-60).

OWEN, Sir Douglas, English barrister: b. 1850. He received a private education and also attended King's College School. He acquired an international reputation as an expert on maritime insurance and transportation; he has served on many government committees in connection with maritime affairs, and lectured at the London School of Economics and the Royal Naval War colleges. In 1914 he became chairman of the Advisory Committee of the State War Risks Insurance Office. He was knighted in 1915. His publications are 'Digest of the Law of Marine Insurance'; 'Declaration of War; a Survey of the Position of Belligerents and Neutrals in Maritime War'; 'Ocean Trade and Shipping'; 'London, the Port of the Empire'; 'Ports and Docks.'

OWEN, John, English epigrammatist: b. Llanarmon, Wales, 1560; d. 1622. He re-

ceived his education at Winchester School and at Oxford; became Fellow of New College in 1584 and in 1591-94 taught at Trelleck in Monmouthshire. He was made headmaster of the new free school at Warwick in 1594. Owen is but remembered for his Latin epigrams. Consult the collection 'Johannis Audoeni Epigrammatur Libri Tres' (1606) and the English translations of Hayman (1628); Harflete (1658); Peck (1659); Harvey (1678) and the French of Renouard (Paris 1794).

OWEN, John, English Non-Conformist clergyman: b. Stadhampton, Oxfordshire, England, 1616; d. Ealing, Middlesex, England, 24 Aug. 1683. He was educated at Oxford which he left rather than submit to Land's new statutes and early espoused the Parliamentary cause in the Civil War. In 1642-46 he was pastor at Fordham, Essex, from which he was ejected; and in the latter year took charge of a Presbyterian congregation at Coggeshall, Essex, and there introduced independent church government. He was appointed private chaplain to Cromwell in 1649, and in 1651 was dean of Christ Church, Oxford, where he was vice-chancellor of the university in 1652-57. Losing favor with Cromwell, he was removed from his office as dean in 1660, and though offered a parish in Boston, Mass., in 1663, and the presidency of Harvard College in 1670, declined both and was pastor of an independent church in London. In spite of the act of uniformity, he was tolerated and his preaching permitted. He devoted much time to literary work. He was a stout champion of the fullest religious liberty, and one of the most celebrated of Puritan divines. His most notable work was an 'Exposition of the Epistle to the Hebrews' (1668-84). His collected works were published in Edinburgh in 1850-55 and in Philadelphia in 1865-69. Consult 'Life' by W. Orme (1820) and Moffatt, 'The Golden Book of John Owen' (1904).

OWEN, Mary Alicia, American author: b. Saint Joseph, Mo., 29 Jan. 1858. She was educated at private schools and at Vassar College and turned her attention to the study of Indian lore; her discoveries in Voodoo magic were important and she was admitted to tribal membership with the Indians and to their secret societies. She also made a study of the gypsies, and published 'Voodoo Tales'; 'Oracles and Witches'; 'Folk-Lore of the Musquakie Indians'; 'Prairie Tribes of the Algonquin Indians'; 'The Sacred Council Hills'; 'Rain Gods of the American Indians'; besides delivering many lectures on these subjects. She is president of the Missouri Folk-Lore Society and a distinguished member of other folklore and scientific societies.

OWEN, Sir Richard, English naturalist: b. Lancaster, 20 July 1804; d. Richmond Park, 18 Dec. 1892. He studied at the University of Edinburgh, began practice in London as a surgeon in 1826, became lecturer in comparative anatomy at Saint Bartholomew's Hospital in 1829, later was conservator of the Hunterian Museum of the Royal College of Surgeons until 1856, and in 1836-56 was first Hunterian professor of comparative anatomy and physiology. In 1838 he received the Wollaston gold medal of the Geological Society, and in 1840 became the first president of the Microscopical Society.

From 1856 to 1883 he was superintendent of the natural history collections of the British Museum. In 1887 he obtained the removal of these collections from the museum and their establishment at South Kensington as a museum of natural history. He was the first Rede lecturer at Cambridge in 1859, and received numerous foreign distinctions, including the decorations of many orders and the Cuvier prize (1857). In 1857 he assisted David Livingstone (q.v.) in the preparation of the latter's 'Missionary Travels and Researches in South Africa,' and in 1861 published an edition of the posthumous papers of John Hunter. Among the more important of his own works were 'Odontology' (1840-45); 'Comparative Anatomy and Physiology of Invertebrates' (1843); 'British Fossil Mammals and Birds' (1846); 'On the Anatomy of Invertebrates' (1866-68); 'Fossil Remains of Extinct Mammals of Australia' (1877-8); 'Extinct Wingless Birds of New Zealand' (1879); and 'Experimental Physiology' (1892). By 1856 he had won recognition as the leading anatomist and palaeontologist of his time. He was created K.C.B. in 1854. His scientific labors were extensive and continuous, and he was an active and often bitter controversialist. He was with Cuvier a pioneer in vertebrate palaeontology, and made to the study many important contributions, including prominently a paper on 'Archæopteryx' (1863). His discoveries also were numerous. He was among the first to work toward a concise nomenclature in anatomy and to originate the theory of germ plasm. Consult 'Life' by his grandson (1894).

OWEN, Robert, English socialist: b. Newtown, Montgomeryshire, North Wales, 14 May 1771; d. there, 17 Nov. 1858. He established a small cotton-spinning works at Manchester, and later became known as a successful manager of large mills, and was the first to use Sea Island cotton. In 1794-95 he organized the Chorlton Twist Company, which operated the New Lanark mills, near the falls of Clyde, founded by his father-in-law, David Dale. There were 1,300 employees at the latter, nearly 500 being pauper children. As illustrating the thorough-going nature of the social experiment here made, in 1806, during the American embargo, the mills were stopped for four months, but the employees were paid full wages. In 1814 a new company was established to operate the mills, as the old partners were hostile to Owen's social schemes. This included the names of William Allen, Joseph Fox, Jeremy Bentham and other noted philanthropists and reformers, and was organized on the principle "that all profits beyond 5 per cent per annum on the capital invested shall be laid aside for the religious, educational and moral improvement of the workers and of the community at large." The employment of young children was stopped, a new system of education established, the houses improved and insurance funds established; and the community of New Lanark became noted for the prosperity of its people. In 1813 Owen published 'New Views of Society, or Essays upon the Formation of Human Character,' and in 1826-44 a 'Book of the New Moral World,' in which he advanced and developed his socialistic views, insisting upon an absolute equality among men. In 1817 he presented a report to a Parliamentary

committee on the causes of poverty and means of avoiding it. In 1829 he gave up the management of the Lanark Mills, and devoted his time and entire fortune to the propagation of his socialistic doctrines. He set up two social communities on his own plan, one at Orbiston in Lanarkshire, another at New Harmony, Ind. (1824-28). They proved signal failures, the latter costing him \$200,000. In his later years he became a believer in Spiritualism. He is regarded as the founder of infant schools and of Socialism in England; many of his followers were active in the Chartist movement. His chief conclusions were that there is something fundamentally wrong in all religions—a conclusion he first reached when 10 years old; and that "of all truths the most important is that the character of man is formed *for* and not *by* him."

Consult his own incomplete biography (1857-58); Holyoake, 'Life and Last Days of Robert Owen' (1871); Jones, 'Life, Times and Labours of Robert Owen' (1890); Podmore, 'Life of Owen' (1906).

OWEN, Robert Dale, American social reformer: b. Glasgow, Scotland, 9 Nov. 1801; d. Lake George, 17 June 1877. He came to the United States in 1824 with Robert Owen (q.v.). In 1826 he received from Fanny Wright 860 acres of unimproved land at Nashoba, near Memphis, Tenn., for the purpose of establishing under white direction a settlement of liberated negroes. This scheme failed. In 1827 he established at New York with Fanny Wright *The Free Inquirer*, a socialistic, agnostic and Malthusian publication. In 1832 he returned to Indiana, where in 1835 he was elected to the legislature as a Democrat. He was chosen to Congress in 1843 and 1845. A measure concerning the Oregon boundary, introduced by him in 1844, became the basis of the settlement of 1846. He was prominent in the founding of the Smithsonian Institution (1845) and in the remodeling of the Indiana constitution (1850). In 1853 he was made *chargé d'affaires* at Naples, in 1855 Minister. After his return (1858) he was active as an abolitionist. He was, at least in later days, a firm believer in Spiritualism, and in this connection were written some of his most interesting works, such as, 'Foot-prints on the Boundary of Another World' (1859), and 'Debatable Land between this World and the Next' (1872). Others of his writings are 'The Personality of God and the Authority of the Bible' (1832), and 'Pocahontas: A Drama' (1837); 'Threading My Way' (1874), an autobiography covering the first 27 years of his career.

OWEN, Robert Latham, American lawyer and legislator: b. Lynchburg, Va., 6 Feb. 1856. Senator Owen began his career as a teacher in the Cherokee Orphan Asylum, but studied law and began practice in 1880. From 1881 to 1884 he was secretary of the board of education of the Cherokee Nation; and was owner and editor of the *Indian Chieftain* in 1884, and United States Indian Agent for the First Civilized Tribes, in 1885 to 1889. He organized the First National Bank of Muskogee, and was its president from 1890 to 1900, being also interested in banking, farming and cattle. He recovered from the United States government nearly \$9,000,000 for Choctaws, Chicasaws and

Cherokees. He was a member of the Democratic National Committee from 1892 to 1896. When Oklahoma was admitted to the Union Mr. Owen was elected United States senator from that State for the terms 1907-13 and 1913-19; re-elected in the latter year. He became chairman of the Committee on Banking and Currency in 1913, and was one of the framers of the Federal Reserve Act.

OWEN-GLASS CURRENCY BILL, better known as the Federal Reserve Act, was framed by Senator Robert Latham Owen of Oklahoma and Representative Carter Glass of Virginia in conjunction with Secretary of the Treasury McAdoo. The bill was introduced in both the Senate and the House on 27 June 1913. It passed the House 19 Sept. 1913, and the Senate, with amendments, 20 Dec. 1913; and was then sent to conference. It was thence reported with some changes back to the Congress, and was passed finally by the House 23 Dec. 1913, and by the Senate the following day; the President signing it immediately.

OWEN MEREDITH. See LYTTON, EDWARD ROBERT BULWER.

OWEN SOUND, Canada, town and county-seat of Gray County, Ontario, a port of entry at the mouth of Sydenham River, and at the head of its estuary (12 miles long) called Owen Sound, an outlet on Georgian Bay, Lake Huron. It is a terminal of branches of the Grand Trunk and Canadian Pacific railways, 122 miles northwest of Toronto, has one of the best harbors on the lakes, a dry dock, a large trade in grain and lumber and steamboat communication with all the principal lake ports. It has manufactures of agricultural and mill machinery, sewing machines, cement, bolts and screws and furniture, and lumber and flour mills, and large grain elevators. There are high and public schools and a library. Power is obtained from Eugenia Falls. Pop. 12,559. A United States consular agent is resident.

OWENS, o'enz, John Edward, American actor: b. Liverpool, England, 4 May 1824; d. near Towson, Md., 6 Dec. 1886. He made his first appearance as an actor in Philadelphia in 1841. In 1849 he was manager of the Baltimore Museum, and in 1852 opened Brougham's Lyceum in New York; later, manager of the Charles Street Theatre in Baltimore and afterward starred successfully for several seasons. In 1864-65 he played at Wallack's Theatre, New York, in 'Solon Shingle,' and in London. He starred in various stock companies and in 1882-83 made his last engagement in New York at Madison Square Theatre in 'Esmeralda.'

OWENS COLLEGE, Manchester, England, was established under the will of John Owens, a Manchester merchant, who died July 1846, and left about \$500,000 for the purpose of founding an institution for providing or aiding the means of instructing youths over 14 years of age, in such branches of learning and science as are now or may be hereafter taught in the English universities, subject to the immutable condition that no student, professor, etc., shall be required to make any declaration or submit to any test of their religious opinions, and that theological and religious subjects shall form no part of the teaching of the college. From 1851 to 1873 the college occupied a private

house, when it removed to a handsome Gothic building erected by public subscription. The success of the college led to a proposition, which received considerable ecclesiastical opposition, to incorporate a university, with several affiliated colleges located in different towns, but having its seat in Manchester. In 1880 Victoria University was instituted by royal charter, with power to grant degrees in arts, sciences and law, a supplemental charter, granted May 1883, giving power to grant degrees in medicine. Owens College was incorporated with Victoria University in 1904. University College, Liverpool, was incorporated with Victoria University from 1884 to 1903, and the Yorkshire College, Leeds, from 1887 to 1904. A women's college, under the direction of the professors of Owens College, is also affiliated, and Victoria University grants degrees or certificates to women. See MANCHESTER UNIVERSITY.

OWENS LAKE, a lake in Inyo County, southeastern California, east of Mount Whitney of the Sierra Nevadas, 18 miles long and 10 miles wide. It receives the waters of the Owens River (q.v.), but has no visible outlet, and its waters are very salt.

OWENS RIVER, a river of southeastern California, rises in the southern part of Mono County, flows southeast and then south, and empties into Owens Lake (q.v.); length, 175 miles. Its course is through a desert valley with the Sierra Nevada on the west and the Inyo Mountains on the east; its volume of water is considerably diminished during the summer season, some of its branches drying up entirely. A branch of the Southern Pacific Railroad parallels it for the greater part of its course.

OWENSBORO, ô'enz-bŭr-ô, Ky., city and county-seat of Daviess County, on the Ohio River, and on the Illinois Central, the Louisville and Nashville and the Louisville, Henderson and Saint Louis railroads, about 41 miles southeast of Evansville, Ind. It has steamer connections with all the principal river ports. It is in a farming and stock-raising region, and near are forests, coal and oil fields. In the vicinity are deposits of iron, lead, zinc and fire clay, and stone quarries are nearby. The chief manufactures are tobacco products, alcohol, wagons, carriages, electrical supplies, brick and tile and iron products. It has an extensive trade in tobacco products, coal, farm products, livestock and manufactures. The prominent public buildings are a government building, county courthouse, jail and the high school. Its educational institutions are Saint Francis Academy, public and parish schools. The mayor holds office four years. The waterworks and electric-light plant are owned and operated by the city. Pop. (1920) 17,424.

OWL CREEK MOUNTAINS, a small range of ridges of limestone, granite and schist forming a western extension of Bighorn Mountains in central Wyoming. They contain gold, copper, gypsum and phosphate. Consult report by N. H. Darton (published by 59th Congress, 1st Session, Doc. No. 219, 1906).

OWL PARROT. See KAKAPO.

OWLET MOTHS, a section of the family *Noctuidæ*, containing small species. The *Noctuidæ*

is an immense assemblage of night-flying moths made up of hundreds of genera and thousands of species, and represented in all parts of the world. They are as a rule of less than medium size and of dusky tints, and are closely allied to the tiger-moths (*Arctidæ*), from which they may be distinguished by the subcostal nervure of the hind wing anastomosing with the radial only near the base of the cell. In the fore wing the fourth and fifth radial nervures fork from the third which is connected by a cross-nervure with the second. The frenulum is present and the first maxillæ are well developed. The caterpillars are not hairy as a rule, and 10 prolegs are usually present. The pupa is sometimes naked and subterranean, lying within a rude cell of clay; sometimes enclosed in a cocoon made partly of leaves, etc., on the surface of the ground.

OWLS, nocturnal birds of prey of the group *Striges*. The owls form a compact, clearly circumscribed group solidified by many common characters, but the question of their relationship to other birds is one which ornithologists have found most puzzling. Formerly they were united with the other birds-of-prey, but the raptorial bill and claws, in which the resemblance to the hawks is most striking, may well be only adaptations to similar predaceous habits. On the other hand it is equally probable that the soft plumage, highly developed sense-organs, etc., are adaptations to nocturnal activity. As a result of more fundamental anatomical studies systematists now agree in the close relationship of the owls to the night-jars and their kindred (*Caprimulgi*) as a suborder (*Striges*), in the order *Coraciiformes*. This suborder consists of a single family (*Strigidæ*), including all the owls of the world, and embracing two subfamilies and a great number of species. The very characteristic physiognomy of the owls results chiefly from the development about the eyes of areas of radiating feathers, or facial discs, supported by a ruff of peculiar stiff recurved feathers. Frequently the head is ornamented by paired tufts of longer, erectile feathers called horns or ears, though they have nothing whatever to do with the sense of hearing. The general plumage is very soft and fluffy, making noiseless flight possible and giving an exaggerated idea of bulk. The feathers have no aftershaft; and some species, like the snowy owl, have the feet and toes thickly feathered to the claws, giving them a peculiar booted appearance. The head is always remarkably large, and the bill strongly hooked and cered. A peculiarity of the large, strongly clawed feet is the versatility of the outer toe, which may be directed forward, outward or completely backward and paired with the hallux at will. In correlation with their keen perceptions the sense-organs are greatly developed. The great staring eyes look directly forward, and, owing to their form, can rotate but slightly in their sockets, a peculiarity which explains the owl's habit of following with the head any object at which its gaze is directed. The somewhat cylindrical or truncated conical form of the eye results from the great development of the bony sclerotic or focusing ring. Unlike most birds the upper, and not the lower lid is chiefly employed in closing the eye, which is further protected by a conspicuous nictitating

membrane. Although many differences in the degree of its development are presented, owls are almost the only birds that may be said to have an external ear approaching that of mammals. It is concealed beneath the feathers, but, when best developed, as in the short-eared owl, covers the entire side of the head, and is provided with a prominent marginal fold of skin or "operculum." In this case the openings are asymmetrical, one being directed upward, the other downward, and in the great gray owl and its immediate allies even the skull bones are asymmetrical. The barn owls are separated from all of the others as a subfamily *Striginae*. They have the furculum complete and ankylized with the sternum, and the latter with an entire posterior margin. The remaining owls (*Buboninae*) have the furculum free from the sternum and either very thin or incomplete in the middle, and the posterior border of the sternum notched. Not less than 50 genera and 250 species of owls, varying in size from a sparrow nearly to a small eagle, have been described, and many exhibit several color-phases. The group is absolutely cosmopolitan.

Owing to their nocturnal habits, their ways are less well known than those of most birds, but in general are much alike. With the notable exception of such species as the snowy owl and hawk-owl, they seek concealment during the day in dark retreats, but become active after nightfall. Their prey consists of snails, insects, mice, birds, rabbits or even larger animals, according to the size of the species, which they approach on noiseless wing and usually grasp with one foot, after which it is borne away to a perch and torn to pieces. A few species feed on fishes, and one even on crabs, but none on vegetable matter. Undigested portions, as bones, hair and hard parts of insects are ejected in pellets from the mouth. Their voices present some variety; some hoot, some whistle, but the cry of many resembles a shrill laugh. Owls breed very early, many of them in late winter, and deposit their nearly spherical, white or whitish, eggs in holes in trees or rocks, in nests deserted by other birds or rudely constructed by themselves on the ground or in trees. One species, the American burrowing owl, nests in communities in or among the burrows of prairie-dogs, but the association does not assume the happy relation sometimes described. The young are interesting objects, thickly covered with down, usually white.

The mystery surrounding their nocturnal habits and their often lugubrious cries have made owls suitable objects of superstition among all peoples and in all ages. Among the ancients the owl was regarded on the one hand as a portent of dire calamity and its appearance near a sick chamber an omen of death; on the other, it was the bird of wisdom, the symbol of the goddess Athene. How deeply fixed and widely spread is the belief in the owl as an evil omen is shown by the frequency of its occurrence in all literatures and folklores. The Hindus have an interesting myth of the crow (night) and the owl (moon) contending for supremacy. Among the American Indians the owl figures in many legends. One told in the Kootenay tribe is to the effect that the wicked owl was in the habit of carrying off crying children. Through trickery it was finally killed

and its body burned by the coyote, but its spirit rose from the ashes as a swarm of blood-sucking mosquitoes. See the names of various species as BARN OWL, etc.

For an account of the numerous species of owls of the United States consult Baird, Brewer and Ridgway, 'North American Land Birds' (1874); Newton, 'A Dictionary of Birds' (London 1896); Bendire, 'Life Histories of North American Birds,' Part I (Washington 1892), and works mentioned under BIRDS; and for ancient and mediæval superstitions Gubernatis, 'Zoological Mythology' (1872).

OWNERSHIP is the dominion of a thing real or personal, which one has the right to enjoy and to do with as he pleases, even to spoil or destroy it as far as law permits, except that he is prevented by some agreement or covenant restraining such right. An owner continues to have the same right although performing no acts of ownership, and although another may perform such acts without his knowledge or against his will; but an owner may lose his right in a thing if he permit it to remain in the possession of a third person for sufficient time to enable the latter to acquire a title thereto. Any thing or property may be the subject of a joint ownership by two or more persons having an equal right to it. Ownership as applied to one's title to property is the right by which a thing belongs to a particular person to the exclusion of all others. The foundation of ownership is possession, but it is not sufficient as against one who can show a better right. Ownership is divided into perfect and imperfect: it is perfect when it is perpetual and when the thing owned is unencumbered with any real right toward any other person than the owner; imperfect when it falls short of this.

OWOSSO, ô-wôs'ô, Mich., city in Shiawassee County, on the Shiawassee River and on the Grand Trunk, Michigan Central and Ann Arbor railroads, about 80 miles west by north of Detroit and 30 miles north by east of Lansing. It was settled in 1836 by A. L. and B. O. Williams and Elia Comstock and chartered as a city in 1859. It is in a farming region and has considerable manufacturing interest. The chief industrial establishments are furniture factories, which have about 650 employees; casket factory, 250 employees; screen door and window factory, 250; car shops, 150; sugar works, 200; miscellaneous, about 200; and malleable iron products, 400 men. The prominent public buildings are the churches and schools. It has a business college, a Carnegie library, an armory and convention hall. There are eight churches. The three banks have a combined capital of \$300,000. It has commission form of government with mayor and two commissioners. The waterworks are owned and operated by the municipality. Pop. 12,575.

OX, a bovine animal; that is, a ruminant of the sub-family *Bovinae*, which includes the typical species of the large family *Bovidae* (q.v.); more specifically, an adult castrated male of some domesticated breed. An uncastrated adult male is a "bull," a female a "cow," a young individual of either sex a "calf," a yearling female a "heifer," a young castrated male a "steer" and a bull castrated when mature a "stag." The herd collectively is spoken of as "oxen" or "cattle." Hence, by extension, all

the *Bovinae* are spoken of as cattle, wild or tame, a list of which follows. The group is characterized by its large size and bulky form and by various minor characteristics, of which the foremost is the roundness, smoothness, horizontal up-curving growth and comparative shortness of the horns. Like the other sections of the family, antelopes, sheep, goats, etc., oxen are easily recognized but rather difficult to define technically. The history of the group begins, so far as known, in the Lower Pliocene (Siwalik) formations of India. The oxen apparently originated in that part of the world and reached Europe and North America in the time represented by the Upper Pliocene rocks. In some of the earlier species the females seem to have been hornless; but the type quickly assumed its proper form and some of those fossil in the Siwalik beds are closely related to our modern domesticated cattle. Europe possessed in the Pleistocene, or period just preceding the Glacial Period, a widespread, gigantic long-horned species named *Bos primigenius* and another species (*B. brachycerus*) with much shorter horns. Both seem to have survived the Glacial Period in sufficient strength to reoccupy the continent after the recession of the ice; and they constituted the great forest oxen, which Cæsar found in his campaigns in Gaul and Germany and to which, not distinguishing them, he gave the general name *urus*. Some survived as late, at least, as the reign of Charlemagne, and from them were derived, no doubt, the modern domesticated races of the Western World, possibly with some small and later admixture of native Eastern species. These cattle were tall, strong and seem to have differed mainly in the comparative length and shape of the horns; and there seems no doubt that a remnant of *Bos primigenius*, nearly, or, as some believe, quite pure, exists in the white cattle preserved in the Chillingham estates in the north of England (see CHILLINGHAM WHITE CATTLE); it is also regarded as certain that the Holstein breed is a direct descendant of this species. The other (short-horned) species has long been extinct, but was apparently the progenitor of the great body of European domestic cattle, whence have been derived the herds of America, South Africa, Australia and, in fact, all the world except the Orient.

The domestication of cattle began in prehistoric times; and some Asiatic species now extinct may have supplied the stock represented as in the service of the civilized nations of ancient Persia, Asia Minor, Syria and Egypt by the early carvings and paintings which have come down to us, but they may have been derived from one or both of the species above mentioned. They were carried to Carthage and westward and to southern Europe when the civilizations of Greece and the Italian Peninsula arose and some were no doubt gradually taken by Roman settlers into western Europe as fast as it was subjugated, where they would be crossed with the larger, hardier short-horned local races of Gaul. Apparently the native cattle of the British Isles were of the long-horned (*B. primigenius*) stock only; but when what now is England was conquered and colonized by the Romans and later by the Saxons, Normans, etc., the better short-horned cattle which they brought with them were substituted first in

the south of England and gradually elsewhere, replacing the British long-horns everywhere except in the extreme north, where the red Highland cattle perhaps represent them to this day. The Friesian and Holstein breeds of the Netherlands and the semi-wild Spanish cattle are regarded also as nearly direct descendants of these aboriginal long-horned oxen and from the Spanish stock, transported to South and Central America in the 16th century, came the vast plains-ranging herds of the Argentine pampas, Mexico, Texas and neighboring States. It was not until comparatively recent times that care and improved methods of breeding began to develop in England, northern France and the Netherlands the improved breeds now so distinct and valuable for beef or for milking. Most of the early cattle brought to eastern North America seem to have been of the short-horned English variety; and these, keeping pace with European development by intelligent selection and the frequent importation of foreign sires of high quality and mingled with the western "scrub" cattle, have produced the excellent varieties now to be seen in the United States and Canada.

Nearest to our domestic cattle are two East Indian species, the gaur and the gayal (qq.v.), which are domesticated to some extent by the people west of the Bay of Bengal. Closely related is the banteng (q.v.) of Sumatra. The common humped or Brahman cattle (see ZEBU) of India and eastward represent a distinct species, of which no wild herds remain and which has been bred into many distinct varieties, of which one of the most aberrant is the Abyssinian sanga. The yak (q.v.) of Tibet and the diminutive forest-ox (see ANOA) of Celebes, bring the list of oxen down to the buffalos. Of these (see BUFFALO) the East Indian species still exists in wild bands in the jungles of India and the Malayan Peninsula, but has been domesticated for a very long period and is used as a beast of draft and of burden throughout southeastern Asia and in many parts of tropical Africa. Africa has two native species, neither in domestication. A fourth species inhabits Mindanao, one of the Philippine Islands. The bisons (q.v.), composed of the American bison and the aurochs, neither of which have been domesticated to any practical extent, both of which are extinct except in small protected herds, complete the list of the bovine animals of the world.

Consult standard zoologies, especially the writings of Blanford upon the mammals of India, Persia and Abyssinia; Lydekker, 'Oxen, Sheep and Goats of the World' (1898); and the authors cited under BISON, BUFFALO, etc.

ERNEST INGERSOLL.

OX-BIRD, or OX-EYE. See DUNLIN.

OX-BOT, a bot-fly (q.v.) attacking meat cattle; a warble-fly. The well-known ox-bot or breeze-fly of Europe is *Hypoderma bovis*, and until about 1890 it was believed by naturalists that the very similar flies prevalent in North America were the same, but it is now known that they belong to a second species (*H. lineata*) locally known in the southwestern United States as heel-fly. The larvæ or warbles are called "grubs" by American stock-raisers, and affected cattle are said to be "grubby." These and various allied species parasitic upon domestic and

wild animals, and even upon humanity in certain tropical regions, constitute the family *Estridæ*. In the case of the American ox-bot (*H. lineata*) the flies appear early in spring and haunt feeding cattle, hovering especially about their legs, where they deposit their eggs mainly upon the hairs overhanging the hoofs. The egg is barely visible to the unaided eye, is cigar-shaped and has one end formed into a clasping appendage by which it is attached to the hair. Five or six are placed in a close row on each hair. The cattle lick themselves and gather these eggs upon the tongue, where they hatch, and the maggots make their way into the gullet, where they catch on the walls, force their way through by means of the sharp spines about the head, and nest in the wall-tissues of the throat until they have undergone a molt. They remain here many weeks, then make their way to the skin of the neck and work along beneath it to the back, where during winter the presence is shown by the swelling of the hide over them. There is evidence that some of the larvæ, at any rate, bore their way into the skin instead of entering by the gullet. These grubs are nourished by the pus and serum produced about them by their movements. Some weeks later, or toward spring, the maggots reach maturity, molt again, become nearly an inch long and at last force their way out through the skin; they then drop to the ground, the larval skin dries and stiffens and the maggot within separates itself from this old integument and turns into a pupa stage, which is speedily completed, allowing the fly to emerge in time to produce a brood before the end of the summer. The knowledge of this life-history was gained only as recently as 1890, mainly through the investigations of Dr. Cooper-Curtice; and it is not yet known whether the eggs and young of *H. bovis* pass through a similar series of events.

The damage done by ox-bots is very great, and is due to the perforation of hides by the escape of the maggots; loss of milk and beef due to the fretting and often stampeding of the cattle when the flies are laying their eggs; and general depreciation of the stock. The insect is so uncommon that it may be disregarded east of the Alleghanies; but it is exceedingly numerous and troublesome in the Mississippi Valley and Southwestern States, and the cattle there, especially in Texas, betray the greatest terror in the fly season, rushing headlong when a fly appears, and if possible dashing into the water and staying there. In addition to the harm to beef and milk caused by the nervousness, exhaustion and interference thus produced, one-half of the hides that reach market from the infested regions show perforation by warbles, and suffer a discount in price which on the average will amount to a third of the value of perfect hides. Consult Bauer, 'Monographie der Cestridenten' (1863); Ealand, E. A., 'Insects and Man' (London 1915); Howard, 'The Insect Book' (1901); Osborn, 'Insects Affecting Domestic Animals' (United States Department of Agriculture, 1896).

OX-BOW LAKES. See MEANDERS.

OX-EYE, a popular name for several composite plants. In America the name is most widely applied to *Helopsis*, three species of which are distributed from Nova Scotia to

Florida and westward to Arizona. They are perennials which bear abundant yellow flowers in the fall, but are not so popular in gardens as members of the genus *Helianthus*, the sunflowers. The ox-eyes of Europe are a species of *Buphthalmum*, which are sometimes grown in America in hardy borders. They have large flower-heads with long yellow rays, and resemble sunflowers. Being showy and of simplest culture they are worthy a place in gardens. In the New England States the name is given to the black-eyed susan (*Rudbeckia hirta*), and to the ox-eye daisy (*Chrysanthemum leucanthemum*). See DAISY.

OX-GALL, the bile of the ox, a greenish bitter fluid secreted by the liver of the animal. After being clarified it is suitable for various uses in manufactures and the arts, especially in the mixing of colors for water-color painting, its effect being both to increase their fluidity and to fix them. Another employment is as a cleansing agent in scouring wool, etc. It is also used in medicine, either in concentrated mass or powdered after being dissolved in alcohol and rendered clear, as a stimulant to the flow of bile and as compensation for the lack of the secretion of bile. It is further useful in the form of enemas.

OX-PECKER. See BUFFALO-BIRD.

OX-WARBLE. See OX-BOT.

OXALIC ACID, a dibasic organic acid which takes its name from the occurrence of its acid potassium salt in common sorrel (*Oxalis acetosella*). The same salt is found in other plants, notably the garden rhubarb, and the free acid is found in the leaves of the sugar beet. Calcium oxalate is common in many varieties of lichens. Oxalic acid is commercially prepared by heating sawdust, preferably that of the soft woods, with caustic soda and caustic potash by hot air with the addition of steam. The temperature required is about 570° F. At a lower temperature a large proportion of acetic acid is formed. The immediate product is oxalate of soda, which may be obtained in granular form by digesting the mass with boiling water and evaporating the filtrate. To prepare the acid in the free state, the sodium oxalate is boiled with milk of lime, and the calcium salt so obtained is decomposed with sulphuric acid. The product thus obtained contains some oxalates, and to get rid of these the crude acid is dissolved in a 10 to 15 per cent dilution of hydrochloric acid, and crystallized. It is then melted and recrystallized to remove the hydrochloric acid. Anhydrous oxalic acid may be obtained in the form of octahedral crystals, by allowing a solution of oxalic acid in sulphuric acid to stand for some days. The anhydrous acid has the formula COOH.COOH , or $\text{H}_2\text{C}_2\text{O}_4$, sublimes at 355° F., forming white needle-like crystals, which gradually absorb water from the air, falling into powder. The oxalic acid of commerce contains two molecules of water, crystallizes in the monoclinic system and is readily soluble in water and in alcohol. The hydrated crystals give off their water of crystallization when heated to 212° F. or when allowed to stand for some weeks over concentrated sulphuric acid. Heated to about 300° F., oxalic acid decomposes with the formation of carbon monoxide, carbon

dioxide, water and formic acid; a small quantity of oxalic acid also subliming at the same time, without change. When heated with concentrated sulphuric acid, it breaks up into water, carbon monoxide and carbon dioxide, the latter two gases being given off in equal volumes. Solutions of oxalic acid are decomposed in the presence of a bright light, yielding water and carbonic acid. This action may be measurably prevented or retarded by the addition of varying proportions of thymol. Oxalic acid forms two series of definite, crystallizable salts, according as one or both of its typical hydrogen atoms are replaced. The neutral oxalate of ammonia is used, in the laboratory, as a reagent for the detection of lime, since it gives, with a salt of calcium, an insoluble, white precipitate of calcium oxalate. Neutral oxalate of potassium reacts with ferrous sulphate to form a double oxalate of iron and potassium, which possesses powerful reducing properties, and is used as a photographic developer in wet plate processes. The acid oxalate of potassium (also known as salts of lemon, or salts of sorrel) is used for different purposes in the arts. Owing to its powerful oxidizing properties oxalic acid itself is used in calico-printing and in indigo dyeing as a "discharge." It is a constituent of several important dyestuffs. It is used also in various bleaching processes, especially the bleaching of straw and flax, and in the whitening of leather. In domestic economy it is employed for cleaning and polishing articles of brass and copper, for cleaning woodwork, removing ink stains, etc. For these purposes the oxalate and quadroxalate of potassium are equally efficient.

Poisoning by Oxalic Acid.—There is reason to believe that poisoning sometimes results from the frequent use of some cheap effervescent drinks in which citric acid is adulterated with oxalic acid. The hydrated crystals bear a close resemblance to Epsom salts, and being sometimes mistaken for them lead to fatal poisoning. Carelessness in domestic use also may result in poisoning. Oxalic acid is ranked as a corrosive poison, though, if taken in dilute solution, there may be no evidence of corrosion. The symptoms of this poisoning are heat and severe pain in the mouth, throat and stomach, difficulty in swallowing, a sense of constriction, vomiting—perhaps of blood—muscular cramps, sometimes convulsions, and purging, in some cases attended with blood. The lips, mouth and throat are at first red and swollen, then white. If the poisoning is severe the pulse is small and thready, there is a cold, clammy perspiration, then collapse, and, it may be, death. For treatment, first neutralize the poison by giving milk of lime, with a large excess of slaked lime, chalk, whiting or even whitewash from the wall, if no other form of lime can be obtained; then give a purgative dose of castor-oil, allay pain, and give stimulants if signs of collapse be present. Emetics are rarely needed and any liquid other than milk of lime should be sparingly used, if at all.

OXALIC ACID FERMENTATION.

Free oxalic acid is produced as the result of fermentation by the action of the mould *Aspergillus niger* upon a nutrient solution containing glucose, at a temperature of 60° to 70° F. The

acidity increases progressively in the solution to a certain maximum, then gradually diminishes and eventually disappears. By the addition of calcium carbonate to the solution the oxalic acid may be fixed in the form of the insoluble calcium oxalate. About half of the glucose present is thus converted into oxalic acid, the remainder being consumed in the growth of the mould.

OXALIS, a genus of herbs and shrubs of the family *Oxalidaceæ*. The species, of which there are about 200, are mostly natives of the warm parts of South America and Africa, but some are well-known weeds, called wood-sorrel, in the north temperate zone; many have tuberous or bulbous roots. The genus is generally characterized by digitate or ternate compound, clover-like leaves which "sleep" at night or in very cloudy weather, that is, the leaflets assume a resting position at such times. The flowers generally close under similar conditions. The seeds, which are contained in a capsular fruit, are thrown to considerable distances when the fruit bursts open. The best-known American species is the common wood-sorrel (*O. acetosella*). It is also a native of Europe and western Asia. Naturally it grows best in shady places and is often found covering the ground as thickly as grass, its little white, rosy-veined flowers appearing in abundance throughout the season. Probably the next best known is the violet wood-sorrel (*O. violacea*), a native of the eastern United States. It inhabits similar localities but has pinkish violet flowers. The tuberous roots of some species are used for food in western South America.

OXALURIA, a morbid condition of the system, in which a prominent symptom is the presence of crystallized oxalate of lime in the urine. See URINE.

OXENBRIDGE, John, English colonial divine in America: b. Daventry, Northamptonshire, 30 Jan. 1608; d. Boston, Mass., 28 Dec. 1674. He was educated at Cambridge and Oxford, preached for a time in England and later in the Bermudas, whither he made two voyages, held a curacy at Beverley, was pastor of a church at Berwick-on-Tweed, held a fellowship at Eton from 1652 until ejected at the Restoration (1660), and as a preacher was driven from the exercise of his office by the Act of Uniformity. In 1669 he came to New England, and on 4 May 1670 was ordained pastor of the first church at Boston. In 1672 he was appointed a licenser of the press. Among his works are 'A Double Watchword' (1661); 'A Seasonable Proposition' (1670); 'A Sermon at the Anniversary Election of Governor' (1672).

OXENDEN, Ashton, British clergyman: b. Broome Park, 1808; d. 1892. He was educated at University College, London; was holder of the living of Pluckley, Kent, in 1849–69, becoming honorary canon of Canterbury in 1864. In 1869 Oxenden was made bishop of Montreal and primate and metropolitan of Canada. Ill health compelled his resignation in 1878, after which he ventured to England and was later vicar of Saint Stephen's, Canterbury. He published 'The Cottage Library' (6 vols., 1846–51); 'The Pathway of Safety' (1856); 'The Home Beyond' (1861); 'The Parables of Our Lord Explained' (1864); 'A

Plain History of the Christian Church' (1864); 'My First Year in Canada' (1871); 'A Simple Exposition of the Psalms' (1872); 'The Christian Life' (1877); 'Counsel to the Confirmed' (1878); 'Touchstones' (1884); 'Short Comments on the Gospel' (1885). Consult his autobiography (London 1891).

OXENFORD, öks'ën-fôrd, **John**, English dramatist and critic: b. Camberwell, London, 12 Aug. 1812; d. London, 21 Feb. 1877. He was educated for the law and admitted to the bar in 1833, but chose a literary career. He translated from the German several notable works, among them 'Conversations of Goethe.' For 30 years preceding his death he was dramatic critic on the London *Times*. Among his plays are 'My Fellow Clerk' (1835); 'The Two Orphans'; 'Twice Killed' (1835); 'A Day Well Spent.'

OXENHAM, öks'ën-äm, **John**, English novelist. He was educated at Victoria University, Manchester, and was for some time resident in this country. Returning to England he gave up commercial pursuits and turned to literature. He has published 'God's Prisoner' (1898); 'Rising Fortunes' (1899); 'A Princess of Vascovy' (1900); 'Our Lady of Deliverance' (1901); 'A Modern Masquer' (1901); 'John of Gerisau' (1902); 'Under the Iron Flail' (1902); 'Bondman Free'; 'Mr. Joseph Scorer'; 'Barbe of Grand Bayou' (1903); 'A Weaver of Webs'; 'Hearts in Exile' (1904); 'The Gate of the Desert'; 'White Fire' (1905); 'Giant Circumstance' (1906); 'The Long Road' (1907); 'Pearl of Pearl Island' (1908); 'Great-Heart Gillian' (1909); 'Lawristons' (1910); 'Their High Adventure' (1911); 'Mary All-Alone' (1913); 'Bees in Amber' (verse); 'Broken Shackles' (1914); 'Everywoman and War' (1915). His war-time hymns and verse, such as 'For the Men at the Front,' 'All's Well,' 'The King's Highway' and 'The Vision Splendid,' struck deeply sympathetic chords and have attained great circulations.

OXENSTIERNA, öks'ën-shär-nä, **Axel**, **COUNT**, Swedish statesman: b. Fanö, 16 June 1583; d. Stockholm, 26 Aug. 1654. He studied theology and later law at Rostock, Wittenberg and Jena; at 20 entered the diplomatic service of Charles IX; was his Minister to Mecklenburg in 1606; entered the Senate in 1609; was head of the regency during the last days of Charles IX and through the minority of Gustavus Adolphus; became Chancellor of the Realm in 1612; acted as regent during the prolonged absence of the king; effected the Peace of Stolbova with Russia (1617); in 1626 was made governor-general of Prussia and in 1629 concluded the Peace of Altmart with Poland. After the death of Gustavus Adolphus at Lützen in 1632, Oxenstierna received almost unlimited powers, directed the Protestant league against Austria and held it together for four years. He returned to Sweden in 1636 and became the leading spirit in the regency of Christina, using all efforts to bring about peace with Germany. The Peace of Brömsebro, concluded in 1645 as the result of negotiations undertaken by his son John, the Swedish plenipotentiary to Germany, was highly displeasing to the queen. His obstinate opposition to Christina's plan of naming her own successor widened the breach between them, and he gradually withdrew from public affairs. He was,

next to Cardinal Richelieu, the ablest diplomatist of his age. He founded a Swedish colony on the Delaware river in 1638.

OXENSTIERNA, **Johan Gabriel**, **COUNT**, Swedish statesman: b. 1750; d. 1818. One of his masters was the critic, Olof Bergklint, after which Johan spent a year in the employ of the chancery and then was made secretary of legation at Vienna in 1770. After four years there he returned to become king's chamberlain, after which he held several high offices at court, and from 1792 to 1801 was marshal of the realm. In 1786 he became one of the first members of the Swedish Academy. He translated Milton and a part of Tasso into Swedish, but his literary fame rests in his poetic works, 'Skördarna' and 'Dagens Stunder.' His works appeared at Stockholm (5 vols., 1805-26). Consult Lamm, M., 'J. G. Oxenstierna, en gustaviansk natursvärmars lif och dikt' (Stockholm 1911).

OXFORD, öks'fôrd, England, a celebrated university city and county borough, the capital of Oxfordshire, 54 miles northwest of London (63½ miles by rail), is situated on a low-lying bank at the confluence of the rivers Thames (locally called Isis) and Cherwell. The rivers are crossed by several bridges, the principal of which are Magdalen Bridge, over the Cherwell, and Folly Bridge, over the Isis. In early times the city was surrounded by a wall, a portion of which still exists, intact, in New College Gardens. The castle of Oxford, famous for the Empress Matilda's escape over the frozen Thames in 1141, has disappeared, but the keep, built in the time of Rufus, remains entire, and is included in the precincts of the prison. The principal street, colloquially "The High," has a length of about 1,000 yards, and its greatest width is 85 feet. It is adorned by several of the noblest structures of the city, including Brasenose, All Souls University, Queen's and Magdalen Colleges, Saint Mary's (the university church), the New Examination Schools, together with quaint old houses. The botanic gardens, dating from the 17th century, add to the beauty of the street.

Educational Institutions.—The most interesting buildings are the colleges, component parts of the University of Oxford (see OXFORD, UNIVERSITY OF), but separate corporations, possessing property apart from the university. The buildings of the university proper are situated mainly between Broad and High streets. The most remarkable is the Bodleian Library, founded by Humphrey, Duke of Gloucester, built between 1444 and 1480, and restored by Sir Thomas Bodley about 1610. South of the Bodleian is the beautiful Radcliffe Camera (or Camera Bodleiana), erected 1737-49 to contain the books presented by Dr. Radcliffe to the university, but now used as a reading-room for the Bodleian. A new building for the Radcliffe Library has been erected in the precincts of the museum by the munificence of the Drapers' Company of London. North of the Bodleian stands the Clarendon Buildings, built from the proceeds of Clarendon's 'History of the Great Rebellion.' It was until 1830 the home of the Clarendon Press, but is now utilized for the various university offices. Westward of the library is the Sheldonian Theatre, designed by Wren, and presented by Archbishop Sheldon, a

large semi-circular chamber, capable of seating 4,000 persons, and used by the university for the conferment of degrees and other public functions. The university also possesses the New Examination Schools, the Taylor Institution, with the University Galleries and Ashmolean Museum; the Science Museum, the large university parks with the beautiful walk known as Mesopotamia, the Indian Institute and the Botanic Gardens. New laboratories and a new building for the Radcliffe Library have been erected in close proximity to the Science Museum. The New Schools are used for university lectures as well as for examination purposes.

The most remarkable of the various college buildings is Christ Church. The great quadrangle (Tom Quad), is the largest in Oxford; the gateway was begun by Cardinal Wolsey, completed from designs by Wren, and contains the famous bell known as "Great Tom." Christ Church is also remarkable for its magnificent dining-hall and staircase and its library. The cathedral, situated in the college precincts, fulfills also the function of a college chapel. Not less interesting is Merton College, with its ancient chapel and the "Mob Quad," the earliest quadrangle in Oxford. New College, a perpendicular building of the late 14th century, is due to the munificence and to the architectural skill of the great prelate, William of Wykeham. Its chapel, cloister and gardens are among the sights of Oxford, and its large quadrangle remains, except for the addition of a third story, much as it appeared to the founder's eye. Magdalen College is famous for its exquisite tower, its chapel and cloisters and the water walks, known as Addison's Walk. The buildings of All Souls College are also rich in architectural association, and every college has some feature of peculiar interest. The chapel and garden buildings of Saint John's, the library of Corpus Christi, Dr. Johnson's rooms at Pembroke and the general effect of the quadrangles of Corpus Oriel, Wadham, Balliol and University are illustrations of this. Modern additions to the architecture of Oxford have not been uniformly fortunate, but the latest additions to Brasenose and New College and the Examination Schools are worthy of the traditions of the university. Several of the colleges, notably Worcester, Saint John's, Wadham, Merton, New College and Trinity, have also beautiful gardens, and Christ Church possesses the famous Broad Walk in the Meadow. There are several colleges for women, the most important of which are Somerville College, Lady Margaret Hall, Saint Hilda's Hall and Saint Hugh's Hall. Mansfield College (perhaps the most successful piece of recent building in Oxford), intended for the education of men for the Non-Conformist ministry, was established in 1889; and buildings were opened in 1893 for Manchester College, removed from London in 1889.

Libraries.—The Public Libraries Act was adopted in 1852 and a library opened two years later. The present building, forming part of the new town-hall, was opened in 1895, and contains lending and reference departments, general ladies' newspaper rooms, and a children's reading-room and library. The library contains over 25,000 volumes. Special features are a large collection of local books and a

Braille library for blind students of the university.

Public Buildings and Charitable Institutions.—Notable buildings not connected with the university are the new municipal buildings containing the town-hall, public library, police station and court, and the various city offices, the Corn Exchange, numerous schools, the Radcliffe Infirmary, the Warneford Lunatic Asylum on Headington Hill, the Martyrs' Memorial, the Pusey Memorial House, with its Chapel of the Resurrection, and the New Theatre.

Churches.—Oxford is the see of a bishop. Christ Church, the cathedral church of the diocese, originally belonged to the priory of Saint Frideswide. Besides being the cathedral church of the diocese it is also the college chapel, but is of greater antiquity than the college, having been built in the 12th century. Saint Mary-the-Virgin, the university church, finely situated nearly in the centre of the High street, is conspicuous by its richly decorated tower, terminating in a beautiful spire 189 feet high. It ranks as one of the finest Gothic structures in Oxford. The church of Saint Martin's or Carfax was removed in 1896 to afford more room at the crossing of the four great thoroughfares, High street, Queen street, Cornmarket and Saint Aldate's. The ancient tower has been preserved. All Saint's Church is a Queen Anne building in the classic style, of which it is an excellent example. Saint Mary Magdalene presents several beautiful features, and has acquired much additional interest from the Martyrs' Aisle, added as a fit accompaniment to the Martyrs' Memorial, which stands close to it, near the spot where Ridley, Latimer and Cranmer suffered martyrdom. The most important of the other ecclesiastical edifices in Oxford are the churches of Saint Aldate, Saint Giles, Saint Peter in the East, Saint Thomas, Saint Barnabas, and the Roman Catholic church of Saint Aloysius. Saint Peter in the East is very ancient, and possesses Saxon as well as Norman work; it has a large crypt. Several handsome churches have been recently erected, Saint Philip and Saint James' and Saint Margaret's in the north; Saint Matthew's in the south and Saint Mary and Saint John's in the east, the last served by the Cowley Fathers, an active Anglican brotherhood. The city contains also places of worship for Methodists, Congregationalists, Baptists, Brethren and other non-conformist bodies. During the 19th century the city has been encircled by extensive residential suburbs. Less than two miles from Oxford stands, close to the river, the Norman church of Ifley, one of the most perfect pieces of Norman architecture in England.

Public Works, Government, etc.—The prosperity of the city depends mostly on the university, but a considerable trade is carried on in grain, and a cattle market is held twice a month. The city is governed by a council, consisting of a Mayor, 15 Aldermen and 45 councillors, of whom three aldermen and councillors are elected by the university. It returns one member to Parliament. Since 1892 the city has been lighted by electricity, it has a modern drainage system, an excellent water supply and municipally-owned tramways. Pop. about 53,043.

J. LOCKHART DOUGAN,

Chief Librarian, Public Library, Oxford.

OXFORD, Mass., town in Worcester County, situated on the New York, New Haven and Hartford Railroad, 10 miles south of Worcester. It contains an old Universalist church, a public library, woolen mills, shoe factories, etc. There are also many historic landmarks of the Huguenots, a colony of whom settled here. Pop. 3,820.

OXFORD, Miss., city and county-seat of Lafayette County, on the Illinois Central Railroad, 75 miles southeast of Memphis, Tenn. It is a cotton growing region and has a cotton gin and mill. It has two public schools, one for the colored race; it is the seat of the State University and in connection with its public schools affords a splendid educational centre. It was built in 1836, but was burned during the Civil War. Oxford is surrounded by farm lands well adapted to the raising of clover, corn, cotton, berries, fruits and vegetables. Pop. 2,150.

OXFORD, N. C., town, county-seat of Granville County, on a northern branch of the Tar River, and on the Southern Railroad, 42 miles north of Raleigh. It is in a fertile tobacco and cotton-growing region, has a large trade in tobacco and contains several tobacco warehouses and manufactories, also a saw-mill, furniture factory and an iron foundry. It has two orphan asylums, one for colored children, the other under the charge of the Masonic fraternity. It has no public high school, but is the seat of the Horner Military School (non-sectarian) and of the Oxford Female Seminary

(Baptist, 1850), with secondary and collegiate departments, and Granville Test Farm. Pop. (1920) 3,606.

OXFORD, Ohio, village in Butler County, on the Cincinnati, Hamilton and Dayton Railroad, about 35 miles north by west of Cincinnati. It is in an agricultural region and its chief industries are connected with farm products. It is noted as an educational centre; it is the seat of Miami University (q.v.), Oxford College (q.v.) and Western College. Pop. 2,200.

OXFORD CLAY, in geology, a term used by English geologists of the lower division of the Middle Oolitic (see OOLITE), making up with calcareous sandstones the Oxford (or Middle) Oolitic group, and so corresponding to one of the upper sections of the Jurassic. It is a blackish, brownish or dark blue clay, rich in fossil ammonites and belemnites.

OXFORD COLLEGE, a college for women established in 1849 at Oxford, Ohio. Besides the regular collegiate work, there are courses in music and art, and provision for post-graduate work; there is also a preparatory department. The collegiate work is arranged in three courses, classical, literary and scientific, leading to the degrees of A.B., B.L. and B.S. There are about 150 students and 17 instructors.

OXFORD MOVEMENT, a religious movement in the Church of England which originated among certain members of Oxford University. Its aim was the revival of religious life and doctrine in England on a purer and more primitive basis. The Church of England in the early part of the 19th century was in a condition in which reform was sorely needed. The fervid spirit of John Wesley and his successors had kept the spark of spiritual life still glowing in the heart of the masses, and the Roman Catholic Church as a consequence of Catholic Emancipation was rehabilitating itself. There were two main parties in the Church of England. There was the great Evangelical party who "whether they were admired as Evangelicals, or abused as Calvinists, or laughed at as saints, were inheritors not of Anglican traditions, but of those which had grown up among the zealous clergymen and laymen who had sympathized with the great Methodist revival and whose theology and life had been profoundly affected by it." This party numbered many men of power among its ranks who kept alive the spirit of such pious and earnest leaders as Hervey, Romaine, Cecil, Venn, Fletcher, Newton and Thomas Scott. They trusted less in ordinances, or in ecclesiastical rites and traditions, than in the stirrings of the individual soul toward God, private study of the Scriptures and constant prayer.

In contradistinction to these Low Churchmen were the old-fashioned High Churchmen who had existed in the Established Church since the time of Laud. They clung to the learning of such theology as had become the heritage of the Church through the teaching of a line of solid divines from Hooker to Waterland. Bishop Wilson of Sodor and Man in his 'Sacra Privata' was their model of practical and personal devotion, but they also drew for their religious life upon the stores of Andrewes, Jeremy Taylor and Ken. They preached calm, scholarly sermons, which embodied a gospel of

common sense; but did not appeal to the heart of the middle or lower classes. Besides these two great parties there was rising in the Church a spirit of free thought which should afterward develop into the Broad Church party of Stanley and Jowett. Connop Thirlwall and Julius Hare had become strongly tinged by the influence of recent German critical speculation, and Whately, Hawkins and Milman were looking for a wider field of religious life and conviction which should be bounded neither by the conventionalities of the Evangelicals, nor the somewhat frigid dignity and strictness of the High Church party.

The two chief leaders in the movement which was to bring a new life into the English Church were men of the very highest gifts—John Keble and John Henry Newman. There were two sides to the spirit of this movement; one was theological, the other moral. As illustrating these two aspects of religious life it is impossible not to cite the 'Christian Year,' which appeared in 1827 and embodied the essence of 'Tractarian' theology while it was warmed by the most pure and exalted ethical, if not ascetic, temper and tendency. When Newman began his ministry his sermons were remarkable for this same practical tone. His 'Holiness Necessary for Future Blessedness' was preached in 1826, before he was appointed vicar of Saint Mary's, and it struck the keynote of all his subsequent pulpit utterances. It was this intense moral earnestness that gave power and impetus to the new movement.

The political condition of England had much to do with the origin of the Oxford movement; Whig Erastianism was in the ascendant in Parliament; nor should the influence of the Romantic movement in literature with which the name of Walter Scott is associated be left out. When the definite movements began, the Reform Bill had just been passed, and it looked as if the government were about to invade the rights of the Church. It was at this time that a sermon of Keble's fired the train. "On 14th July 1833," we read in Cardinal Newman's 'Apologia,' "Mr. Keble preached the assize sermon in the university pulpit. It was published under the title of 'National Apostasy.' I have ever considered and kept the day as the start of the religious movement of 1833." The speaker described England as "a nation which had for centuries acknowledged as an essential part of its theory of government, that, as a Christian nation, she is also a part of Christ's Church, and bound, in all her legislation and policy, by the fundamental laws of that Church." He proceeds to charge the nation with now disavowing this principle, a course which implies "a direct disavowal of the sovereignty of God. If it be true anywhere that such enactments are forced upon the legislature by public opinion, is Apostasy too hard a word to describe the temper of such a nation?"

The effect of Keble's sermon was to cause a meeting at Hugh James Rose's parsonage at Hadleigh, Suffolk, between the 25th and 29th of the same July. Next in authority to Rose as leader in the movement (after Keble, Newman and Pusey) was William Palmer, and he has himself described the feelings with which the "Conspirators," as they were styled, met on that occasion. "We felt ourselves assailed by

enemies from without and foes within. Our prelates—insulted and threatened by ministers of state. . . . In Ireland—10 bishoprics suppressed. What was to come next? . . . We were overwhelmed with pamphlets on Church Reform. Lord Henley, brother-in-law of Sir Robert Peel, Dr. Burton, and others of name and influence led the way. Dr. Arnold of Rugby ventured to propose that all sects should be united by act of Parliament with the Church of England. Reports were prevalent that some of the prelates were favorable to alterations in the Liturgy. Pamphlets were in wide circulation recommending the abolition of the creeds (at least in public reading) . . . the removal of all mention of the Blessed Trinity; of the doctrine of baptismal regeneration; of the practice of absolution." The party pondered over what was the best means of opening the eyes of churchmen, and it was resolved at Hadleigh that this could only be done by writing, by publishing certain declarations, certain manifestos, and thus to carry out the spirit of Keble's sermon. In this way were born what Mozley afterward called "that portentous birth of Time" 'The Tracts for the Times.'

The first tract appeared 9 Sept. 1833. It was written by Newman. He wrote, as he says, under the conviction "that ancient religion had well nigh faded out of the land through the political changes of the last 150 years, and it must be restored." In the introduction he asserted the doctrine of Apostolic succession, and the ministerial power to give absolution. The early tracts produced a profound sensation. They awakened men's minds, and in many quarters the cry was raised that they contained "Romanism" in disguise; yet they quoted the Prayer Book, and the most authoritative English divines and even bishops were puzzled how to regard them. They were supplemented by the 'Churchman's Manual,' which explained the nature and claims of the Church and its ministers. In 1834 the party was joined by Edward Bouverie Pusey (q.v.), and he early contributed an elaborate tract on 'Fasting.' Between 1835 and 1840 the 'Tractarians,' as the promoters of the Oxford movement were called, had swollen to the dimensions of a large party. As a protest against its alleged Romanizing tendency a monument was erected in Oxford to the martyrs of the Reformation, Cranmer, Ridley and Latimer, but the "Memorial" had little effect in arresting the progress of the movement which was on its way to win the coming generation of English clergy to maintain the doctrines of Apostolic Succession, Baptismal Regeneration, Priestly Absolution, the Real Presence in the Eucharist, and the Divine Character of the Church. But in a short time the authorities both of Oxford University and of the Church of England became alarmed. Sumner, bishop of Chester, was the first to condemn the movement by denouncing in 1838 "the undermining of the Protestant Church by men who dwell within her walls

. . . who sit in the Reformers' seat and traduce the Reformation." The Tractarians undoubtedly made mistakes and showed impatience, exaggeration and little consideration for the scruples of those who did not accept their teachings. When the tract was published entitled 'On Reserve in Communicating Religious

Knowledge,' they ventured on dangerous ground, and touched on topics not relevant to their main crusade, laying themselves open to the charge of avowing the principle of keeping back part of the counsel of God. But the formation of a "Romanizing" section in the Tractarian party was not justifiably charged against them until the publication of Tract 90, in which Newman attempted to show that the 39 Articles of the Church of England could be so interpreted as to harmonize with the teaching of the Roman Catholic Church. This was the turning point in the history of the movement. The Tractarian doctrine was condemned by the Heads of Houses at Oxford. The bishop of Oxford forbade the publication of such views, and Newman yielded. The Tractarian candidate for the professorship of poetry, a man of undoubted genius, was defeated, and Mr. Ward, another Tractarian, dismissed from his mathematical lectureship at Balliol, and the climax was reached when Pusey was accused and found guilty of preaching doctrine contrary to that of the Church of England and was suspended from preaching within the university for two years. Finally a movement was set on foot to procure a vote of censure on Ward's 'The Ideal of a Christian Church,' in which the Roman Catholic Church was set forth as that ideal and the English Church condemned as not fulfilling it. The motion was passed by a majority of 58 members of the Convocation, and only failed of being ratified by the vice-chancellor through the interposition of a legal technicality. On 3 Oct. 1845 Newman requested the provost of Oriel to remove his name from the books of the college and university, and on the 8th completed his 'Essay on the Development of Christian Doctrine'; two days afterward he was received into the Roman Catholic Church. A host followed him.

The movement within the Church of England itself continued under the leadership of Pusey, who deplored Newman's secession to Rome and who even in its early days, to quote Newman, had been "able to give a name, a power and a personality to what was without him a sort of mob." The Gorham judgment (1850), in which the judicial committee of the privy council—which, being a civil court, the Tractarians claimed had no valid authority to act in ecclesiastical cases—decided that belief in Baptismal Regeneration was not necessary in order to hold a benefice in the Church of England, was followed by further secessions, among them, Manning. The Oxford revival, begun in the Church of England, profoundly affected all the Reformed churches, and while laying stress on ceremonial, on orderly and comely worship in the sanctuary and on the claims of the early Church and its creeds, laid no less emphasis on spirituality of life as an essential prerequisite for the priests and ministers of the Church. Consult in addition to the biographies and works of the outstanding figures of the movement whose names are mentioned in this article. Brown, E. G. An exhaustive bibliography by Canon S. L. Allard appears in Vol. XII of the 'Cambridge History of English Literature' (1915).

OXFORD UNIVERSITY, England, at Oxford (q.v.), its foundation by tradition, ascribed to Alfred the Great, who had a mint in the city, is believed to have its authentic origin in the quarrel between Henry II and Becket, when the king, about 1164, directed an ordinance against the partisans of Becket, to the effect that all clerks possessing revenues in England and resident in Paris had to return in three months "as they loved their revenues." Philip II of France was aiding Becket, and Henry forbade English clerks to study at Paris. Just after the edict the schools of Oxford became very flourishing and assumed the character of the contemporaneous university; the existence of doctors of various faculties as well as of masters and scholars being recorded about 1187 in connection with the celebrated visit of Giraldus Cambrensis. The earliest public document known to exist, which applies the title of university (*universitas*) to the schools of Oxford is one which dates from 1201. In 1214 the bishop of Lincoln, the ecclesiastical superior of the monks gathered within his diocese, appointed a chancellor for their government, and the constitution which arose out of such elements has been molded into its present form in part by the authority of the Crown and of Parliament, in part by the inherent self-governing power of the university itself. The first chancellor known to have been appointed was Robert Grossteste, about 1224, who was afterward bishop of Lincoln. Other authorities represent that its first charter was that granted to it by Elizabeth in 1570, when it was enacted that henceforth the university should be known by the name of "The Chancellor, Masters and Scholars of the University of Oxford," and by no other name, upon which its privileges depended until the passing of the Oxford University Act of 1854. The elective franchise was conferred upon the university in 1604, since which time it has returned two members to Parliament.

The collegiate system at Oxford dates from the 13th century. At first the students who congregated at the university had no special places of abode provided for them, but had to find accommodations for themselves. As the students found it cheaper to unite and rent a single house in which they might live together than to provide each for himself, they frequently did so, forming halls, hostels or inns. Sometimes, for the sake of giving greater facilities to study, sums of money would be given or bequeathed to the university for the erection of buildings in which the students might live without any more expense than was necessary for their maintenance. The first who went further than this was William of Durham, who, dying in 1249, bequeathed a sum of money to the university to provide a permanent endowment for the maintenance of a certain number of "masters." The first purchase was made in 1253, and with this purchase originated University College. There were

two other colleges founded during the same century—Balliol College, in 1263, and Merton College, founded at Maldon in Surrey in 1264, and removed to Oxford before 1274. This last college is said to have been the first in which the collegiate system in its modern form, or a form resembling the modern one, was instituted, the college being made a separate corporation, with a separate charter and separate statutes. The first statutes of University College as a separate corporation are dated 1280. At the beginning of the 14th century, while there were no more colleges than the three just mentioned, there were about 300 halls. As the number of colleges increased, and their growing endowments attracted greater numbers of students, the halls declined in numbers, especially since the attendance of students diminished in the centuries following the 14th. At the beginning of the 16th century the number of colleges had increased to 10, while that of the halls had declined to 55. There are now 21 colleges, all of which are separate corporations, and, with two exceptions, have endowments for fellows and scholars. At Christ Church the fellows are distinctively called "students" (ordinary students being, of course, called undergraduates). All Souls College has no scholars or undergraduates, except a small number of "Bible-clerks," and Keble College has no fellows. The fellows and scholars at Oxford hold pretty much the same position as at Cambridge (see CAMBRIDGE, UNIVERSITY OF, and FELLOWSHIP). Besides the colleges, there is one public hall, Saint Edmund Hall. It is not a separate corporation, and has no endowments for fellows, and it will be united to Queen's College on the occurrence of the next vacancy in the principalship, as Saint Mary's Hall has been incorporated with Oriel. The following are the names of the colleges in the order of their reputed foundation, each being separately noticed in the body of this work: University, Balliol, Merton; Exeter (founded 1314), Oriel (1326), Queen's (1340), New College (1379), Lincoln (1427), All Souls (1437), Magdalen (1458), Brasenose (1509), Corpus Christi (1516), Christ Church (1546), Trinity (1554), Saint John's (1555), Jesus (1571), Wadham (1612), Pembroke (1624), Worcester (1714), Hertford and Keble. The two last mentioned date from last century. Hertford is the restoration of an old foundation, while Keble (which is a "new foundation" and not a college in the strict sense) was founded in 1870 for the education solely of members of the Church of England; it enjoys the privileges (except as regards the academical status of its head) which are possessed by other colleges in the university. There are also three private halls, governed by "licensed masters"; and since 1884 one college and four halls for women have been established, Somerville College and Lady Margaret, Saint Hugh's and Saint Hilda's halls. Women cannot become members of the university or take degrees, but are admitted to the university examinations, and the names of those who pass or take honors are officially published. The largest of the colleges is Christ Church, established in 1546 by Henry VIII, from funds collected by Cardinal Wolsey; it is commonly known as "the House" ("Ædes Christi"). In the 15th century an enactment

was passed requiring all students who joined the university to become members of some college or hall, and this condition continued to be the law until 1868, when persons were permitted, under certain conditions, to enjoy the privileges of the university without so doing, keeping their statutable residence in approved houses or lodging in the town. Those who avail themselves of this permission are called "non-collegiate students." They are exempt from the heavy expenses inseparable from living in college rooms and pay small tutorial fees.

The constitution of the university is fixed by the act of 1854, which modifies that granted by the act of Elizabeth. The style or title by which the corporation is known is The Chancellor, Masters and Scholars of the University of Oxford. Legislation in university matters has to be prepared by the Hebdomadal Council, and pass through two bodies, the Congregation of the University and Convocation. There is also another body, the Ancient House of Congregation, made up of the *necessario regentes* and *regents ad placitum*, whose functions are confined to ratifying the nomination of examiners and to the granting of ordinary degrees. The House of Convocation consists of all who have been admitted to the degree of master of arts, provided their names have been constantly kept on the books of some college or hall, or of the delegates of non-collegiate students, and in the last resort Convocation has supreme control over the action of the university. Congregation consists of all masters and doctors resident in Oxford, and most matters are settled by it, appeals to the superior body of Convocation against a decision of Congregation being rare. The Hebdomadal Council consists of certain officials and certain members elected by Congregation. The official members are the chancellor, the vice-chancellor and the two proctors. The elected members are six heads of colleges or halls, six professors and six members of Convocation of not less than five years' standing. The members of Convocation elected may be either heads of houses or professors. The election takes place once in three years. The elected members hold office for six years, and half of them are chosen on every occasion. They meet every Monday in term time (whence the name of the body), and when convoked by the vice-chancellor. All legislative measures originate with them, but most of the ordinary business of the university is transacted by boards of delegates or curators elected or appointed *ad hoc*.

The principal officers of the university are the chancellor, the high steward, the vice-chancellor, the two proctors, the public orator, the keeper of the archives and the registrar. The dignities of chancellor and high steward are almost purely honorary, and are usually conferred on noblemen. The vice-chancellor, who is nominated by the chancellor from the heads of colleges, and chosen in the order of their election as heads, holds office for four years, and is now, in fact, the supreme executive and judicial authority of the university. The principal duty of the proctors is to maintain the discipline of the university, but they also serve *ex officio* on most of the university boards and delegacies.

There are over 100 professorships, lecture-

ships and readerships in the University of Oxford, besides the lectureships, etc., in the separate colleges. The university professors deliver lectures on the subjects for which they hold their professorships, but attendance on these lectures is compulsory on none of the students.

The colleges are corporate bodies distinct from the corporate body which forms the university. They are not subject to laws and regulations made by the university; they manage their own property, elect their own officers and even the proctors have no power within their walls. Some university professors are entitled to privileges and emoluments in colleges, and in many matters the colleges and the university recognize each other's regulations. But the true key to the intimate relations existing between the university and colleges is to be found in the fact that the great majority of the members of the university belong to the colleges and all members of the colleges are members of the university.

The old distinctions separating undergraduates into different classes (peers and their eldest sons, fellow and gentlemen commoners) have disappeared. "Scholars," that is students who by competitive examination have obtained a place on the foundation of a college—carrying with it a stipend of \$400—wear gowns differing from those of ordinary students or "commoners." Every student on entering his college is assigned to a tutor, who is responsible for the direction of his studies, and to whom he may apply for advice. The morning is devoted to attending lectures, or to private reading; the afternoon or the early part of it is universally surrendered to outdoor exercise; the evening after "hall" (the common name for dinner), is given by reading men to their studies, as well as to the social and literary meetings which form so much of the charm of college life. There is a university club, known as the Union Society, in whose hall there is held a weekly debate on some public topic. There are also a dramatic club and various musical societies which give performances regularly during term, besides many social clubs. The expenses of living at Oxford vary as the students; on the most economical system they cannot be brought below \$800 per annum. The total number of undergraduates on the book is about 3,600, but the number of those resident is usually 3,000. During the Great War the members were reduced almost to the vanishing point.

There are four terms in the university year at Oxford; Michaelmas term, which lasts from 10 October to 17 December; Hilary or Lent, from 14 January to the day before Palm Sunday; Easter term, from the Wednesday after Easter to the Friday before Whitsunday, and Trinity or Act term, from the day before Whitsunday to the Saturday after the first Tuesday of July; Michaelmas and Hilary terms are kept by six weeks' residence in each and Easter and Trinity terms either by three weeks' residence in each or by 40 days' residence in both jointly.

The degrees conferred by the university are those of bachelor and master in arts; bachelor and doctor in divinity, civil law, medicine, letters, science and music and bachelor and master in surgery. The most important function of the university, however, is the conferring of de-

grees in arts. Twelve terms of residence are required for the degree of B.A., which must be taken before any other degree (except those of B. Litt. or B. Sc. and bachelor or doctor of music) can be conferred. No further residence is necessary for any degree, and no residence whatever is required for degrees in music. Candidates for the degree of B.A. must pass three distinct examinations: Responsions (known among undergraduates as "Smalls") before the masters of the schools (six in number); first public examination (Moderations or "Mods") before the examiners known as moderators (in the pass school six, in the classical School seven, in the mathematical three); and the second public examination (or "Greats") before the public examiners (six in the Pass School, five in the school of *literæ humaniores*, and three, four or five in each of the other eight honor schools, namely, mathematics, natural science, jurisprudence, modern history, theology, Oriental studies, English literature and modern European languages). Candidates are admitted to pass Moderations at their second term, and to a Final Pass School as soon as they have passed Moderations. Honors may be obtained in each of the two public examinations. The first consists of an examination in Scripture, or an alternative Greek or Oriental book, and in either classics or mathematics for a pass or honors. Candidates are admitted to the honors examination only from the fifth to the eighth term from their matriculation, and are put to a much severer test than candidates for a mere pass. The successful candidates are arranged by the moderators according to merit in four classes, in each of which the names are published in alphabetical order—a feature of Oxford honor lists. In the second public examination honors are conferred in each of the nine honor schools already mentioned. Successful candidates are arranged by the public examiners in four classes according to merit, and their names published in these classes in alphabetical order. Candidates in the Pass School are examined in three subjects chosen from the following four groups: (1) Classics, classical history, Sanskrit and Persian; (2) Modern languages and history, political economy and a branch of legal study; (3) Mathematics and six branches of natural science; (4) Religious knowledge. Not more than two subjects may be chosen from any one group, but one of the subjects must either be classics (two books in Greek or one Latin and one Greek), Sanskrit, Persian or a modern language (either French or German, with composition and literary history). A B.A. may proceed to the degree of M.A. without further examination or exercise, in the 27th term from his matriculation, provided he has kept his name on the books of some college or hall, or upon the register of non-collegiate students, for 26 terms. In the case of all other degrees (except honorary ones) some examination or exercise is necessary.

Affiliated colleges are Saint David's College, Lampeter (1880); University College, Nottingham (1882); Firth College, Sheffield (1886); University College, Reading (1899); Hartley University College, Southampton (1903); Exeter Diocesan Training College (1906); Royal Albert Memorial University College, Exeter (1908), and a number of colonial universities.

Students accredited from these affiliated colleges are admitted to the Oxford public examinations after a reduced period of academical residence, they are not required to pass Responsions, and can take their B.A. degree after eight terms' residence, provided they have obtained honors at either the first or second public examinations.

The University of Oxford possessed the patronage of few church livings in its own right, but through an act of James I, Roman Catholics are disabled from presenting to any ecclesiastical benefice and their rights within 25 of the counties of England and Wales are made over to this university, those in the other 27 counties being conferred on that of Cambridge. Many of the colleges possess considerable ecclesiastical patronage. There are between 30 and 40 scholarships and exhibitions in the gift of the university, besides those belonging to the various colleges and halls. Of international importance are the Cecil Rhodes scholarships, dating from 1902, each of the annual value of \$1,500, to be held by students from every important British colony, from Germany and from every State and Territory of the United States of America. There are also several valuable prizes, such as the Stanhope, for a historical essay; the Newdigate, for an English poem; and the Gaisford, for composition in Greek prose and verse. The Radcliffe traveling fellowships are awarded to enable students of natural science to prosecute their studies abroad. Consult Clark, 'The College of Oxford' (1891); Corbin, 'An American at Oxford' (1903); Fulleylove and Thomas, 'Oxford' (1904); Gribble, 'The Romance of Oxford Colleges' (1911); Hutton, 'Literary Landmarks of Oxford' (1903); Lang, A., 'Oxford Notes' (1879); Lyte, 'History of the University of Oxford' (1886); Rashdall, 'Universities of Europe in the Middle Ages' (1895); Smith, Goldwin, 'Oxford and Her Colleges' (1895); the series of 'College Histories' and the 'University Calendar'; Wallace, 'Old Colleges of Oxford' (1912), and the 'Student's Handbook to the University and Colleges of Oxford.'

PHILIP MOLYNEUX,

Editor of the Oxford University 'Gazette.'

OXIDASE, any member of a certain group of enzymes, which are distinguished, as a class, by their power of inducing the direct oxidation of sugars and certain other substances. The chemistry of the oxidases is very imperfectly known, but the group appears to be widely distributed in the vegetable kingdom, and it probably plays an important rôle in the chemical changes that occur in the growing plant. Oxidising enzymes are also found in animals. Artificial oxidases have been prepared by Davy-Henault from faintly alkaline solutions of gum treated with solutions of manganese salts.

OXIDE, in chemistry, a compound formed by the direct union of oxygen with a metallic base or with an organic radical. The oxides may be classified, in a general way, as acid, basic and neutral. An acid oxide is one which has acidic properties or which combines with the elements of water to produce an acid. Sulphur trioxide, SO_3 , is a familiar example of this class of oxides, as it unites directly with water to produce sulphuric acid. Basic oxides are

those which have basic properties or which are capable of uniting with acids so as to produce salts. Calcium oxide (lime), CaO , is of this character. Neutral oxides are those which are neither acid nor basic in any marked degree. The magnetic oxide of iron, Fe_3O_4 , is an example of this class. The oxides are also classified in accordance with the proportion of oxygen and base that they contain. When two oxides of the same base are to be distinguished, that which contains the more oxygen in proportion to the base is sometimes called the peroxide, the other being called the suboxide. CuO , for example, may be called copper peroxide, and Cu_2O copper suboxide. These particular terms, however, are not used as generally as formerly and are usually applied to the highest and the lowest oxides in a series of more than two. The term protoxide is sometimes applied to a neutral oxide which contains a single oxygen atom in combination with one atom of a divalent base or with two atoms of a monovalent base. An oxide containing one, two, three, four or five atoms of oxygen is called the monoxide, dioxide, trioxide, tetroxide or pentoxide of the corresponding base. Occasional departures from this simple rule will be met with in modern chemical nomenclature, but in such cases the anomaly is due to some peculiarity in the behavior of the oxide or to the difficulty of changing a name after it has once been definitely adopted, even though it be erroneous when judged by correct principles. The gas whose formula is NO , for example, is commonly known as nitrogen dioxide, as though its formula were N_2O_2 . A sesquioxide is an oxide containing three atoms of oxygen to two of the base; the name being derived from a Latin word signifying "one and a half." Sesquioxide of iron, for example, has the formula Fe_2O_3 . See PEROXIDES.

OXLEY, òks'li, James Macdonald, Canadian author and lawyer: b. Halifax, Nova Scotia, 22 Oct. 1855; d. 1907. He was graduated from Dalhousie University, Halifax, in 1874, studied at Harvard in 1876-77 and was admitted to the bar in 1878. He practised law in Halifax in 1879-83, when appointed legal adviser in the Dominion Department of Marine and Fisheries. He resigned from this office in 1891 and engaged in the life insurance business in Ottawa and Montreal. Beside 'Nova Scotia Decisions' (1880-83), of which he was joint editor, he has written a long series of boys' books, such as 'Donald Grant's Development' (1892); 'Archie of Athabaska' (1893); 'In the Swing of the Sea' (1897); 'Fife and Drum at Louisburg' (1899), etc., and 'Lhasa at Last: a Journey to the Forbidden City of Tibet' (1900).

OXNARD, òks'närd, Cal., city in Ventura County, on the Southern Pacific and Ventura County railroads, 65 miles northwest of Los Angeles. It contains a public library, beet-sugar mills and refinery, machine shops, wood-working establishments, etc. The city owns the water-supply system. Pop. 4,417.

OXUS, òk'süs, or **AMU DARYA**, ä moo'-där'yä, a river of central Asia. It is formed by the confluence of the Pamir and Ab-i-Panja rivers in the Pamirs. The Pamir, which flows from Lake Victoria, 13,400 feet above sea-

level, and the Oxus after the confluence of the Ab-i-Panja and the Pamir, form the greater part of the boundary between Afghanistan and Russia. This part of the river is about 680 miles long; the course is first for about 150 miles in a direction, in general, westerly, then north for 120 miles, then west-northwest for about 50 miles, then southwest for 100 miles. Here it leaves the mountains which have previously come down almost to its banks and runs about 260 miles west through plains, which are particularly wide along its southern bank. From the confluence of the Kunduz near the beginning of this stretch to the mouth there are no affluents on the southern bank, for all streams to the south are swallowed up by the sands of the desert. The greatest width of the Oxus at flood is over 1,000 yards, its greatest current is five miles per hour. The stream is fordable at a few places in the plains. Elsewhere it is crossed on rafts made of inflated skins or on ferries worked by swimming horses. At Charjui the river is crossed by a railroad bridge on the Merv-Bokhara line. The river is navigable below Charjui, which is about 150 miles from the Afghan border, and there is a regular service by flat-bottomed paddle steamers as far as Pata Kissar. Consult Rawlinson, Sir H. C., 'The Road to Merv' ('Proceedings' of the Royal Geographical Society, new series, Vol. I, London 1879); Krapotkin, 'The Old Beds of the Amu-Darya' (*Geographical Journal*, Vol. XII, London 1898).

OXY-ACIDS, according to older chemical usage, are acids which contain oxygen; those containing hydrogen without oxygen being called hydracids. Nitric acid, HNO_3 , for example, was called an oxy-acid, while hydrochloric acid, HCl , was called a hydracid. The term oxy-acid is not often used in this sense at the present time, but organic acids which contain the radical hydroxyl, OH , are frequently called oxy-acid, or, more correctly, hydroxy-acids. The organic acids of the lactic acid series, for example, may be regarded as derived from those of the acetic acid series by the substitution of a molecule of hydroxyl for an atom of hydrogen and they are, therefore, oxy-acids or hydroxy-acids, according to the more modern terminology. Acetic acid, for instance, has the formula CH_3COOH , and glycollic acid (which belongs to the lactic acid series) has the formula $\text{CH}_2\text{OH.COOH}$. Glycollic acid may, therefore, be regarded as oxy-acetic acid or hydroxy-acetic acid, if considered as being derived by substituting OH for one of the hydrogen atoms of the methyl group in the acetic acid. Lactic acid itself may be regarded as hydroxy-propionic acid, the formula of propionic acid being $\text{C}_2\text{H}_5\text{COOH}$, while that of lactic acid is $\text{C}_2\text{H}_4\text{OH.COOH}$. Oxy-acids are thus alcohols at the same time as they are acids.

OXYACETIC ACID. See GLYCOLLIC ACID.

OXYGEN. See LIQUEFIED AND COMPRESSED GASES.

OXYHÆMOGLOBIN. See HEMOGLOBIN.

OXYHYDROGEN LIGHT. See CALCIUM LIGHT.

OXYRHYNCHUS, Egypt, an ancient town, now represented by Bahnasa on the Bahr Yusuf or Joseph Canal, about 100 miles south of Cairo.

The site presents mounds of ruins, covering an area unsurpassed by few ancient Egyptian towns. Opened and explored since 1897, these mounds have yielded rich finds in papyri containing many precious treasures of lost classical and early Christian literature. Greek papyri unearthed in 1897 and in 1903 include 3d century fragments of the "logia" or "Sayings of Jesus." (See AGRAPHIA). Among the Latin papyri is a fragment of the epitome of Livy's history covering books 37-39 and 49-55. On the back of this papyrus is written the largest piece of the New Testament on papyrus yet discovered, namely, the Epistle to the Hebrews. Another fragment comes from the Septuagint version of Genesis—a century older than extant vellum manuscripts of the same book. Among other Greek papyri is a 1st century B.C. copy of an epinician ode, by a poetess, perhaps Corinna, the rival and reputed teacher of Pindar; epigrams by Leonidas, Antipater and Amyntas; part of a philosophical dialogue in which the tyrant Pisistratus is one of the speakers; a long 2d century papyrus contained an invocation to a goddess, and on the back an account of a miraculous cure effected by Imhotep, the Asclepius of the Greeks and the Æsculapius of the Romans. Other finds comprise portions of the works of Homer, Herodotus, Thucydides, Sophocles and other classical authors, commercial and legal documents, private letters, etc., throwing interesting sidelights on social life in Egypt during the Greek and Roman dominations. In early Egyptian times called Pempte, the capital of a nome, here the Oxyrhynchus or "sharp-mouthed fish" was worshipped, while at Cynopolis (Dog Town), the neighboring city, the dog was revered, as recorded by Plutarch in the quarrels that arose between the two cities over the mutual revilings concerning the respective sacred animals. Oxyrhynchus had a flourishing Greek colony under the Ptolemaic dynasty. With the advent of the Christian era convents were established which attained a population of over 20,000 monks and nuns, to whom are due the wealth of ancient literature preserved and since discovered among the ruins. Consult Grenfell, B. P., and Hunt, A. S., 'The Oxyrhynchus Papyri' (London 1898-99), and 'New Sayings of Jesus and Fragment of a Lost Gospel from Oxyrhynchus' (London 1904).

OXYRHYNCHUS, the name given by the Greeks to a fish of the Nile (*Mormyrus oxyrhynchus*), formerly revered by the Egyptians, who refrained from eating it. It was sacred to the goddess Hathor and is frequently represented on sculptures and coins. The Egyptians embalmed and buried the oxyrhynchus with great pomp. It has a long snout and a pseudo-electric organ. Its modern name is "mizdeh." See MORMYRUS.

OXYSALT, or OXISALT, a salt of an oxy-acid. See OXY-ACIDS.

OXYURIS, a genus of small thread-worm parasite in man; the male of *O. vermicularis* is about one-sixth of an inch and the female about half an inch long, and inhabits the rectum of children and of old people in numbers, setting up inflammation. See NEMATODA; THREAD-WORM.

OYAMA, ô'yä'mä, Prince, Japanese field-marshal: b. Satsuma, 1842; d. 10 Dec. 1916. He was a cousin of the famous Saigō Takamori, who headed the Satsuma Rebellion of 1877-78. Oyama fought on the side of the Imperialist forces during the war of the restoration, and was one of the earliest students of foreign military methods, having been dispatched to Europe by the government at the time of the Franco-Prussian War, when he attached himself to the Prussian forces, remaining at his post until the conclusion of the siege of Paris. Shortly after his return the Satsuma Rebellion broke out and Oyama commanded a brigade of the Imperial forces dispatched against his cousin. Oyama did not hesitate to apply his Western skill and experience to the undoing of the rebels, and in September 1877 he returned in triumph to Tokio. He was soon afterward promoted to the rank of lieutenant-general and appointed chief of the general staff. In 1880 he was again given a portfolio as Minister of War. In 1894, when war with China broke out, he went to Manchuria in command of the second army, which captured Port Arthur and Wei-Hai-Wei. His record took the form of a succession of triumphs, and at the close of the struggle he was promoted to the rank of marquis. By 1898 Oyama had been advanced to the status of field-marshal. In the war with Russia, Oyama acted as commander-in-chief, and added to his reputation by a series of victories. A principedom was bestowed upon him for this achievement. The Princess Oyama was among the first of the girl students to be sent abroad by the empress in the early seventies, and spent many years in the United States.

OYER (oi'ër) **AND** **TERMINER**, tër'-mî-nër Court of. See COURT.

OYOMEI PHILOSOPHY. Wang Yang-ming (q.v.), pronounced Oyomay in Japanese, propounded a system of thought, which re-produced and expanded in Japan, from 1650 to 1850, fed the minds of almost every one of the men who created New Japan. In place of the original Chinese religion, when the forefathers worshipped a personal god, Confucianism substituted an abstract entity devoid of personality. After Confucius (q.v.) had set down in literary form the traditions and teachings of the ancients, in the canon of the Five Classics, these books became the basis of all Chinese culture and the point of departure for all philosophic discussion, during 25 centuries, the commentaries being countless and the derivative literature uniquely voluminous, among which the names of Mencius (q.v.) and Chu Hi (q.v.) are the chief. The former expounded the system of the sage, making it a political organon, with a strong flavor of democracy—so much indeed that when the Chinese heard of the government of the United States of America, they imagined that "the barbarians" had got their ideas from Mencius! After the long struggle with Taoism (q.v.) and Buddhism, Confucianism, in its mediæval statement by Chu Hi, issued, not merely as a canon or a ritual, but as a pantheistic-creed. According to this, the one abstract principle evolved out of itself the Great Absolute (Ri), primordial cause of all existence. In its motion, the male principle was produced; in its rest, the female. Thus heaven

and earth were made and through the supreme cause eternally continuing its activities, all things, animate and inanimate, came into being. This breath of nature (Ki), or the energy animating these two ever-acting principles, which never cease working, follow fixed, inscrutable and immutable laws. To be in harmony with these laws is man's chief end of being. The system of Chu Hi was eclectic, for he sought to show that in the various schools of thought much the same substance of truth was taught; and also conservative; and indeed these were largely accepted as the teaching of the past. Yet against this scientific philosophy and critical erudition based on realism was the idealistic intuitionism of his contemporary Lu (b. 1140 A.D.) whom the Japanese call Riku, who considered that the keeping of the heart aright was the beginning and aim of all study. He, however, wrote little, but Oyomei (Wang Yang-ming), his first great follower, was a man, skilful with pen and tongue, of infinite wit, rich in humor, apt in illustrations and possessed of a fine literary style. Instead of repeating past wisdom, he sought to find all truth within his own heart. The heart and Ri are one. If a man knows his own heart, he knows the way and heaven. To act is to know. If we do not act right, we do not know. (*Exitus acta probat*). All knowledge is useless that is not expressed in acting. The system of thought elaborated by Chu Hi, when introduced into Japan in the 17th century, won the adherence of educated men, displacing Buddhism, which was abandoned to the lower classes. As in China, it was adopted as the official orthodoxy by the government, for in it the Yedo usurpers saw a formidable ally and support for their despotism. Thinkers of different mind ran the risk of ban, persecution or death. Yet already, disciples of Oyomei had begun to expound and apply a doctrine possessing so peculiar a charm and one harmonizing so subtly with the Japanese temperament. To them, as led by Oyomei, the whole universe was incessantly surging on to higher spheres of development and calling upon men to join its glorious advance. Moreover, their good works were quickly manifest in philanthropy, the economic improvement of the landscape, the fertility of the fields and the morals of society. Nakae Tōju (1608-49), the pioneer expounder of Oyomei, was popularly known as "the living Confucius." Another champion of Oyomei has left a superb monument in his engineering feats of irrigation, but had to suffer for alleged heresy and died officially disgraced, in exile. The Japanese thinkers went further in their conception of cosmic force, and using the modes of thought so long in use among the Zen (contemplative) sect of Buddhists, they reached conclusions, curiously akin to those of the modern evolutionists, which prepared the way for the enormous vogue in recent years of the Occidental theorists in the physical sciences. The dragon was their favorite symbol of the supreme power of the universe. They sought, even to penetrate behind the mask, which change imposed on all things. In spite of the hostility of the orthodox academicians in Yedo and the terror of the censorship, the new ideas of Oyomei, which called for a reconstruction of society and government, steadily gained ground. Satsuma, Chōshū, Hizen, Tosa, the provinces whence

nearly all the great statesmen of modern Japan have arisen, formed the stronghold of this philosophy, while in Echizen, Yokoi, who sent the first students to America, was its chief expounder. Most of the generals and admirals, distinguished in the wars with China and Russia, were brought up in the Oyomei philosophy. Action, which looked to political reconstruction, began at Osaka in 1837, when Oshiwo, a famous Oyomei scholar, led a revolt, which in time of famine opened the granaries to the starving poor. While Bushido (q.v.) was taught only for practical benefit and never became a philosophy, Oyomei fed the men who hungered for intellectual justification of their protests against the Yedo despotism and of their actions, technically lawless but inherently righteous. Their proceedings, in overthrowing dualism, restoring the Mikado's supremacy, abolishing feudalism, tolerating Christianity and granting freedom of conscience, were all, in their minds, the logical result of Oyomei, which thus demonstrated its true nature. At the antipodes of the quietism and conservatism, both of the archaic and the neo-Confucianism, Oyomei meant stimulus, progress, an alert mind that welcomes the new, when it is demonstrably true, and confesses fault when discovered, even in the old ideas and time-honored custom. Nothing so explains the cause and reason for the New Japan, excelling in potency by its interior force all foreign influences, as does this intellectual discipline, begun nearly two centuries before Commodore Perry, and which gave the nation its new mind. Yet even in this history, the trend of the true genius of Japan is discerned—which is ever impatient with the abstract and is eager for the practical. Oyomei, as expounded in Japan, transformed mediæval Confucianism into an immediate working principle for the individual, while calling for a vital relation between knowledge and action. In this light, Japan is no "enigma," and the Japanese are not "Oriental," according to vulgar ignorance or associations, but are normal. See WANG YANG-MING.

E., 'The Japanese Nation in Evolution' (1907); Knox, 'Transactions of the Asiatic Society of Japan' (Vol. XX); Okakura, 'The Awakening of Japan' (1904); Armstrong, R. C., 'Light from the East; Studies in Japanese Confucianism' (Toronto 1914).

OYSTER BAY, N. Y., town in Nassau County, on the north coast of Long Island, on an inlet of Long Island Sound, and on the Long Island Railroad, about 15 miles east of New York and 28 miles from City Hall. It is connected by steamers with New York and the large sound ports. Its name comes from its principal industry—cultivating oysters. It is a favorite watering-place. Sea Cliff, (Pop. 2,108) and Farmingdale (Pop. 2,091) are villages in the town. Contains the home of late ex-President Roosevelt. The government is administered by town meetings held biennially. Pop. exclusive of Sea Cliff and Farmingdale, 16,097.

OYSTER-CATCHER, a shore-bird of the plover family, several species of which constitute the genus *Hamatopus*. The bill is of great length, pentagonal at its base, slightly bent upward and flattened or compressed at the apex, which is truncated. Oyster-catchers fre-

quent both sea-coasts and inland waters, picking up small mollusks, crustaceans, sand-worms, etc. They are 18 to 20 inches long, and their plumage is handsomely variegated with black, white and brown, so that the Old World species (*H. ostralegus*) is often called "sea-pie" in England. The familiar American species is *H. palliatus*, it is white below, blackish brown on top, with a band of white on the wings. It is to be found in all parts of the country, but is rare northward of the middle parts. Consult Elliot, 'North American Shore Birds' (1895); Newton, A., 'A Dictionary of Birds' (London 1896); Sandys and Van Dyke, 'Upland Game Birds' (1902).

OYSTER-CRAB, or **PEA-CRAB**, a small crab (*Pinnotheres ostreum*) which dwells inside of the shells of American oysters as a commensal (see COMMENSALISM). Other species inhabit other host-shells in various parts of the world, one associated with a Mediterranean *Pinna* being the subject of some pleasant classical legends. These small crabs are excellent eating, but the difficulty of getting them in any considerable quantity makes them a costly dainty.

OYSTER-FISH, a local name for the tautog (q.v.).

OYSTER PLANTS, VEGETABLE OYSTER, SALSIFY, or SALSIFY, a biennial composite herb (*Tragopogon porrifolius*). When in flowers it is about four feet tall, bears grass-like leaves and showy, purple flowers, which close before noon. It is a native of Europe, whence it has spread as a weed to many countries. The cultivated varieties are grown for their gray tap-roots, which are often a foot long and two inches in diameter, and which suggest the flavor of oysters. The seed should be planted in deep, rich, well-drained soil as early in the spring as the ground can be worked, the drills being 15 or 18 inches apart. The plants must be cleanly cultivated until their tops cover the spaces between the drills. In late autumn part of the crop should be dug, the remaining part being allowed to stay until spring. Freezing does not harm the roots; indeed, they are believed to be better flavored if so treated. The stored roots are very apt to shrivel, become tough and lose flavor. Cool, moist storage, or pits, or especially burial in dry, clean sand obviate this difficulty. The plant succeeds best in cool climates and should be in every home garden. As a commercial vegetable it is of far less importance than parsnips and carrots.

OYSTER-SHELL BARK-LOUSE. See SCALE INSECTS.

OYSTERS, lamellibranch or bivalve mollusks of the family *Ostreidae*, more strictly, edible species of the genus *Ostrea*, though the name is sometimes applied to other *Pelecypoda*, as the hammer oysters and pearl oysters of the family *Aviculidae*. In the true oysters (*Ostrea*) the shells are irregular, the two valves unequal and the hinge without teeth. The animal is attached to some submerged object by the left valve, which becomes hollowed out to receive the body, while the right valve, which is free, is flattened or may be even concave from above. The shells are closed by a single adductor muscle, popularly called "heart," which extends

from about the centre of one valve, through the animal, to the other. The edges of the mantle are free from each other and are fringed upon the margin. The gills (called "beard" in cook-books) are nearly equal and coherent dorsally, and the labial palpi are triangular. The oysters are peculiar in that the intestine does not run through the heart, which lies anterior to the muscle, while the foot is small or even entirely absent, a result of the sedentary life.

About 70 recent species of *Ostrea* are recognized, mostly inhabitants of the warmer seas. The most important species are the common oysters of Europe (*O. edulis et al.*), the *Ostrea virginiana* of the eastern coast of America, and the Japanese oyster (*O. cucullata*). The first-mentioned species occur from Norway and the Baltic to England and into the Mediterranean, another species of less importance (*O. adriatica*) taking their place in the eastern Mediterranean and the Black Sea. At one time *O. virginiana* ranged along our whole eastern coast, from the Gulf of Saint Lawrence to the Gulf of Mexico, and was used extensively by the Indians, but since the growth of civilization there it has disappeared from the whole coast between Nova Scotia and Cape Cod. There still remain beds in the Bay of Chaleurs and around Prince Edward Island. It has been introduced at points on the Pacific Coast. On the Pacific Coast two native species are eaten, *O. conchophila* of California and *O. lurida* of the coasts farther north. In the tropics species belonging to the subgenus *Alectryonia* become attached to the roots of the mangroves and are exposed at low tides; these are the so-called "tree oysters" or mangrove oysters.

Oysters, like all other mollusks, reproduce exclusively by eggs. Our *O. virginiana* has the sexes separate, but the European oysters and one of the Pacific species are hermaphroditic. The Eastern oyster is very prolific, producing from 10,000,000 to 60,000,000 eggs. Fertilization takes place by the admixture of the ova and sperm in the water. From the eggs there hatch out small, free-swimming larvæ, which swim about until after the first appearance of the shell, and thus aid in the distribution of the species. They swim by means of a ciliated velum or foot, and the valves of the horny larval shell are symmetrical like those of a clam, while the single muscle uniting them is not the same as that which appears in the adult. After a few days this free life ceases and the young become attached by the left mantle fold, which secretes a limey deposit at its margin. They are known as "spat" and grow rapidly, feeding upon the microscopic life in the water which is conveyed to the mouth by the cilia covering all parts of the body, and especially the gills and labial palpi. When large enough for transplantation the young are termed "seed oysters." As will be seen from the foregoing, the oyster needs some solid support upon which to attach itself, otherwise it would sink in the mud and become smothered. In nature this support is furnished by reefs of rocks or by banks of old oyster shells.

On the natural oyster beds a very small percentage of the eggs is ever fertilized and vast numbers of the swimming larvæ are destroyed by failure to secure attachment, or by being swallowed by certain surface-feeding

fishes or by numerous lower animals which, like the adult oysters, sweep their food into the mouth by ciliary action. Many young oysters are destroyed by a host of enemies that prey upon them; others are suffocated by luxuriant plant and animal growths, including older individuals of their own species, or by sedimentary deposits; sudden freshets kill great numbers; storms tear them up and cast them ashore, and those which, like the "raccoon" oysters, live on tidal flats are sometimes destroyed in great numbers by ice in the winter or by too long exposure to the sun's rays in summer. Notwithstanding all this destruction the oyster is so prolific that, except along the New England coast north of Cape Cod, where a change in physical conditions has proved detrimental to its existence, the beds have continued to extend until subjected to the destructive influence of the white man, and have become the foundation for the development of a mutualistic fauna and flora almost as rich, varied and complex as that of a coral reef.

Culture.—As long as the market for Eastern oysters was limited to a relatively narrow belt along the seaboard, and before the population of some parts of this region had reached its present congested state, the extensive natural beds of Chesapeake Bay and other parts of the coast afforded a sufficient supply. Increasing demand long since led to over-fishing, which menaced the natural beds and compelled the development of new ones by planting suitable barren bottoms, often in regions where the oyster does not naturally breed. Extensive acreage has thus been developed and rendered productive, especially in Long Island Sound and other regions where suitable riparian laws secure the rights of private ownership. Attempts to establish close seasons and similar legislative devices have proved of little avail and have generally led only to more intensive harvesting during the open season. With the further widening of the market, due to improved transportation facilities and the introduction of the refrigerator car, the demand has severely pressed upon all sources of supply. This healthy condition of the oyster industry has stimulated a serious interest in the problems and possibilities of oyster culture and has led to the survey of suitable grounds for planting, from New Jersey to Texas. Vast neglected areas in the shallow bays and sounds along many parts of our coast could, by intelligent preparation and planting to oysters, be transformed from unproductive mud banks into rich sources of food supply and revenue. But no one should venture into this field without a full understanding of the complex biological and physical factors involved. To do otherwise is to invite disappointment and financial loss.

The successful maintenance of planted oysters is dependent upon the proper consideration of the character of bottom, the depth, temperature and density of the water, the food supply for the growing oysters, the rate of sedimentation and the methods of collecting the marketable oysters, combating enemies and many minor matters.

Selection of a suitable bottom is of prime importance, and the ideal condition is found in one presenting a firm substratum of stones or clay covered by two or three inches of loose organic mud. The first furnishes a foundation,

the latter a suitable nidus for the growth of the minute organisms which constitute the oyster's food. Rocky, clayey or sandy bottoms are generally poor food producers, and the latter are peculiarly liable to shifting by currents, with a resulting burial and destruction of the oysters. Deep, soft mud engulfs and suffocates the oysters. Too rapid a deposition of sediment has the same result and is especially fatal to young and small oysters.

As indicated by their extensive geographical distribution oysters naturally withstand a range of temperature from below freezing to above 90°, but when subjected to these extremes they undoubtedly deteriorate and in time succumb. In common with other organisms oysters grow most rapidly in warm waters and find their optimum temperature between 60° and 70°. If it be desired to establish self-perpetuating beds it is important that the temperature should reach an even higher point during the summer in order to stimulate natural reproduction. Being naturally brackish water animals oysters do not thrive in water of full sea salinity and become of very poor quality when the percentage of salts falls too low. In commercial quantities they inhabit water of densities between about 1.008 and 1.022. It is important to so locate beds that they shall be free from inundating freshets. While oysters are generally planted in shallow bays and coves at depths of from one to five or six fathoms luxuriant natural beds are found from above low water to a depth of 20 fathoms, and in Long Island Sound planting is practised to 15 fathoms.

The food of oysters consists of a great variety of minute animals and plants, protozoans, the eggs and swimming larvæ of many kinds of sponges, worms and mollusks, including their own, the spores of algæ and especially the minute plants known as diatoms. The latter live in enormous numbers on the surface of the mud in shallow bays, and during warm weather multiply with great rapidity. As they constitute the bulk of the oyster's food the importance of determining their abundance in advance is self-evident. The other organisms chiefly belong to the associations that become established on the oyster beds and their occurrence need not be so carefully predetermined. It is possible to establish highly successful beds at some distance from the diatom garden if strong tidal or other currents pass from the latter to the former. The existence of such currents is beneficial in many other ways also than as food carriers. They sweep the beds clean of sediment, ensure a ready supply of oxygen and increase the fecundity of the beds by bringing the ova and spermatozoa in contact and by carrying the young swimming spat to suitable places of attachment.

All of these conditions having been satisfactorily determined and the site for a bed located the planter first marks its boundaries by stakes or buoys. The bottom is then smoothed and cleared of snags and débris either at low tide or by means of tongs or dredges according to the depth. If the bottom is covered by more than an inch or two of mud it is prepared by strewing it with an even layer of shells, gravel, slag, cinders or similar material. These furnish a foundation, and, if the bed be suitably related to a spawning ground, serve at the same

time as a "clutch" on which the spat will settle. In this case nothing further need be done but to await developments and care for and protect the beds. But if this is not the case young or "seed" oysters must be provided. These are usually from one to one and one-half inches in diameter and are obtained either by dredging the gravel and shells from natural beds or by spreading on the bottom suitable shells or other "clutch" to collect the spat; when they are raised and spread over the prepared bottom, usually to the extent of 300 to 600 bushels per acre. While very soft bottoms are usually unfavorable for planting they may sometimes be prepared by covering with a layer of brush and it is probable that either by this method or by building open platforms many such places will be utilized in the future. From one to four years, depending on the richness of the food supply, are required to mature sea oysters. In order to make a portion of the supply available each year the bed should be staked off into three or four sections, only one of which is dredged annually, the others remaining undisturbed to collect spat and mature their growth.

Among the teeming life of the oyster beds are found many plants and animals which are more or less destructive, especially to the young and thin-shelled oysters. Strong growths of eel grass and algæ, as well as boring sponges and similar animals, should be kept in check by mowing or dredged and removed when necessary. A more serious pest is the gastropod mollusk (*Urosalpinx*), which perforates the shells and destroys young oysters, especially southward; starfishes, which often sweep over the Long Island Sound beds in such vast armies that all but the very largest oysters are devoured; and drumfish and stingrays, the former of which creates great havoc in New Jersey, the latter in California. Strong stockades of stakes are a sufficient bar to the larger fishes. Prompt and energetic use of great mops in which they become entangled will greatly reduce the number of starfishes, which can be used as fertilizers on the land. Large numbers of drills may be captured by the use of an ingenious box dredge provided with a screen cover which excludes the oysters while the drills drop through its meshes into the interior. Certain sponges and annelids also injure the oysters.

For a few weeks previous to marketing many oyster farmers transfer a portion of their crop from the beds in deeper waters to warm shallows, where the greater abundance of food causes them to fatten and improve in flavor. Such oysters are highly esteemed and have an enhanced value. This process must not be confused with "plumping," which, though also known as fattening, consists simply in changing the oysters to waters of a lower density for a few days. As a result they absorb water and become bloated. They gain nothing in nutrient value and deteriorate in flavor, but appearing plump and full find a ready sale at a higher price.

While the practicability of some forms of pond culture in the United States has received experimental demonstration and enormous possibilities for future extension of the oyster industry by this means are indicated, the demand has not yet led to the employment of the capital required for its development on a commercial

scale. Important advantages of pond culture lie in the possibility of increasing fecundity by artificial propagation and more efficient collection of the spat, the control of the food supply and the exclusion of enemies. The immediate prospects are that the next practical step in the development of oyster culture in this country

resulting from decay or from pollution or otherwise. One of the forms of greenness to which oysters are subject is due to the presence of copper, and appears to be damaging to the quality of the oyster, if not actually poisonous.

Recent available statistics of oyster production are here tabulated:

	United States		Atlantic Coast		Gulf Coast		Pacific Coast	
	Pounds	Value	Pounds	Value	Pounds	Value	Pounds	Value
Oysters, market, from public areas.....	103,641,000	\$4,416,000	72,413,000	\$3,303,000	31,225,000	\$1,112,000	2,300	\$800
Oysters, market, from private areas.....	74,652,000	8,305,000	64,642,000	7,239,000	7,956,000	381,000	2,055,000	686,000
Oysters, seed, from public areas.....	26,960,000	1,035,000	22,436,000	948,000	4,522,000	87,000	1,800	200
Oysters, seed, from private areas.....	28,056,000	1,957,000	27,252,000	1,944,000	700,000	6,200	104,000	6,500
Total oysters.....	233,309,000	\$15,713,000	186,743,000	\$13,434,000	44,403,000	\$1,586,200	2,163,100	\$693,500

will be in the direction of raising in artificial enclosures seed oysters for planting beds on natural and prepared bottoms.

Cultural methods have attained a high degree of perfection in various European countries, especially in France and Holland, and in Japan. In France *O. edulis* and allied species are cultivated in oyster parks. The "spat" is collected on fagots of brush, tiles or other collectors placed in proximity to spawning beds. The "seed" oysters are then removed to partially enclosed growing-ponds admitting the tides through sluices and flood-gates. When fully grown they are fattened and flavored in small enclosed ponds or "claires." While in these their diet of diatoms gives them a green color that is no sign of inferior quality. While some of these refined methods will doubtless serve as the basis of a future oyster culture on parts of the Atlantic seaboard, the simpler Japanese methods seem better adapted to the culture of the oysters of our Pacific Coast. The oyster culture of Japan reaches its highest development in the Inland Sea and is concerned chiefly with *O. cucullata*. As in France, the exact methods employed differ greatly with the locality, but in general the farms are in shallow brackish waters, where the great tidal rise and fall leaves large areas exposed at low water. They are laid out with reference to the direction of the currents, topography of the bottom, etc., and each is enclosed by a bamboo fence or hedge. This area is then planted with bamboo stakes stuck into the ground and variously laid out in straight parallel fences with suitable alleys and aisles or in groups arranged in rows, circles, etc. These serve to collect the spat and to hold the growing oysters. In districts where growth ceases in two years two sets of fences arranged alternately are employed, one set being culled and rebuilt each year. In other districts the oysters are moved annually from shallow into deeper water until the end of the third or fourth year, the shallows near the shore being employed for spat collection, the moderate depths for growing bottoms and the deeper waters of each farm for fattening.

Oysters appear under certain conditions to be poisonous, whether on account of ptomaines

About five-eighths of these come from artificial beds.

In the United States oysters are collected from the beds, whether natural or artificial, in two ways. In the shallower waters they are taken by means of oyster-tongs, which are like two long-tined rakes, hinged so as to open and close like shears. In deeper water (down to 15 or 20 fathoms) recourse is had to the dredge worked by steam or sail boats. This is a rectangular iron frame-work, about four feet across, with sharp edges, or with long teeth upon one side, while attached to the other is a large open-work bag of cord or iron. This dredge is dragged over the bottom, the teeth or sharp edges tearing the oysters loose, when they are caught in the bag and brought to the surface. See also PEARL.

Bibliography.—The importance of the oyster industry has led to the development of an extensive literature to which the following, chiefly government publications, are introductory: Brooks, W. K., 'The Oyster' (Baltimore 1915); Brooks et al., 'Report of the Oyster Commission of the State of Maryland' (Annapolis 1884); Dean, 'Present Methods of Oyster-culture in France' (Bull. U. S. Fish C. 1890); Dean, 'European Methods of Oyster-culture' (ib. 1891); Dean, 'Japanese Oyster-culture' (ib. 1903); Huxley, 'Oyster Industry of England' (*English Illustrated Magazine*, Vol. I); Ingersoll, 'The Oyster Industry' (Tenth Census Report, 1881); Kellogg, J. L., 'Shell-fish Industries' (New York 1910); Moore, 'Manual of Fish-culture' (Washington 1897); Moore, 'Report on Oyster Beds of Louisiana' (Rep. U. S. Fish Com., 1899); Ryder, 'Principles of a Rational System of Oyster Culture' (ib. 1886). Numerous additional biological, cultural and statistical papers may be found in the publications of the United States Bureau of Fisheries, including in the earlier volumes some translations of important papers by European authorities. The commissions of Maryland, New Jersey, etc., have also issued important reports, generally of more local interest.

OZÆNA, a discharge of fetid, purulent or sanious matter from the nostrils. It is a symptom rather than a disease, and may arise from

ulceration of the membrane lining the nostrils, or from caries of the adjacent bones.

OZANAM, ō'zā'nān', Frederick, French author, professor and philanthropist: b. Milan, 23 April 1813; d. Marseilles, France, 8 Sept. 1853. He was the second son of an eminent physician, Antoine Ozanam, a descendant of a long line of scholars and scientists and of Jewish extraction. Soon after the birth of Frederick, the family returned to their native city, Lyons. Great care was exercised in the early education of the boy. The teacher who exerted the most influence over young Ozanam was Abbé Noirot. He was the youngest of 130 pupils; but nearly all the time he was a pupil in this famous school he led his class. He was well versed in the grammar and literature of English, German, Hebrew and Sanscrit, and was one of the eminent French scholars of the time. At an early age his writings attracted the attention of such men as Lamartine and his associates. After finishing his college course he began the study of law. It was while a law student in Paris that he formed the acquaintance of and became friends with Marie Ampère, the mathematician; Chateaubriand (q.v.); Lacordaire (q.v.), and a number of the writers and professional men of France.

His first public work was an attack on the doctrines advanced by the Saint Simonians. In reply to Ozanam's attack on their doctrines, the Saint Simonians accused the followers of Ozanam of doing nothing but advance theories. In May 1833, Ozanam and a few chosen companions held a meeting to consider ways and means of combating the Saint Simonians. At the suggestion of Ozanam it was resolved that they should unite in giving personal service "to God in the persons of the poor, whom they were to visit at their own dwellings and assist by every means in their power." This meeting was really the beginning of the Society of Saint Vincent de Paul (q.v.). The members of this new organization were to do more than give alms; they were to place their intelligence, their education, their special knowledge of law and science, and their general knowledge of life, at the disposal of the poor.

Ozanam is regarded as the founder of the now great Society of Saint Vincent de Paul; but he always, in his humility, repudiated the title of founder. "We were eight," he would say. He was one of the first, if not the first, to introduce Dante to the French people. His thesis on Dante when, in 1838, he went up for the degree of doctor of laws, electrified Paris. His audience wept, applauded and at the close rose *en masse* and expressed their appreciation. He was only 26 years of age when he was appointed to the municipal chair of law in Lyons. Later he accepted the chair of foreign literature at the Sorbonne. When he began his work at the Sorbonne he was 27 years of age and had just been married. His work here showed that he was a master among instructors, a leader among students of literature; but his great aim was "to make men of his pupils," to impart to them manliness, vigor and love of work.

In 1843 he was one of the group who founded the literary association called the "Cercle Catholique." Some of those interested

in this movement were Lacordaire, Montalembert (q.v.), De Ravignan and Bautain. Ozanam was made president. His speech on the literary duties of Christians was one of the great attractions of the first year. He shone as a scholar and an orator, defending the Catholic Church against its opponents with great vigor, and he was recognized as a most industrious student; but he is best known to-day for his personal service to the poor and the ignorant and his advocacy of the work of the Society of Saint Vincent de Paul. His best-known books are 'Les Poètes Français'; 'Dante's Divina Commedia' ('Les Germaines.' Consult O'Meara, 'Life and Works of Ozanam'; 'Letters of Ozanam.')

OZARK (ō-zārk') MOUNTAINS, a plateau region, from 1,200 to 1,800 feet above the sea-level, extending with gradual upliftings from the southern part of Illinois into Missouri, then sloping down enters Arkansas and Indian Territory and extends into Kansas. The highest point is Pilot Knob, in Iron County, Mo. The hills are in separate peaks or knobs, and not in continuous ridges. The irregularities which show mountain-making processes as existing are not visible here; the Ozark Mountains or Ozark Plateau belong with the oldest mountain regions of the world, and denudation is slowly and surely removing the last remnants of once lofty mountains. A small area of Precambrian rocks is exposed in the Saint Francois Mountains; the remainder of the plateau consists of rocks of Cambrian and Ordovician Age. The region was probably peneplained in Tertiary time, and has since been uplifted and dissected. On the southern slope are large forests.

OZOCERITE, ō'zō-sē'rīt, a mixture of the solid hydrocarbons left behind by the evaporation of petroleum *in situ*. It is wax-like, occasionally with a fibrous structure, and usually consists of an aggregate of minute doubly-refracting needles. Fracture often conchoidal. Ozocerite varies in consistency from that of soft putty to that of beeswax. The melting point varies from 50° to 90° C., and attains the maximum value in the best material. The specific gravity is 0.9-0.98. The color by reflection is greenish or yellowish brown, green or black; by transmitted light a thin lamina appears brown or reddish brown. Ozocerite is often found together with petroleum, and as an impregnation or in fissures in sedimentary rocks. It is found in largest quantities in Galicia, Rumania, Baku and Utah. The Gallician mines were formerly worked by hand, but now employ electrical power. The methods of extracting the wax vary from hand-picking to the use of boiling water. The resulting wax is refined by sulphuric acid and charcoal, and is known as ceresine. It is used to adulterate beeswax; to make candles for hot countries, oils, and a substance like vaseline, as an electrical insulator, and to polish the heels and soles of shoes. The annual production of ozocerite in Galicia is about 2,650 tons. See ELATERITE; HATCHETTITE.

OZONE. See LIQUEFIED AND COMPRESSED GASES; ALLOTROPY.

P

P the sixteenth letter of the English and various other alphabets, is the sharp labial consonant pronounced when, the lips being closely compressed, they are separate by a forcible emission of the breath. Like *k* and *t*, it is a pure mute or surd, involving no action of the vocal chords: it differs from *b* in that *b* is sonant: with the same compression of the lips as in *p*, the effort to pronounce *b* involves the vibration of the vocal cords. The form of this letter, *P*, comes from the Latin alphabet: the same speech element is called *pi* in Greek and its form is *π, η*, while in the Greek alphabet our character *P* is called *rho*, equivalent to *r*. In early Phœnician writing the element *p* was represented by a vertical stroke curved or crooked to the left at the top (𐤐): this form was also used in early Greek, but with crook directed to the right, (𐤑): afterward the crook was made angular, (𐤒), and finally the two downward strokes were made of one length (π). In early Latin the *p* had the form (𐌒) which finally became *P*. The surd labial *p* is freely interchanged with *b*, *f* and *v*, for they are all of the class of labials and dentilabials.

Languages springing from a common original differ from one another in the preference they show for *p*, *b*, *f* or *v*. The English language has very few words of Germanic origin beginning with *p*: such words in English are nearly all of Latin, Greek or Celtic origin. Latin *p* by Grimm's law (q.v.) corresponds to English *f*, as *pater* (*father*). English *p* corresponds to Latin *b*, as *lip*, cognate with *labium*. In German very many words of Latin origin, as *palatinatus* (from *palatium*), *papa*, *palus* (stake), *persona* (parson), *pavo* (peafowl), *præbenda* (prabend), *piper* (pepper) become *pfalz*, *pfaffe*, *pfal*, *pfarrer*, *pfau*, *pfründe*, *pfeffer*, etc. The digraph *ph* was originally used by the Latins to represent the sound of the Greek letter *phi* (Φ, φ), which must have been different from the sound of the Latin letter *f*; else the Greek words *philosophia*, *pharmakon*, *phonaskos*, etc., would have been written *filosofia*, *farmacum*, *fonascus*, as the modern Italians write everywhere *f* for *ph*—*filosofia*, *fisica*, *Filomena*, etc. There are no native English words beginning with *p* followed by *n*, *s* or *t*; but there are many such words of Greek origin: in those words the *p* is silent. The *p* between *m* and *t* in *attempt*, *contempt*, etc., is introduced to facilitate the utterance of the *m*: but in such words as *exemption* (exemshun), *redemption* (redemshun), etc., there is no need of this mediating *p* and it is silent in correct pronunciation. See ALPHABET; PHONETICS.

PABRIANICE, pā'bya-nyē-tsě, Poland, a manufacturing town in the district of Piotrkow,

10 miles southwest of Lodz, with which it has communication by means of an electric railway. Paper and agricultural implements are manufactured and there are also textile mills. Pop. 39,000.

PACA, pā'ka, William, signer of the Declaration of Independence: b. Wye Hall, Hartford County, Md., 31 Oct. 1740; d. there, 1799. He studied at Philadelphia College, where he was graduated in 1758, and in the Middle Temple in London; practised law in Annapolis; became a patriot leader; was a member of the legislature 1771-74, of the committee of correspondence 1774, of the Continental Congress 1774-79, and of the State senate 1777-79. His career as judge began in 1778, when he became chief judge of the Maryland Superior Court; from 1780 to 1782 he was chief judge of the Court of Appeals for Admiralty and Prize Cases. In 1782-86 he was governor of the State; in 1788 was a member of the State convention which ratified the Federal Constitution; and for the last 10 years of his life was United States district judge. His wealth and influence had been lavishly given to the Revolutionary cause, and he more than any one man perhaps overcame the opposition in Maryland to that cause.

PACA, a large agouti-like animal (*Cælogenys paca*) of eastern South America, robust in form, with a broad, swollen head, caused by the great expansion of the zygomatic arches, and large eyes and ears. It is about two feet long and a foot tall; the tail is a mere rudiment and the color brown, marked with rows of oblong whitish spots. It lives near water in which it is much at home and digs shallow burrows in which a single young one is produced annually. It remains hidden by day and seeks its plant-food by night, often making destructive forays upon plantations, especially of sugarcane. The flesh is edible and the hide is useful for leather. Another less common species is recorded.

PACAY, pa-kā', a Peruvian leguminous tree (*Prosopis juliflora*) related to the mesquite. The pure white, flaky matter in which the seeds are embedded is used as food, and the pods, which are nearly two feet long, serve for feeding cattle. A gum, called mezquit gum, is also obtained from the plant. The name *pacay* is also applied to *Inga Feuilli*, another Peruvian leguminous plant.

PACCANARISTS, a religious congregation of the Catholic Church, founded in Rome, in 1797, under the name of Regular Clergy of the Faith of Jesus, by Nicolao Paccanari, by whose name they came to be known popularly. The founder intended the congregation to carry on the work of the Jesuits, just then sup-

pressed, but upon the re-establishment of the latter in 1814 the Paccanarists were merged with them.

PACCARITAMBO, pāk-kā-rē-tām'bō, or **PACCARITAMPU**, Peruvian cave south of Cuzco, on the Vilcamija River, reputed among the Incas as the place where Manco Capa and his brothers appeared first on earth, and styled "House of Dawn," in Quicha Paccaritampu.

The same idea is prevalent in numerous mythologies of the American Indians. The sun came out of a cave in the morning and went into one in the evening. As the Peruvian upper classes of pre-Columbian days claimed that they were the children or descendants of the sun, they designated their starting place as the "House of the Dawn." This was symbolical and equivalent to saying that they came from the realms of the sun. The place from which the sun people came into Peru, according to the commonly accepted tradition, also became commonly known as the Paccaritampu or "House of the Dawn" or beginning.

PACCHIAROTO, pak-kē-ä-rō'tē, **Jacopo**, Italian painter: b. Sienna, 1474; d. France, 1540. When a boy he showed a taste for devotional art and was placed in the studio of Bernardino Fungai, a Siennese artist of contemporary fame. In 1535 he headed a conspiracy against the government of the city and after concealing himself in a grove fled for his life to France, where he worked under Rosso, the famous Italian painter, sculptor and architect, who had been invited to court by Francis I. While his main works in fresco and oil are at Sienna, his 'Saint Francis of Assisi' and 'Madonna and Child' in the Munich Pinakothek are among the gems of that collection. His style shows the influence of Perugino, and possibly of Raphael (q.v.). According to some authorities, the better of the works attributed to Pacchiaroto are really due to one Girolamo del Pacchia, while Pacchiaroto's work was at best mediocre.

PACCIOLI, pa-chō'lē, **PACIOLI**, or **PACIUOLO**, Luca de Borgo, Italian mathematician: b. Borgo San Sepolcro, Tuscany, about 1440; d. about 1515. He traveled in the East in his youth and joined the Franciscan Order. He became famous as a teacher of mathematics in Florence, Rome and Venice. He wrote 'Summa de Arithmetica, Geometria, Proportionione et Proportionalita' (1494; 2d ed., 1523), which covered completely the mathematical field of his day and was the first great work on mathematics after the Latin Euclid of 1482. Fra Luca is considered the inventor of bookkeeping on modern or quasi-modern lines.

PACE, a measure of length, used as a unit for long distances. The Latin pace was measured from the mark of the heel of one foot to the heel of the same foot when it next touched the ground, thus stretching over two steps; while the English pace is measured from heel to heel in a single step. The Latin pace was somewhat less than five feet; the American military pace at the ordinary marching rate is two and one-half feet and at double-quick time three feet. The pace, measured separately for each individual, is the usual working unit in the construction of military maps in the field.

PACER. See HORSE, TROTting AND PACING.

PACHACAMAC, päch-ä-kä'mäk, ruined city and temple in the district of the same name in Peru. The village now occupying the site is called La Mamacoma and is the terminus of a railway from Lima, 20 miles to the northwest, and is situated near the Rio de Lurin. The ancient city, a sacred city and quasi-Mecca of both the Incas and the earlier Yuncas, was devoted to Pachacamac, the supreme god and creator of all in the Yunca theogony, and in the time of the Incas to a temple of the sun. The outlines of the old city are clearly visible; it had broad, regular streets and its entire site, a lofty hill, projecting out to sea, was elaborately terraced. On its top was the temple of Pachacamac, about 200 yards long and 150 wide. A cemetery surrounds this temple and is very rich in remains of the pre-Incan civilization, especially household utensils, which were buried with the flexed corpses. The Inca convent on lower ground is an adobe building, 116 yards long and 67 wide and contains 18 cells. The remains of tiny huts at the foot of the hill probably point to pilgrimages to these shrines, being no doubt inns for the entertainments of the pious visitor. Pizarro sacked the shrine in 1523, destroyed a wooden idol and it is said carried away 1,700 pounds of gold and 1,600 of silver. Consult Squier, 'Peru' (1853); Uhle, M., 'Pachacamac' (Philadelphia 1903); Wiener, 'Pérou et Bolivie' (1880).

The district of Pachacamac is an administrative division of the province and department of Lima, with about 1,300 inhabitants. The same name is borne by an island off the coast of Peru near Lurin.

PACHECO, Francisco, frän-thēs'kō pä-chä'kō, Spanish painter and writer on art: b. Seville, 1571; d. there, 1654. As a theorist in the art of painting Pacheco occupies a unique position in the history of the Seville school. His pictures are elaborate in their skilful embodiment of the principles he expounded in his 'Arte de la Pintura' (the Art of Painting). His treatise, however, did much for art in Spain, and he was the master of both Alonzo Cani and Velasquez, the latter of whom became his son-in-law. In his 'Last Judgment' (painted for the nunnery of Saint Isabel) he introduced his own portrait, and ambitious and learned as many of his pictures are his small portraits, some of them in crayon, are among the best of his works. Good examples are to be seen in the two churches at Alcalá de Guadaira near Seville and in the Madrid picture-gallery.

PACHMANN, päh'män, **Vladimir de**, Russian pianist: b. Odessa, 27 July 1848. He studied music with his father, an amateur violinist and with Dachs at the Vienna Conservatory; made his first appearance in 1869; after eight years of retirement made his first tour; again retired for two years; in 1882-83 played successfully in Vienna, Paris and London; came to the United States in 1890; and toured in 1899 and 1900.

PACHOMIUS, pa-kō'mī-üs, **Saint**, Egyptian ascetic of the 4th century: b. Thebaid, about 292; d. Proii, Egyptian Thebaid, about 348. In early life he was drafted as a conscript in the army of Maximin and at Thebes met Christians, whose teaching so interested him that on the conclusion of the campaign of Maximin against Constantine and Licinius he was baptized and

embraced the life of an anchorite. His guide in his choice was Palemon, who accompanied him to Tabenna, an island in the Nile, where they took up their residence. In 326 he founded the first monastic community and he is spoken of by the learned Tillemont as "the institutor not only of certain monasteries, but of the conventual life itself, and of the holy communities of men devoted to religious life." His sister is said to have founded the first convent. The movement spread rapidly and according to Palladius (q.v.) at their death their monastery and convent contained 7,000 inhabitants. (See MONACHISM). Consult Amehneau, 'Étude historique sur Saint Pakhôme et le cenobitisme primitif dans la Haute Égypte' (Paris 1887); Grützmacher, 'Pochomius und das älteste Klosterleben' (Freiburg 1896); Ladewze, P., 'Le cenobitisme pakhomien' (Louvain 1898).

PACHUCA, pā-choo'kā, Mexico, capital of the state of Hidalgo, 68 miles by railway north-east from the City of Mexico; elevation about 8,000 feet above the sea. Three railways—the Hidalgo and branches of the Mexican and Mexican Central—supply transportation facilities. The Sierra Madre Oriental rising on three sides form an amphitheatre in which the city is situated and from which it looks out toward the southwest upon a rich and highly cultivated plain. These mountains are honeycombed with producing mines down to the very door of the city itself, within the boundaries of which are several important establishments for treating ores, some of which have been in operation since the early days of mining in this district. The mountains behind the city form the northeast boundary of the valley of Mexico and within their shadows is produced almost or quite one-third in value of the annual output of Mexico. The city is essentially a mining community and is not especially noted for any other industry. It has a strong financial institution—the Bank of Hidalgo—with a capital of \$1,000,000, a branch of the National Bank and an agency of the Bank of London and Mexico. There are two public libraries, containing together over 5,000 volumes, and a number of churches and schools. Bartolome de Medina, who in 1557 discovered the patio process of amalgamating ores, which is still largely in use by Mexican miners, lived in Pachuca. Pop. about 37,000.

PACHYDERMATA, pāk'i-dēr'ma-ta, the name formerly applied to a division or order of mammalia including the elephants, tapirs, hippopotamus, rhinoceros, swine and hyrax—all of which forms were distinguished by their thick skin, by their non-ruminant habits and by their possessing more than one hoof on each leg. This classification has, however, given place to a more scientific and natural arrangement, in which the several forms are placed according to fundamental structural affinities. Thus the elephants form a distinct order, the *Proboscidea*. The rhinoceros and tapirs are included in the division *Perissodactyla* of the ungulate order; the hippopotamus and swine are arranged in the section *Artiodactyla* of the same order; while the hyrax has a separate order—*Hyracoidea*—to itself. See *UNGULATA*.

PACIFIC OCEAN, also formerly called the *SOUTH SEA*, the largest of the five great basins of the hydrosphere, extending for 133° of latitude and 180° of longitude, between the

west coast of the North and South American continents and the east coast of Asia and Australia. It exceeds in compass the whole of the four continents taken together, and occupies more than a third part of the earth's area. On the west it borders on the Indian Ocean, on the north it communicates with the Arctic Ocean by Bering Strait, on the south it is bounded by the Antarctic Ocean and on the east it joins the Atlantic at Cape Horn. Within this enormous circumference it includes the numerous islands composing the groups of Australasia, Polynesia, Melanesia and Micronesia, the islands on the west coast of America and those on the east and south coasts of Asia. The Pacific Ocean is divided into—(1) the north Pacific, bounded on the south by the tropic of Cancer, and comprising in the north and west Bering Sea and the Sea of Okhotsk, the Japanese Sea, the East or North China Sea and the Yellow Sea, and in the east the Gulf of California; (2) the central Pacific, stretching between the tropics, and comprehending the greater part of the numerous and beautiful insular groups known by the collective name of Polynesia; and (3) the southern Pacific, or South Sea proper, extending from the tropic of Capricorn to the Antarctic Ocean, and not diversified by many islands. The Pacific Ocean receives most of its affluents from the Asiatic Continent, the principal rivers being the Amur, Hoang-ho and Yang-tse-kiang; while from South America, owing to the proximity of the Cordilleras to the coast, it receives no stream of any consequence, and from North America only the Yukon, Columbia and the Rio Colorado.

The islands of this ocean are so numerous that it is difficult to give an enumeration of them, even in groups. Commencing on the American coast south of the Strait of Magellan, and proceeding north, an uninterrupted chain lines the shores of Chile and terminates in the large island of Chiloe. Many islets occur along the stretch of coast farther northward, and at the equator, about 700 miles west from the mainland, is the interesting Galapagos group. Northward along the coasts of Mexico and the United States are the Revillagigedo, Alijos, Guadalupe and several other small groups, while lining the coasts of Canada and Alaska is a chain of large islands, including among others those of Vancouver and Queen Charlotte. Turning west the Kodiak Archipelago lies at some distance off the east coast of Alaska, and the still larger chain of the Aleutian Islands, curving southwest from the extremity of that peninsula and terminating the groups of the Pacific, so far as they belong to the American continent. On the opposite continent of Asia the islands commence with the Kurile chain, stretching southwest from the extremity of the Peninsula of Kamchatka and afterward continued in the same direction by the far more important islands of Japan, the Philippines and other large islands of the Indian Archipelago. In the south region of the Pacific, beyond the tropic of Capricorn, the islands are few in number, but include the important group of New Zealand. Between the tropics the principal groups are, north of the equator, the Hawaiian, Ladrone or Mariana and Caroline Islands; and south of the equator, the Marquesas, Low Archipelago, Society, Friendly,

Fiji, New Caledonia, New Hebrides and Solomon groups.

The bed of the Pacific is composed largely of red clay, with extensive sections of blue and coral muds, Globigerina, Radiolarian, Diatom and Pteropod oozes, and in the eastern portion and south of Australia and New Zealand is fairly regular, ranging from 1,000 to 2,000 fathoms in depth. In the north, northwest and the south, east of New Zealand, are extensive deeps, the Tuscarora deep east of Kamchatka, the Kurile Islands and Japan, having a depth greater than 4,000 fathoms, the Aldrich deep east of New Zealand, over 5,100 fathoms. Between Guam and Midway islands (q.v.) the United States telegraph ship *Nero* in 1900 sounded a depth of 5,269 fathoms. The Fiji, Ellice, Solomon and Tonga islands lie on a plateau southeast of New Guinea, and New Zealand is, as it were, a peninsula of this plateau. The slope of the Asiatic continental shelf is much less than that of America. The mean depth of the Pacific is about 2,300 fathoms. See OCEAN.

The general laws regulating winds, tides and currents suffer fewer modifications in the Pacific than in narrow seas. The tidal wave, commencing at the equator, diverges from it toward the poles and, proceeding with great velocity and without an obstruction, is scarcely perceptible among the central islands of the Pacific. Hence in the Low Archipelago, at Bow Island and Tahiti, the rise is only one foot and at the Sandwich Islands two feet. It is only when, by the proximity of a mainland diminishing the depth of the water, or by any similar cause the natural course of the wave is changed, or obstacles to its progress are interposed, that an accumulation takes place, and high tides are formed. In the Pacific, however, these never attain the maximum heights for which some parts of the Atlantic and Indian oceans are celebrated. In the solitary instance of Cook's Inlet, Alaska Territory, the rise is as high as 28 feet; but on all the west coast of America it is usually below 10 feet, and only in the Bay of Panama varies from 13 feet to 15 feet.

The prevailing winds of the Pacific, like those of other great seas, are divided into regular or trade winds and variables. The trade winds of the Pacific are not so regular in their limits as those of the Atlantic, and this irregularity extends over a much wider region in the case of the southeast trade wind than in the case of the northeast. The cause of this is the greater number of islands in the South Pacific Ocean, which, especially in the hot season, disturb the uniformity of atmospheric pressure by local condensations. The northeast trade wind remains the whole year through within the northern hemisphere. In the middle of summer (about July) the zone within which it blows extends from about the Mariana or Ladrone islands, in 146° east longitude, to near the coast of North America (Lower California), and its southern limit begins to the south of the islands mentioned, in about lat. 13° N., gradually descends toward the east to about 8° N., and then rapidly rises again to about 20° N., near long. 115° W. In winter (about January) this zone extends from Borneo and the Philippine Islands to the American coast; and its southern limit, beginning about the northeast of Borneo, keeps between 2° and 4°

N. latitude until about long. 170° W., when it gradually rises to about 10° N. lat., at about 100° W. long. The southeast trade wind, on the other hand, advances beyond the equator, both in summer and winter, still preserving its original direction; in summer (July) to about 7° or 8° N. lat., and in winter (January) to about 5° N. lat., at 160° W. long. In July the zone of this trade wind extends from New Guinea and Australia to the neighborhood of the South American coast; and its southern limit, beginning off the coast of Australia, about lat. 24° S., gradually rises to about lat. 16° S., at long. 130° W., and then sinks again to about lat. 24° S. off the coast of South America. In January, on the other hand, the western limit of the southeast trade wind is about long. 175° W.; and its southern limit, commencing there about the equator, sinks gradually till it touches the Marquesas Islands, and then more rapidly till it reaches about 33° S. lat. off the South American coast. In the region lying to the west of this zone, and stretching from New Guinea and the Solomon Islands southeastward, there are no regular winds. West winds, accompanied by rains, here alternate with calms. Sometimes also irregular warm, moist winds reach this region from the north, but the regular northeast trade wind never visits it. The zones of the two trade winds are separated by regions of calms and of light winds, the limits of which vary of course, with the varying limits of these zones. In the Chinese seas the terrible typhoon occasionally rages and may occur at any season of the year.

The following table exhibits the mean velocity of the currents of the Pacific Ocean in 24 hours:

SOUTH PACIFIC OCEAN.

Southern equatorial current.....	24 miles.
Cross current.....	20 "
Current of Cape Horn.....	18 "
Humboldt's current.....	15 "
Current of Mentor.....	16 "
General current of Australia.....	12 "
Periodical currents of Australia {	6 miles near the land. 16 miles at sea.

NORTH PACIFIC OCEAN.

Northern equatorial current.....	30 miles.
Equatorial counter current.....	15 "
Monsoon current of the Carolines.....	3 "
Japan current.....	31 "
Current of N. W. coast of America.....	16 "
Current of Kamchatka.....	8 "
Bering's current.....	14 "

The periodical current of the west coast of Mexico, occasioned by the monsoons of this coast, resembles them in its alternations. It extends from Cape Corrientes to the Cocos Islands, preserving a nearly uniform breadth of 350 miles. It was first noticed by Humboldt. See OCEAN CURRENTS.

The Portuguese were the first Europeans who entered the Pacific, which they did from the east. Balboa, in 1513, discovered it from the summit of the mountains which traverse the Isthmus of Darien. Magellan sailed across it from east to west in 1520-21. Drake, Tasman, Bering, Anson, Byron, Bougainville, Cook, Vancouver, Lapérouse and others traversed it in different directions in the 17th and 18th centuries. Consult Bancroft, H. H., 'New Pacific' (San Francisco 1912); Brigham, W. T., 'Index to the Islands of the Pacific' (Honolulu 1900); Burney, 'Chronological History of

Discoveries in the South Sea'; Enoch, C. R., 'Secret of the Pacific' (New York 1912); Flint, J. M., 'Contributions to the Oceanography of the Pacific' (Washington 1905); Fox, F., 'Problems of the Pacific' (Boston 1913); Colquhoun, 'Mastery of the Pacific'; Thomson and Murray, 'The Challenger Expedition' (1880-95).

PACING. See HORSE, TROTting and PACING.

PACINI, pa-chē'nē, **Filippo**, Italian anatomist: b. Pistoia, 1812; d. 1883. He was educated at Florence and at Pisa, and in due time was appointed to the chair of anatomy at the University of Florence. In 1835 Pacini rediscovered the peripheral nerve terminations described by Vater in 1730. He wrote extensively on anatomy, pathology and therapeutics. His most important work is one on artificial respiration, which described the methods employed by him in resuscitating new-born children.

PACINI, Giovanni, Italian composer: b. Catania, 1796; d. 1867. He studied under Marchesi and Furlanetto and in 1813 brought out his first operatic effort, 'Annetta e Lucindo.' By 1834 he had added 41 operas to his list and was the most successful composer in Italy in his time. He established a school of music at Viareggio and pupils from all over the world flocked thither to receive instruction. He again began to compose after 1840 and added about 50 more operas to his list, including 'Medea' (1843); 'Saffo' and 'La Regina di Cipro' (1846).

PACINIAN CORPUSCLES, or **PACINIAN BODIES** (also called corpuscles of Vater), elliptical concentrically striated bodies of cellular tissue, capillary vessels, a watery fluid, granular material and epithelioid cells; first described by Filippo Pacini in 1840. Into each corpuscle runs the axis-cylinder of a nerve (probably covered by the sheath of Schwann), terminating in a bulbous enlargement, or branching so that each nerve-fibril has a similar terminal knob. These corpuscles are the "peripheral end-organs" of certain sensory nerves and in the human being are found chiefly in the subcutaneous tissue of the palms of the hands and the soles of the feet, but have been found also in the genital organs, the nipples and other portions of the body. They are found in lizards, snakes, birds and mammals. They are tactile organs.

PACINOLO, **PACCIOLI**, or **PACIMOLO** (LUCAS DI BORGO), an Italian mathematician: b. Tuscany, c. 1450; d. c. 1510. He was a Franciscan monk and taught mathematics at Florence, Venice, Padua, Naples and Rome. His chief work, 'Summa de Arithmetica, Geometria, Proportionibus et Proportionalitate' (1494), is important as being the first treatise on mathematics ever printed, and as embodying the results of mathematical research up to that time. A treatise on bookkeeping (published 1495) is also attributed to Pacinolo. See FINGER NOTATION.

PACINOTTI, pä'chē-nōt'tē, **Antonio**, Italian physicist: b. Pisa, 1841; d. 1912. He received his education at the University of Pisa, where he was professor for two years. In 1864 he removed to Bologna and in 1873 to the University of Cagliari. After 1882 he was

again at Pisa. In 1860 he invented a dynamo with a special type of ring armature windings.

PACIUS, pä'sē-us, **Friedrich**, Finnish composer and violinist: b. Hamburg, Germany, 1809; d. 1891. His violin instruction was received from Spohr. In 1834 he settled in Helsingfors as teacher of music at the university. He is the author of the national songs 'Vartland,' 'Suomis Sang,' 'Soldatgossen'; the great operas, 'Kung Karls Jakt' and 'Lorelen' and the operetta, 'Prinsessan of Cyprien.' Pacius was one of the greatest performers of his time on the violin.

PACKARD, päk'ard, **Alpheus Spring**, American educator: b. 1798; d. 1884. He was educated at Bowdoin College; was tutor there in 1819-24 and from 1824 to 1865 held the professorship of Greek and Latin languages and literatures. In 1869 Dr. Packard was appointed Collins professor of natural and revealed religion and also librarian. In 1882-84 he was acting president of Bowdoin. With Cleaveland he wrote 'The History of Bowdoin College, with Biographical Sketches of its Graduates' (1882). He wrote many articles for periodicals and edited 'Xenophon's Memorabilia Socratis,' with English notes (1839; 3d ed., 1843) and 'Works of the Rev. Jesse Appleton, with a Memoir' (1836-37).

PACKARD, **Alpheus Spring**, American zoologist: b. Brunswick, Me., 19 Feb. 1839; d. Providence, R. I., 14 Feb. 1905. He was graduated from Bowdoin in 1861 and the Maine Medical School in 1864; and was for three years a special student under Agassiz at the Lawrence Scientific School, Harvard University. From 1865-66 he was librarian and custodian of the Boston Society of Natural History; and from 1867-78 curator, and then director, of the Peabody Academy of Science. In 1871-73 he was State entomologist of Massachusetts; from 1877-82 he was a member of the United States Entomological Commission, participating in several scientific expeditions under their charge. In 1878 he became professor of zoology and geology at Brown University. His most important contributions to science have related to the classification and anatomy of the arthropoda, especially insects; he proposed a new classification of insects, and regrouping of the phyla of the arthropoda. As an evolutionist he is one of the founders of the Neo-Lamarckian school, to which he gave that name. His writings include 'Guide to the Study of Insects' (1869); 'The Mammoth Cave and its Inhabitants,' with F. W. Putnam (1872); 'Our Common Insects' (1873); 'Life History of Animals' (1876); 'Half Hours with Insects' (1877); 'Injurious Insects of the West' (1877); 'Development and Anatomy of Limulus Polyphemus' (1885); 'Entomology for Beginners' (1888); 'Textbook of Entomology' (1898); 'Lamarck, the Founder of Evolution, his Life and Work' (1901). He was one of the founders and for 20 years editor-in-chief of the *American Naturalist*.

PACKARD, **John Hooker**, American physician: b. Philadelphia, 15 Aug. 1832; d. 20 May 1907. He was graduated from the University of Pennsylvania in 1850; was acting surgeon in the United States army (1861-65); and surgeon to the Episcopal Hospital, Phila-

delphia (1863-84). He was also surgeon to two other hospitals in his native city, the Pennsylvania (1884-96) and the Woman's (1876-77). He published 'Minor Surgery'; 'Lectures on Inflammation'; 'Operative Surgery,' etc.

PACKARD, Joseph, American Protestant Episcopal clergyman: b. Wiscasset, Me., 1812; d. 1902. In 1831 he was graduated at Bowdoin College, in 1834-36 taught at Bristol College, Pennsylvania, and entered the ministry in 1837. In 1836-90 he held the chair of sacred literature in the Protestant Episcopal Theological Seminary of Virginia. He was professor emeritus after 1890; in 1872-85 served on the committee for revision of the Bible and was dean of the seminary for 15 years. He wrote 'Questions on the Gospels' (1855); commentary on Malachi in Lange's 'Commentary' (1874) and contributions to ecclesiastical periodicals. Consult his autobiography, 'Recollections of a Long Life' (Washington 1902).

PACKARD, Lewis Richard, American classical scholar: b. Philadelphia, Pa., 1836; d. 1884. In 1856 he was graduated at Yale and made post-graduate studies at Berlin. He became assistant professor of Greek language and literature at Yale in 1863 and after three years was made full professor. Mr. Packard was elected president of the American Philological Association in 1880 and in 1883 was made second director of the American School of Classical Studies at Athens. He was joint editor of the 'College Series of Greek Authors' (1885 et seq.). Consult his 'Studies in Greek Thought' (a collection of essays, 1886).

PACKARD, Silas Saddler, American educator: b. Cummington, Mass., 28 April 1826; d. New York, 10 Oct. 1898. He was educated at the Granville Academy, Ohio, and engaged in teaching at 17. He originated an admirable system of commercial training and in 1858 organized with Bryant and Stratton a business college in New York, which later became the Packard Commercial School. He founded the *Niagara River Pilot* in 1853 and edited it until 1856, and in 1868-70 published *Packard's Monthly*. He was president of the congress of business education at the World's Fair in 1893, and author of numerous textbooks, among which are 'The Packard Manual of Bookkeeping and Correspondence'; and 'The Packard Arithmetic.'

PACKARD, William Alfred, American classical scholar, son of A. S. Packard (1798-1884) and brother of A. S. Packard (1839-1905): b. Brunswick, Me., 1830; d. 1909. He was graduated at Bowdoin College in 1851 and in 1857-58 studied at the University of Göttingen, Germany. Subsequently he was appointed to the chair of Latin language and literature at Princeton University. He was a frequent contributor to the *Princeton Review* and the *Presbyterian Review*. He published an improved translation of Curtius' 'Griechische Geschichte.'

PACKER, pāk'ēr, Asa, American capitalist: b. Groton, Conn., 20 Dec. 1806; d. Philadelphia, 17 May 1879. He worked at the trade of tanning, then as apprentice to a carpenter, went to Pennsylvania in 1822, and in 1823 took charge of a boat on the Lehigh Canal, and later connected himself with coal-mining and the transportation system between Pottsville, Pa., and

New York as a builder of locks and boats for the canal system. In 1844 he was a member of the Pennsylvania legislature. The Lehigh Valley Railroad was projected by him, and was completed from Mauch Chunk to Easton in 1855. As a Democrat he served two terms in Congress (1853-57). Out of the great wealth which he acquired he made many generous public gifts, the founding and endowment of Lehigh University (q.v.) being his most conspicuous benefaction.

PACKER COLLEGIATE INSTITUTE, a secondary school for girls, located in Brooklyn, N. Y. It was chartered in 1853 and opened to students in November 1854; it stands on the site of the building of Brooklyn Female Academy (founded 1845), which was burned in December 1852. The work of the institute is in three departments, elementary, academic and collegiate; the elementary work is in seven grades, the academic in four and the collegiate in two. Though the institute is a high school and confers no degrees, the work of the collegiate department overlaps the first two years of a regular college course.

PACKING INDUSTRY. See MEAT PACKING; MEATS AND MEAT PRODUCTION.

PACO, a name of the alpaca (q.v.).

PACTOLUS, pāk-tō'lūs, Asia Minor, the classic name for the modern SARABAT, a small Lydian stream anciently celebrated for its golden sand, the reputed source of the wealth of Cræsus. It is now comparatively worked out. It rises on the north side of Mount Tmolus, flows past Sardis, and has its outlet in the Hermus.

PACUVIUS, pa-kū'vi-ūs, Marcus, Roman tragic poet, nephew of the poet Ennius: b. Brundisium, about 220 B.C.; d. Tarentum, about 130 B.C. He was a student under Ennius and not only a poet but a painter as well, as is shown by the many allusions to his picture of Hercules in the Forum Boarium. Most of his tragedies followed Greek models; such were the 'Antiope' and the 'Dulorestes,' the latter being adapted from Euripides' 'Iphigenia in Tauris'; among native plays by him the one most often mentioned is the 'Paulus,' written in honor of Lucius Æmilius Paulus. He also wrote satires, but of this great body of work nothing but a few quotations by grammarians and rhetoricians has come down to us; these are edited by Ribbeck in 'Scænicæ Romanorum Poesis Fragmenta' (Leipzig 1897). Consult Müller, 'De Pacuvii Fabulis' (1890).

PADANG, pä-däng', Sumatra, two Dutch residences or provinces on the west coast of the island, known respectively as the Highlands and the Lowlands of Padang; also the capital city of the Lowlands of Padang at the confluence of the Padang Aran and the Padang Idel, which are very shallow and so make a poor harbor. The present port of Padang is Emmahaven, separated from Padang by a hill known as the Apenburg because of the apes there. The city has government workshops, barracks, schools, hospitals and churches, and was the earliest Dutch city in Sumatra (1666). It does business with the interior of the island by rail, and exports nutmegs, coffee, cinnamon, rattan, copra, tobacco, gum and hides. The

city has a European and a Chinese quarter, in which there are a few stone houses; elsewhere bamboo is used. The climate is hot and not very healthful. The city has several consulates. Pop. about 90,000. The capital of the Highlands of Padang is Fort de Kock. Pop. 2,290.

PADDINGTON, England, a metropolitan and parliamentary borough of London, immediately north of the city of Westminster. Area, 1,356 acres. Bayswater is a well-known residential district and was a favorite haunt of artists in the 18th century. The borough returns one member to Parliament. Pop. about 142,551. Consult Bates, 'The Playground of Paddington' (1902); Robins, 'Paddington, Past and Present' (1853).

PADDLE, a wooden implement with a wide, flat blade which is used without a fixed fulcrum in propelling and steering canoes and boats, the operator spooning the water toward him. In canoes a double-headed paddle is sometimes used, being dipped alternately on either side. The paddle is found as a substitute for the oar in many parts of the world.

PADDLE-FISH, **SPOON-BILL CAT**, or **SPADE-FISH**, a singular ganoid fish (*Polyodon spathula*) of the sturgeon tribe, *Chondrostei* (q.v.), which takes its name from the extraordinary spatulate prolongation of the nasal bones and upper jaws into a thin, spade-like, mud-digging instrument, measuring a third to a quarter of the total length of the fish. It abounds in the more sluggish parts of the rivers of the Mississippi Valley and of the Southern States, and occasionally reaches a length of more than six feet and 75 to 100 pounds in weight. In general form it resembles a sturgeon, but the skin is destitute of plates or scales, except on the upper lobe of the tail, and is a dull greenish mud-color in hue. The gill-apertures are of large size, and the gill-covers are prolonged backward nearly to the middle of the body. The mouth is large and provided with teeth in the young, but they disappear as the fish grows older.

The paddle-fishes "feed chiefly on mud and minute organisms contained, stirring it up with the spatulate snout." Their spawning habits are little known, but apparently the eggs are voided as soon as the water where each fish lives reaches a fair degree of warmth; at this time they ascend the streams and bayous, swimming near the surface, and are caught by means of seines. At other seasons they may be caught on set-lines. Formerly the flesh, which resembles that of the sturgeon, was eaten only by the southern negroes, but now it finds a sale in many local markets, and is frequently smoked and sold for sturgeon. The greenish black roe is also coming into demand for the making of caviar. Another closely related form (*Psephurus gladius*) lives in Chinese rivers, and the two species constitute the order *Selachostomi* family *Polyodontidae*, fossil remains of which are found in Wyoming as far back as the Eocene. Consult Jordan and Evermann, 'American Food and Game Fishes' (1902), and other authorities therein cited.

PADDOCK, pād'ók, **Algernon Sidney**, American lawyer and politician: b. Glens Falls, N. Y., 9 Nov. 1830; d. Beatrice, Neb., 17 Oct. 1897. He studied law, and removing to Nebraska in 1857 was admitted to the bar there

and became prominent in the political life of the Territory. In 1859 he was delegate to the Territorial Republican Convention, and in 1860 and 1864 to the National Republican Convention. In 1861 he was appointed secretary of the Territory, holding this position till 1867 when Nebraska was admitted to the Union, for a part of this time acting as governor. In 1868 he declined an appointment as governor of Wyoming Territory. In 1875 he was elected to the United States Senate and again in 1887, while between his two terms in the Senate he was for four years a member of the Utah Commission. While in the Senate he was a member of several important committees, including the committee on pensions, on public lands, on post offices and on public buildings, and during his last term was chairman of the committee on agriculture and forestry.

PADDY-BIRD, the name among English-speaking persons in the East for various birds frequenting rice fields, especially small white egrets of several kinds.

PADELLA (Italian, from Latin *patella*, a small flat dish), a shallow vessel used in illuminations. A number of them are partially filled with oil or grease, in the middle of which is placed a wick, and are then placed so as to bring out when lighted the outlines of a building or the slope of a rising ground. The idea originated in Italy.

PADEMELON, a small, naked-nosed kangaroo of the genus *Halmaturus*, specifically *H. thetidis*, of New South Wales. It inhabits brushy districts and with others of its race in Australia and Tasmania is hunted for the sake of its flesh and hide.

PADERBORN, pā'dēr-börn, Germany, a town and episcopal see in the Prussian province of Westphalia, at the sources of the Pader, 50 miles southeast of Münster. It is an old town, with narrow streets and antique houses. It has a fine recently restored cathedral, with a tall and massive tower which, as well as the crept, belongs to the 11th century—both in the Romanesque style; while the body of the church, 345 feet long, is of the 13th century. It has also a fine market place, an ancient town-house and several other ancient churches and chapels. The city was much favored by Charlemagne. Throughout the Middle Ages Paderborn, which was a Hansatown, was the seat of a bishop who was also a temporal prince. The bishopric was secularized in 1803 and was taken over by Prussia. The industries include printing, flour, soap, glass, beer and tobacco. The ground on which it stands teems with mineral springs. The university which existed at this place from 1614 was suppressed in 1819. Pop. about 27,000, mostly Roman Catholics.

PADEREWSKI, Ignaz Jan, pianist and composer; first premier of the Polish Republic: b. Kurilovka, Podolia, Poland, 6/18 Nov. 1860. He began studying music at the Warsaw Conservatorium under Raguski at the age of seven and went on his first concert tour in 1876-77, touring Russia, Siberia and Rumania. He became teacher of the pianoforte at his first academy in 1879 and three years later went to Berlin, studied under Urban and Wüerst and, finally, at Vienna under the distinguished teacher Leschetizky. In 1887 he made his for-

mal appearance as a concert pianist in Vienna and 1889 in Paris, from which time his career has been an ever-extending triumph, he being universally regarded as the most brilliant executant on the piano since Liszt. He gave a series of recitals in London during May 1890 and toured America in 1891, where he has frequently appeared since. By a deed of trust, 15 May 1900, he established the Paderewski Fund, to be held as a permanent trust for the purpose of aiding musical education in the United States, and particularly for the support and encouragement of American composers. Prizes are offered every three years for the best compositions submitted by American-born composers to a selected board of judges. The first competition was held in 1902, when three prizes of \$500 each were awarded: for a symphony, *The Seasons* (Henry K. Hadley); a composition for chorus, solos and orchestra, *A Star Song* (Horatio W. Parker); and a sextet for wind instruments (Arthur Bird). The exact terms of the trust provide (1) \$500 for the best orchestral composition in symphonic form; (2) \$300 for a composition for solo instrument with orchestra; (3) \$200 for a piece of chamber music. In the second competition, in 1906, only one award (\$500) was made, for an *Ouverture Joyeuse*, to Arthur Shepherd of Salt Lake City. M. Paderewski's first wife died young, leaving a son. He married, secondly, Mme. Gorski in 1899. Between 1913 and 1918 he appeared frequently in the United States, and during the war played an active part in the relief of Polish war sufferers and in the public propaganda to restore the independence of Poland. He became Premier on 17 Jan 1919, and in April of that year he presented the case of Poland to the Peace Conference in Paris.

PADILLA, pā-thēl'yā, **Juan Lopes de**, Spanish warrior: b. Toledo, about 1490; d. 24 April 1521. A the outbreak of the insurrection of the Castilian towns against the arbitrariness of Charles V, the Santa Junta entrusted him with the command of the forces of the comuneros. The Junta first tried to enthrone the insane queen Joanna. It offended the nobles, however, by its democracy, and replaced Padilla by the less competent Don Pedro de Giron. After several successes his force was defeated by the royal army at Villalar, 23 April 1521. He himself was wounded and taken prisoner and executed on the following day. The two letters in which, shortly before his execution, he took leave of the town of Toledo and of his wife Maria Pacheco, were known in Spain as models of magnanimous feeling and touching simplicity. Both he and his widow, who defended Toledo for some time after his death, until she was compelled to take refuge in Portugal, have become the subject of numerous dramas and poems.

PADILLA, Bolivia, capital city of the province of Tomina and department of Chuquisaca, 90 miles northeast of Potosi. Originally called Laguna, the city now bears the name of Manuel Asencio Padilla, a patriot of this province, killed at Villar, 14 Sept. 1816. Pop. about 1,700.

PADISHAH, in Persia, a title assumed by or applied to the shah, derived from *pati*, lord (protector) and *shah* (king, prince). It is also

applied to the sultan of Turkey and in India to the British sovereign.

PADMA, Hindu goddess of fortune and beauty, wife of Vishnu. See **SRI**.

PADUA, pād'ū-ā, or **PADOVA**, pā'dō-vā, Italy, a university city, capital of the province of the same name, 22 miles west of Venice, on the Bacchiglione. It is surrounded by a lofty wall flanked with bastions, and is entered by seven gates. It is connected by canals with the Adige and the lagoons of the Adriatic. The streets and squares are usually lined with colonnades. The largest and finest of the piazzas is the Piazza Vittorio Emanuele, formerly called the Prato della Valle, which is planted with trees, surrounded by a running stream and adorned with numerous statues of distinguished townsmen and other Italians. The principal buildings are the town-house or Palazzo della Ragione, an immense pile extending along the market place, erected between 1172 and 1219 and remodeled in 1420, standing upon open arches and containing a large hall adorned with fine mural paintings, about 400 in number; the late Renaissance Duomo or cathedral built in the 16th century, possessing a fine library, rich in rare books and manuscripts, and of which Petrarch, who was canon of the cathedral, is reckoned one of the founders; the baptistery of the cathedral, a fine Lombard building of the 12th century, its walls and cupola entirely covered with frescoes; and the Church of Saint Anthony. The most famous establishment in Padua is the university, one of the most ancient in Europe, said to have been founded early in the 13th century by Emperor Frederick II, but according to other accounts not founded till 1260, and sanctioned by Pope Urban IV in 1263. It was long renowned as the chief seat of law and medicine, and is celebrated for its long list of notable professors, including Galileo, Guglielmini and Fallopius, and for its students, including Dante, Petrarch and Tasso. The average annual attendance of students is 1,500. In connection with the university is a botanic garden, the oldest in Europe, containing some of the earliest specimens of trees and plants once rare, but now generally diffused; a library of over 200,000 volumes and an observatory. The manufactures include silk fabrics, ribbons, catgut, chemicals, machinery, automobiles, etc., and like the trade in cereals, oils, wines and cattle, are increasing. Padua is the see of a bishop and the seat of several superior courts and public offices. It claims to have been founded shortly after the destruction of Troy by the Trojan Antenor. Under the Romans it became a flourishing municipal town, but on the decline of the empire was sacked first by Alaric and then by Attila. Its great modern restorer was Charlemagne, under whose successors it successfully asserted its independence. In 1318 it fell under the domination of the Carrara family, and in 1405 under that of Venice, whose fortunes it has since followed. Among the distinguished men to whom Padua has given birth are the historian Livy, Sperone Speroni, a writer of tragedies in the 16th century; Mantegna; the poet Cesarotti. Pop. of city 50,000, with communal suburbs 96,250.

PADUCAH, pā-dū'ka, Ky., city, county-seat of McCracken County; at the confluence of the Tennessee and Ohio rivers, and on the

Nashville, Chattanooga and Saint Louis, the Illinois Central and the Chicago, Burlington and Quincy railroads, about 35 miles in direct line east by north of Cairo, Ill., and 80 miles southwest of Evansville, Ind. A splendid modern railway bridge which cost \$4,500,000 spans the river here. There is steamer connection with Mississippi, Ohio and Tennessee river ports. It was settled in 1821 by James and William Pore, and was incorporated 11 Jan. 1830. During the Civil War the city was occupied by General Grant in September 1861. It is in a productive agricultural region; in the vicinity are forests of hard and soft wood and deposits of fire-clay, glass sand, zinc and fluorspar; limonite is found within 30 miles, and coal, in rich veins, within 60 miles. It has extensive manufacturing interests; the chief manufactures are pig iron, lumber, veneering, building material, spokes, rims, staves, headings, barrels, curtain poles, furniture, stoneware, pottery, saddles, collars, harnesses, tobacco products, knit goods, canned goods, brooms, brick, proprietary medicines, boxes and flour. It has a large ore milling plant and novelty works, in all 91 manufactories giving employment to about 3,000 persons and the two railroads employ about 1,200. There is an extensive wholesale trade in clothing and food products, and in its own manufactures. The prominent public buildings are the United States government building, municipal buildings, churches and schools, Carnegie library. The educational institutions are Saint Mary's Academy, a high school, public and parish schools and a number of private schools. There are 23 churches. The six banks have a combined capital of \$1,350,000; the bank clearings are annually about \$50,000,000. The government is administered under a commission form of government with mayor and four commissioners. The city owns and operates the electric light plant. Pop. (1920) 24,735.

PÆAN, a word originally meaning "helper" or "healer." Homer applied it to the physician of the gods on Olympus. The title was later transferred to Apollo, and was used in hymns as his epithet. By a second transference, the hymn itself became called a pæan, and later similar invocations to the other gods came to be known by that name. Pæans were sung to ward off evil, as before a battle, on the march or when a fleet sailed out of harbor. They were also sung after a battle in token of gratefulness to Apollo. Pæans were also sung at public funerals and at banquets. Pindar and Bacchylides were among the more noted authors of pæans. Consult Fairbanks, A., 'A Study of the Greek Pæan' (New York 1900).

PÆDOGENESIS, the reproduction of animals while in the immature or larval stage. Thus certain salamanders (*Amblystoma*) produce eggs which develop into adults when the parents still retain the gills and are aquatic in their habits. (See AXOLOTL.) More strictly pædogenesis is applied to parthenogenesis (q.v.) in the larval stage. Best known instances are certain flies (*Musca*), where the larvæ produce eggs which develop without fertilization, inside the body and these finally escape by eating their way out, the parent being destroyed as a consequence.

PÆONIUS, Greek sculptor of the 5th century B.C.; b. Mende, Thrace. He is best known

through his statue of Victory erected at Olympia about 420 B.C., in commemoration of some battle, probably Sphacteria. The pedestal was triangular and about 30 feet in height. The figure of Nike is represented in flight, with feet barely touching the pedestal, the weight of the figure being supported mainly by the draperies. Other figures at Olympia were ascribed to Pæonius. Consult Gardner, E. A., 'A Handbook of Greek Sculpture' (London 1911).

PÆONY, a genus (*Pæonia*) of the order *Ranunculacææ*. With one exception (*P. brownii*), native to the Pacific Coast, the species are natives of Europe and Asia, and improved varieties and hybrids of the original wild sorts are found in most gardens, being valued for their hardiness, easy cultivation and large, attractive flowers. They are of two distinct groups: the herbaceous and the shrubby. The former group is the larger; they are perennials with tuberous rootstocks, large pinnate leaves and flowers ranging through all shades of red to white and yellow, the varieties cultivated being mostly the double forms. The plants will grow in almost any soil, but thrive best in rich, rather moist deep loam. The crowns should be set two inches below the surface and the ground, especially close to the plant, kept free from weeds. All weakly stems should be removed. When once established, annual dressings of stable manure should be given and the plants left undisturbed. Properly treated, pæonies will often prove satisfactory for 25 years without removal or renewal. *P. officinalis*, a native of southern Europe, produces large flowers abundantly during late spring. *P. albiflora*, a native of Siberia, blossoming about a month later than the preceding species, has fragrant flowers. Most of the cultivated varieties have been developed from these two species by Japanese and Chinese gardeners who have been cultivating and crossing them for centuries. The roots of *P. albiflora* are used by the Tartars for food. Several species are known as Chinese pæonies, but this term is more widely applied to hybrids and varieties of a more extended list than to the native Chinese kinds. They are fragrant and double-flowered. *P. tenuifolia*, or the "fern-leaved" pæony, is a native of Russia. Its blooms are single. The tree-pæony (*P. moutan*) often grows six feet tall, is much branched, and prolific of blooms ranging up to 12 inches across. It is somewhat less hardy than the common pæony, and in the North is often grown as a greenhouse plant. It is a native of China, where it has long been cultivated and where there are hundreds of varieties. In America it is less known than the first two species. When grown out of doors the tree-pæonies should be mulched with litter or leaves if in exposed places, especially north of Philadelphia. Pæonies are propagated by division of the root clusters, in the case of the herbaceous forms, and by cuttings of the young wood, or by layering, with the tree forms. The latter are also multiplied by grafting in early spring under glass upon the tubers of the herbaceous sorts. New varieties are produced from seeds obtained from the single flowers by fertilizing them with pollen from the double flowers. These seeds are sown in September: some ger-

minate the following spring, others not till a year later. Only a very few seedlings among thousands prove worthy of perpetuation. Consult Harding, A., 'The Book of the Pæony' (Philadelphia 1917).

PAER, pā-ār', **Ferdinando**, Italian composer: b. Parma, Italy, 1 June 1771; d. Paris, France, 3 May 1839. He was educated in Venice, summoned to the court of Vienna in 1795, and in 1801-07 was chapel-master at Dresden. After the battle of Jena he was attached to Napoleon's court, where he was imperial composer; in 1812-27 he directed the Italian grand opera at Paris, and in 1831 was elected to the Academy. He had received the cross of the Legion of Honor in 1828. His work is rich in melody and his greatness as an Italian composer is unquestioned, yet of his voluminous work little is remembered. He was at one time joint conductor with Rossini at the Théâtre Italean. His best known operas are 'Griselda' (1796); 'Camilla' (1801); 'Agnese' (1819).

PAESE DI CUCCAGNA, IL, ('The Land of Cockaigne'), obviously influenced by the French naturalistic school of writers, in particular by Zola. Matilde Serao in her massive canvas, 'Il paese di cuccagna' (1891), has described the destructive blight of the state lottery on all classes of Neapolitan society. Endowed with the quick eye of the born journalist, which sees and notes the varied phases of the teeming life of a great city, this energetic and gifted novelist has caught with her usual felicity the every expression of the multitude of gamblers, from the bootblack and little seamstress who risk their meagre sustenance, to the impoverished nobleman who seeks to retrieve the fallen fortune of his house.

The book unfolds like a great panorama in a series of episodes which portray the various strata of society madly bent on pursuing the mirage of suddenly acquired affluence, 'The Land of Cockaigne.' The author excels especially in her street scenes, in the study of crowds in action, in the multicolored hurly-burly of the Neapolitan population. Particularly fine is the opening scene of the lottery drawing with its intensified suspense, its paroxysm of excitement, and the utter dejection of the disappointed players. The description of the procession and miracle of San Gennaro, incomparable in its portrayal of the ecstatic religious fervor and gross superstition of the assembled worshippers, can well bear comparison to the procession in D'Annunzio's 'Triumph of Death' and the famous pilgrimage in Zola's 'Lourdes.' The minor characters, especially those low in the social scale, are drawn by a master hand.

The style, at times too insistent on elaboration of detail, pulsates with the life of Naples and reflects the speech of its people as only Serao can convey it. While not as perfect a work as the author's admirable sketches of Neapolitan life, episodic in treatment and over-enthusiastic on the thesis, 'Il paese di cuccagna' is Matilde Serao's most famous novel and a vivid, intense agonizing picture of a great evil. Consult Benedetto Croce, 'La letteratura della nuova Italia' (Bari 1915, v. 3); René Doumic, 'Un roman de moeurs napolitaines' in *La Revue des Deux Mondes* (July 1898); *The Atlantic Monthly*, 'Serao's Il paese di cuccagna' (August 1892); Henry, James, 'Notes on novel-

ists' (New York 1914). For an English translation consult 'The Land of Cockayne' (New York 1901).

ALFRED G. PANARONI.

PÆSTUM, pēs'tūm, ancient Greek city of Southern Italy on the west coast of Lucania and the present Gulf of Salerno (in ancient times *Sinus Puestanus*). It was founded as early as the beginning of the 6th century B.C. by colonists from Sybaris under the name of Posidonia (that is, "sacred to Poseidon" or Neptune), and attained great prosperity in the next century and a half. The city was conquered by the Samnites of Lucania, about 400 B.C., who probably Italianized its name into Pæstum. It did not regain its old position even when a century later (273) it became a Roman colony, but is famed in Roman poetry for its roses. It was sacked in the 9th century by the victorious Saracens, and in the 11th by Robert Guiscard. The poor village of Pesto, a railway station, now occupies the site, which has, however, two remarkable Doric temples, one to Poseidon, the tutelar god, and one to Demeter. Consult Labrousse, 'Les temples de Pæstum' (1877).

PÆTUS, pē'tūs, **Cæcinna**. See **ARRIA**.

PAEZ, pā'āth, a South American Indian tribe, supposed to constitute a separate linguistic stock. The tribe inhabits about a score of villages in the Central Cordilleras, to the west of Bogotá, Colombia. They live by hunting and wear little raiment despite the cold region in which they dwell. They weave hats, mats, rugs and cloth from magney fibre, and are also familiar with the working of gold. A house in which either a birth or death occurs is at once committed to the flames. The tribe numbers about 2,000 individuals. Consult Brinton, D. G., 'The American Race' (New York 1891).

PAEZ, José Antonio, Venezuelan patriot and soldier: b. Araure, 13 June 1790; d. New York, 6 May 1873. He was of native stock and with a body of llaneros, trained like himself as herdsmen, about 1810 joined the patriot army, in which he became division commander in 1819. He administered a severe defeat to the Spaniards in 1821 and in 1823 captured their last port, Puerto Caballo. Jealous of his successor in 1826 he attempted rebellion but was conciliated by Bolivar, who made him military and civil chief of Venezuela, thus paving the way for the war of Venezuelan independence in which Paez was the prime mover. In 1831-35 he was President of the new republic, and held the same office 1839-43 after acting as commander-in-chief during Vargas' administration and putting down two serious rebellions. In 1846 he was appointed dictator during the race war; in 1848 refused the presidency; later headed a rebellion against Monagas, but was defeated and imprisoned for several months; spent eight years in banishment; returned to Venezuela in 1858; was minister to the United States in 1860; became commander of the army in 1861; and was again driven into exile in 1863 by a revolution against his lieutenants, to whom he had entrusted large powers. The Federalist party was successful and Paez, leader of the Centralists, passed the remainder of his life in New York. Consult his 'Autobiografia' (1867),

PAGAN, pā-gān', India, a town of Upper Burma, on the east bank of the Irawady, 90 miles southwest of Mandalay. Pagan was founded in 847 A.D., and was the capital of Burma until 1298, when it was abandoned during a Chinese invasion. The remains of Buddhist temples and pagodas cover an extensive area, and are of great archaeological interest. Some of them are still occupied by priests, and the town has a population of about 6,000, chiefly Buddhists.

PAGANINI, pā-gā-nē'nē, **Niccolo**, Italian violinist: b. Genoa, 18 Feb. 1784; d. Nice, 17 May 1840. His father discerning the talents of his son put him at an early age under the best masters to learn the violin, and his public appearances began at the age of nine. In his 12th year he went to Parma, where he was taught counterpoint by Rolla (see **ROLLA**, **ALESSANDRO**) and Ghiretti. In 1797 he performed in the cities of Lombardy and afterward in the principal cities of all of Italy. He settled at Lucca, in 1805, where he was appointed principal violinist to the court chapel. In 1808 he left Lucca, and for five years lived an obscure and rambling life in Italy. In 1813 he reappeared before the world, and performed at Milan. He remained in Italy till 1828, suddenly appearing, and, after exciting unbounded enthusiasm by his public performances, as suddenly departing. In the year mentioned he visited Austria and Germany, appearing first in Vienna. The wonder which he excited was caused not merely by his extraordinary skill, but also the extraordinary stories circulated concerning his career and by his personal appearance, which had something weird and even demoniacal in it. His imitation of the flageolet, and his rendering of whole pieces on the G string were feats of astounding technique. The emperor of Austria appointed him his chamber virtuoso, and the king of Prussia his director of music. After visiting the great towns of Germany he proceeded to France and Great Britain. In Paris he produced an unprecedented sensation, and, as in Germany, made immense gains. While in England his profits amounted to \$85,000. He returned in 1834 to Parma, where he purchased the villa Gajona. Among his many compositions, one of the most celebrated is the 'Carnival of Venice.' Consult Kapp, J., 'Paganini' (Berlin 1913); Stratton, S. S., 'Niccolo Paganini; His Life and Work' (New York 1907).

PAGANS (Lat. *pagani*, those who live in the villages, *pagus*), those who remained unconverted to Christianity and the worship of the true God. While the cities were the centres of Christian life the remote villages (*pagi*) were still in pagan darkness, and their inhabitants kept up the practice of idolatry and the creed of polytheism. The men of the village, pagans, among the Latin races corresponded to the men of the heath, heathens, among the Teutonic races. The explanation has also been given that the pagans or "rustics" were so termed in contrast to the "soldiers of Christ." The term pagan, though formerly with the cognate "paganim" applied to Moslems, is not properly applied to Jews or Mohammedans since these worship the one God, the Jehovah, of Christians and Jews. The Mohammedan term *kafir*, meaning "unbeliever," is likewise withheld from Jews and Christians. The Jewish analogue of

"pagan" is *goy*, translated "gentile" (q.v.) meaning, "one who belongs to the nations" (of Greece and Rome)."

PAGE, Carroll Smalley, American legislator: b. Westfield, Vt., 10 Jan. 1843. He was educated at the People's Academy, Morrisville, Vt., and at Lamville Central Academy, Hyde Park, Vt. For many years he was a dealer in raw calfskins and acquired interests in various banking, manufacturing and other enterprises. In 1869-72 he was member of the Vermont house of representatives, in 1874-76 of the senate, and from 1872 to 1890 was member of the Republican State Committee. He was delegate to the Republican National Conventions of 1880 and 1912; was register of probate in 1880-91; savings bank examiner in 1884-88, and governor of Vermont in 1890-92. On 21 Oct. 1908 Mr. Page was elected to the United States Senate for the unexpired term (1908-11) of Redfield Proctor, deceased. He was re-elected for the terms 1911-17 and 1917-23.

PAGE, Curtis Hidden, American educator and editor: b. Greenwood, Mo., 4 April 1870. In 1890 he was graduated at Harvard University, after which he studied at Paris and at Florence. He was instructor in French and lecturer on English literature at Western Reserve University in 1891-92; instructor in French at Harvard in 1893-94; lecturer and tutor 1895-1906; adjunct professor 1906-08; professor of Romance languages and literatures 1908-09 at Columbia; professor of English literature at Northwestern University 1909-11 and since 1911 Winkley professor of English language and literature at Dartmouth College. In 1905 he was associate editor of *Poet Lore* and of the *Pathfinder* the following year. Professor Page has translated 'A Voyage to the Moon,' by Cyrano de Bergerac (1899); 'Songs and Sonnets of Ronsard' (1903); 'The Best Plays of Molière' (2 vols., 1907); 'Tartuffe' (1909); 'The Man who Married a Dumb Wife,' by Anatole France (1915). He is a contributor of poems, essays and stories to leading magazines and has edited 'British Poets of the Nineteenth Century' (1904); 'Rabelais' (1905); 'The Chief American Poets' (1905); 'Golden Treasury of American Songs and Lyrics' (1914).

PAGE, David Perkins, American educator: b. Epping, N. H., 1810; d. 1848. He received his education at Hampton Academy and for several years was principal of the High School at Newburyport. From 1845 to 1848 he was principal of the Albany State Normal School. He published 'Theory and Practice of Teaching, or the Motives of Good School Keeping' (1847), a work of permanent value to educators. Consult the edition of 1886 in which there is a short biography of the author by W. H. Payne.

PAGE, John, American legislator: b. Rosewell, Va., 17 April 1744; d. Richmond, Va., 11 Oct. 1808. He was graduated from William and Mary College in 1763, where he was intimate with Thomas Jefferson. He served under Washington in an expedition against the French and Indians, and during the American Revolution acted as a member of the committee of public safety and as lieutenant-governor of the commonwealth, sacrificing to the cause of the colonies a large share of his private fortune. He served in Congress in 1789-97, and in 1802

was elected governor of Virginia. In 1805 he was appointed by President Jefferson commissioner of loans for Virginia, which position he held until his death.

PAGE, Richard Lucian, naval officer, soldier: b. Clarke County, Va., in 1807; d. Norfolk, Va., 1901. Page entered the United States navy as midshipman in 1824 and in 1855 he reached the grade of commander. During this period his service was the usual routine of sea and shore duty. At the outbreak of the War of Secession he resigned and entered the Confederate service as commander in the navy. He fortified the mouth of the James River and other points on the coast, and then established large ordnance foundries at Charlotte, N. C., which he managed for two years. In 1864 he was made brigadier-general and placed in command of the outer defenses of Mobile Bay. His defense of the forts against Farragut's bombardment was a magnificent exhibition of courage and endurance. After the war General Page resided in Norfolk where he was for several years superintendent of schools.

PAGE, Thomas Jefferson, American naval officer, grandson of John Page (q.v.): b. Shelly, Gloucester County, Va., 4 Jan. 1808; d. Rome, Italy, 26 Oct. 1899. In 1853-56 he was lieutenant-commander in explorations of the La Plata region in South America, and in February 1855 his vessel was fired upon from a Paraguayan fort. Resigning in 1861 he then entered the Confederate service, was commissioned commodore and in 1862 was sent to England to take charge of a cruiser. As, however, he was prevented from taking the ship out he secured the command of a small iron-clad at Copenhagen, which was soon after seized from him while in a Spanish port. Leaving the service he subsequently resided in Argentina and in Florence, Italy. He wrote 'La Plata, the Argentine Confederation, and Paraguay' (1859).

PAGE, Thomas Nelson, American lawyer and author: b. Hanover County, Va., 23 April 1853; d. there, 1 Nov. 1922. Educated at Washington and Lee University, studied law at the University of Virginia, was admitted to the bar, and established himself in practice at Richmond. His avocations became literature and lecturing. Perhaps no post-bellum writer has depicted with so rare a skill the negro and white life of slavery, war-time and reconstruction. His rendering of the Virginia colored dialect in such stories as 'Marse Chan,' first printed in the *Century* (1884); later in the collection 'In Old Virginia' (1887), assumed a real philological importance. Among his further writings are 'Befo' de War,' poems by A. C. Gordon (1888); 'On Newfoundland River' (1891); 'Elsket' (1891); 'The Old South,' essays (1892); 'Red Rock' (1898); 'Gordon Keith' (1903); 'Bred in the Bone' (1904); 'The Negro' (1904); 'The Old Dominion' (1908); 'Robert E. Lee' (1911); 'The Land of the Spirit' (1913); 'The Stranger's Pew' (1914). In 1913 he was appointed by President Wilson as Ambassador to Italy. He is a member of the American Academy of Arts and Letters. See IN OLE VIRGINIA.

PAGE, Walter Hines, American publisher: and diplomat: b. Cary, N. C., 15 Aug. 1855; d. Pinehurst, N. C., 21 Dec. 1918. He was educated at Randolph-Macon College, Va., and

Johns Hopkins University, abandoned teaching for literary work and became editor of *The Forum* 1890-95, literary adviser to Houghton, Mifflin and Company, publishers, 1895-99; and editor of *The Atlantic Monthly* 1896-99. He was one of the founders of the publishing house of Doubleday, Page and Company in 1899; the editor of *World's Work* from 1900 to 1913, and from 1913 to 1918 during the arduous period of the Great World War was American Ambassador to Great Britain. He received the degree of D.C.L. from Oxford University in 1914. He was the author of numerous magazine contributions and of 'The Rebuilding of Old Commonwealths' (1902).

PAGE, William, American artist: b. Albany, N. Y., 23 Jan. 1811; d. Tottenville, Staten Island, 1 Oct. 1885. He studied under James Herring and Samuel F. B. Morse, at the Academy of Design, and lived 11 years in Italy, copying the Italian masters and especially Titian. He spent much time in analyzing the methods of that master and was so successful in imitating his style and coloring that one of his pictures was seized by the Florentine authorities as an original Titian which was being conveyed out of the country. In 1836 he was elected a member of the National Academy, of which he was president, 1871-73. Among the portraits painted by him are those of John Quincy Adams, the Brownings, Charlotte Cushman and others, including a full-length likeness of Admiral Farragut, which was purchased and presented to the emperor of Russia. His chief paintings are 'The Holy Family' (1837); 'The Last Interview' (1838); 'Ruth and Naomi' (1880).

PAGEANT, paj-ənt. The exact derivation of this word is uncertain. The pageant in the old-world sense was originally a spectacular street procession, with more or less symbolical figures and tableaux mounted on movable platforms or trolleys. Most of the early references are contained in Sharp, T., 'Dissertation on the Pageants or Dramatic Mysteries, anciently performed at Coventry' (Coventry 1825). Observe that in this title the pageant is very properly bracketed with the mystery, for nothing can be more certain than that it developed hand in hand with the mediæval mystery play. With the abatement of superstition that followed the passage of the year 1000 A.D., when so many gloomy prophecies went for nought, the people took heart of grace and called for entertainment; and if they might make merry in the field and in the shop, why not also in the church? Hence the ecclesiastical play, and the steady growth of the community folk play, under many secular forms, up to the advent of the Elizabethan dramatists in England, and of Corneille in France. The earliest recorded pageant in England was in 1236, on the occasion of a royal marriage at Canterbury. Pageantry was for a long time an important adjunct to coronation festivities, and was extremely popular with the people. In the 15th century a king of England granted a parcel of land and the money with which to build a pageant house to the Company of Weavers. Not the least of the services of this guild was that while they wove the most beautiful of English tapestries they also carried the joys of pageantry to the highest pitch of those days. In the following century the pageant festival at Kenilworth Castle

in honor of Queen Elizabeth created a tradition of splendor. The lord mayor's show in London, and the parades of labor and other fraternities, with their banners and tableaux, are but lean and limp survivals of the old pageants. Even to this day many of the cities of Great Britain, France, Holland, Belgium, Germany, Italy, etc., commemorate their great men and the proud events of their history by processional pageants of the citizens in the costumes of many periods.

In the United States the celebrations of *Mardi Gras* in New Orleans and elsewhere in the South, the Festival of the Veiled Prophet in Saint Louis and other harvest festivals, the flower festivals of Southern California, with that of La Portola in San Francisco, are all direct descendants of the older forms of pageantry. In 1863, at Saint Louis, an early form of indoor war pageant was presented in a series of historic tableaux entitled "America as it was, and America as it is." But the pageant in its late development is usually a far cry from these simple parades and spectacles. Episodic and dramatic construction, historical in content, educational and social as well as æsthetic in its aim, the writers, composers, designers and all other artists implicated, have nowadays a scope for creative energy that was quite beyond the compass of the old régime. (See COMMUNITY DRAMA). With the two already mentioned types in point of structure (the parade and the dramatic) it should be observed that there are also two main types in respect to content: (a) the social, concerning itself with some didactic phase, as illustrated by the Educational, the Renaissance and the Perfect City pageants; (b) the historical, envisaging the development of a given community, as shown in the Deerfield, Westchester, Peterborough, Illinois, Cape Cod and Indiana pageants. The historical pageant has been described by William Chauncy Langdon as "drama in which the place is the hero and the development of the community is the plot. . . . The modern pageant is an instinctive expression in dramatic form of the new community spirit; and as there never before was such a community spirit in the history of the world, so there never was such an expression of it. . . . Folk-play would be a more technically correct expression." The same writer, Mr. Langdon, in reviewing the fact that the technique of the historical pageant has reached a remarkably high standard in the United States, expresses himself conservatively in the following words: "In variety of form, in the pageant use of symbolism, in music, color, dance, in the crystallization of the civic value of the pageant—in these respects I believe we may fairly claim that the American pageant has made some advance upon the English." Educational centres have turned to the pageant form, not only for the furtherance of their immediate pedagogical ends, but also for drawing the attention of elders to the educational system, persuading them to co-operation and to the unifying of the whole community life. The pageant spirit primarily seeks to encourage people of all classes and ages belonging to the institution or locality promoting the occasion to involve themselves in democratic and festal fashion in the preparations and performances. The list of the most important of recent pageants, with the names of the pageant authors, is as follows:

ENGLISH PAGEANTS.

1905. The Sherborne Pageant. (L. N. Parker).
1906. The Warwick Pageant. (L. N. Parker).
1907. The Saint Edmundsbury Pageant. (L. N. Parker).
- The Liverpool Pageant—a procession. (D'Arcy de Ferrara).
- The Oxford Historical Pageant. (Frank Lascelles).
- The Portchester Pageant.
- Romsey Millenary Pageant. (F. R. Benson).
- The Saint Albans Pageant. (H. Jarman and P. Carr).
1908. The Chelsea Historical Pageant. (J. Harry Irvine).
- The Dover Pageant. (L. N. Parker).
- Winchester National Pageant. (F. R. Benson).
- Gloucester Historical Pageant. (G. P. Hawtrej).
- The Quebec * (North America) Tercentenary Celebration. (P. Lascelles).
1909. The Colchester Pageant. (L. N. Parker).
- The Bath Historical Pageant. (E. Baring).
- The English Church Pageant. (Hugh Moss).
- Stepney Children's Pageant at London. (L. N. Parker and F. J. H. Darton).
- The National Pageant of Wales at Cardiff. G. P. Hawtrej).
- The York Pageant. (L. N. Parker).
1910. The Army Pageant at London. (F. R. Benson).
- The Chester Historical Pageant. (G. P. Hawtrej).
- The Ilford Children's Pageant. (L. C. F. Robson).
- The Pageant of South Africa at Cape Town. (P. Lascelles).
1911. The Pageant of London. (P. Lascelles).
- The West Dorset Historical Pageant at Bradpole. (E. Lloyd).
- Mid-Gloucestershire Historical Pageant of Progress. (Miss May E. Cull).
1912. Oxford Millenary Pageant.

*British in form, in spirit and subject matter and therefore included in this list.

PAGEANTS IN THE UNITED STATES.

1908. Pageant of Education, Boston, Mass. (Lotta A. Clark and Mrs. Cyrus A. Dallin).
- Founders' Week Pageant-Parade, Philadelphia, Pa. (One of the best modeled parades ever held in America: In form it approached the pageant. (Ellis P. Oberholtzer).
1909. Pageant of the Italian Renaissance, Chicago, Ill. One of the finest pieces of pageant writing accomplished in America or England. (Thomas Wood Stevens).
- Bronxville Pageant of Westchester County, N. Y. The first and one of the most complete American pageants of the historical type. (Violet Oakley and Eugene Sanger).
- Lake Champlain Tercentenary Indian Pageant. Exclusively Indian; performed by members of an Indian Tribe. (L. O. Armstrong).
- Pageant of Illinois, Evanston, Ill. White Man's civilization, and destruction of Indian tribal life of the West. (Thomas Wood Stevens).
- Hudson-Fulton Celebration. Consult Hall, E. H., "Fulton-Hudson Celebration, 1909;" Albany 1911).
1910. Ripon Historical Pageant, Ripon, Wis. By the faculty and students of Ripon College. (J. F. Taintor).
- Pageant of Old Deerfield, Deerfield, Mass. (Margaret M. Eager).
- MacDowell Memorial Pageant, Peterboro, N. H. (George P. Baker and Mrs. Edward MacDowell).
- Pageant of the Perfect City, Boston, Mass. The Boston civic pageant of 1915, also. Presented the development of the home. There were 2,000 participants including a tribe of Iroquois Indians. (Lotta A. Clark).
1911. Pageant of the History of Minnesota, Saint Paul, Minn. (L. W. Ziegler and Lilly A. Long).
- Pageant for Independence Day, Chicago, Ill. Shows growth of the idea of freedom. (T. W. Steven and K. S. Goodman).
- Pageant of Thetford, Vt. The first of a series on the "New Country Life." (William Chauncy Langdon).
1912. Historical Pageant, Schenectady, N. Y. (Constance D. Mackay).
- Historical Pageant, Philadelphia, Pa. One of the largest and most important of pageants. Realistic. Over, 6,000 participants. (Ellis P. Oberholtzer).
- Y. W. C. A. Foreign Pageant (Composed by a committee of which Miss H. L. Boutelle was chairman. Given simultaneously in some 75 different cities during the "World's Week of Prayer").
- Pageant of Saint Johnsbury, Vermont. (W. C. Langdon).

1913. Pageant of the Old South Church, Boston, Mass. Indoors. (J. L. Smith and H. C. Greene).
Irish Pageant at New York. Indoors. (Anne Throop Craig).
Wisconsin Pageant, University of Wisconsin. (T. W. Stevens).
Pageant of Meriden, N. H. Education in the New Country Life. Music by Arthur Farwell. (Lotta A. Clark).
Pageant of Darien, Conn. Pageant of the Commuter. Music by Arthur Farwell. (W. C. Langdon).
1914. Progress of Women. Presented by the Men's League for Woman Suffrage, in the 69th Street Armory, New York. (Hazel Mackaye).
Romance of Work. Presented by the Association of Working Women in the 69th Street Armory, New York. (Mary P. Beegle).
"The Padres" and "The Pathfinder." Pageant-dramas presented at Santa Cruz, Cal. (Perry Newberry).
The Pageant of Nevada History, Reno, Nevada. (Jeanne E. Wier).
Pageant of Cape Cod, Bourne, Mass. Celebrated the completion of the Cape Cod Canal. Music by Daniel Gregory Mason. (W. C. Langdon).
1914. Pageant of St. Louis. Presented with the "Masque of Saint Louis," by Percy Mackaye. One of the most renowned of all pageants. (T. W. Stevens).
Pageant of the Champlain Valley, Plattsburgh, N. Y. (Margaret M. Eager).
Pageant of Chicago, Ravinia, Ill. (Ruth Coffin Collins).
Roger Bacon Pageant, Columbia University, New York. (John Erskine).
Historical Pageant of Georgia, Atlanta, Ga. Given indoors by the D. A. R. (Mrs. W. L. Peel).
1915. Pageant of Austin, Texas. Music by Frank LeFevre Reed. (W. C. Langdon).
Brooklyn Historical Pageant, New York. (Virginia Tanner).
Pageant and Masque "The Golden Legend of California." Presented at the Exposition Park, Los Angeles, Cal. (Alfred Allen).
1916. Pageant of Indiana, Indianapolis, Ind. Shows the drama of the development of the State as a community from its exploration by La Salle to the centennial of its admission to the Union. Music by Charles Diven Campbell. (W. C. Langdon).
Pageant of Yale University, New Haven, Conn. Probably the largest of all pageants in point of numbers. There were 7,000 performers. See COLLEGE DRAMATICS. (J. R. Crawford).
The Pageant of Bloomington and Indiana University. Music by Charles Diven Campbell. (W. C. Langdon).
The Masque and Pageant of Play, Northampton, Mass. (Margaret M. Eager).
The Cornell Pageant, Ithaca, N. Y. (Marjorie Barstow).
Shakespeare Festival, Columbia University. (Professor Abbott).
Shakespeare Masque, Wellesley, Mass. (Mrs. Laura Palmer Ingalls).
Shakespeare Tercentenary Masque, New York City. (Arthur Farwell, Percy Mackaye).
Cupid and Psyche, Yale School of Fine Arts, New Haven, Conn. (John J. Chapman, Horatio Parker, Jack Randall Crawford).
The New Vision, a Masque of Modern Industry, Buffalo, N. Y. (John Lund, Hazel Mackaye).
Shakespeare Tercentenary Civic Festival, Boston, Mass. (Lotta A. Clark).
Christmas Mystery, Duquesne, Pa. (Thomas Wood Stevens).
1917. Community Pageant, Boston, Mass. (Mrs. Pearl M. Keating).
Pageant of Womanhood, Boston, Mass. (Marie Ware Laughton).
Historical Pageant of Florida, Tallahassee, Fla. (Thomas Wood Stevens).
The Cornell Pageant, Ithaca, N. Y. (Marjorie Barstow).
The Drawing of the Sword, a war masque, Carnegie Institute of Technology, Pittsburgh, Pa. (T. W. Stevens, B. Iden Payne).
Caliban, by the Yellow Sands, a Masque, Boston, Mass. (Arthur Farwell, Percy Mackaye, F. Stanhope).
American Red Cross Masque, Huntington, L. I. (Joseph Linden Smith and T. W. Stevens).
Semi-Centennial Pageant, Drew Theological Seminary, Madison, N. J. (Marie Moore Forrest).
1918. Masque of the Titans of Freedom, George Washington and Abraham Lincoln, Urbana, Ill. (W. C. Langdon).

For complete lists of pageants, and for all details of construction, selection and production, music, costumes, etc., consult the bulletins of the American Pageant Association. See the articles COMMUNITY DRAMA, FESTIVAL, MASQUES, PAGEANTRY; also the bibliographies under those headings.

DUNCAN MACDOUGALL.

PAGEANTRY, pā'ên'trê. The production of pageantry has become prominent in America since the advent of the 20th century, in some respects following the longer established English models, but developing in others certain relations to the industrial and educational improvement of towns or smaller interior social groups, which give it a somewhat distinctive

character. This local improvement function may be traced in this country, especially since 1910, in the lists of "Civic Pageants" "Community Pageants," and sectional "Historical Pageants" which have been noteworthy in a number of our States. There has been all manner of pageantry production illustrative of varied topics, since its recent especial popularity has been established, but the development of it for the type of social group improvement cited above, has been characteristic of the members of the American Pageant Association, who have studied methods for its production in this way as a peculiarly useful agent for community vitalizing. An interesting element of this development in its use is that it has gone hand in hand with the gradually increasing recognition of the importance of recreational facilities in all our communities, urban and country districts, alike, and has added to this, substantial lessons in the historic associations of places in ways to increase citizens' pride in their localities, and further, has presented opportunities for illustration of local industries and publicity for them in such manner as materially, in almost every instance of such experiments, to give new impetus and prosperity to them. This form of pageantry and its application deserve thus to take a place as representative in this country, at least, and the procedure followed in producing it, and applying it in this special way, by those directors who have made it distinctive, is a valuable example for others wishing to organize such festivals with a like object, in their localities.

The director in this community improvement type of pageantry has either been a resident of the community, or has taken up residence there on purpose to familiarize himself with its interests and activities so that he may illustrate and advertise them properly in his pageant. Technically the procedure has been in the preliminaries, like any other organization of forces for public celebrations. An initial committee of the most substantial and energetic citizens is formed to support the enterprise financially and actively. In some instances of small communities of good promise, at the recommendation of the director, the enterprise has been financed initially by one or another of our philanthropic organizations instituted for educational improvement, such as the Russell Sage Foundation, which materially aided in the pioneer work of this special form of local improvement pageantry. It may be seen that a director in these enterprises, must be one able himself to see the possibilities in any given community, industrially and otherwise, and to know how the celebration of its history and activities through a festival of pageantry entered into by the citizens may be a means of advancing its local interests. He must also be confident and enthusiastic enough to inspire the citizens themselves with like belief in the enterprise. It becomes more than an ordinary public celebration, thus, bearing on the face of it the need of special qualities of social sympathy in the director, and a sincere desire to aid the prosperity of the community in which he organizes it.

With the initial committee in the community organized, and the ways and means seen clear for the support of its efforts, subcommittees are formed for the organization of such groups as will portray historic episodes in the produc-

tion, episodes illustrative of the industrial life of the place, and the further incidental scenes of a symbolic or lyrical nature usual in these pageants. A special committee takes charge of the costumes and properties, and another of arrangements for orchestral and vocal support to the performance.

In the notable pageants of this kind in this country, the director-in-chief is most frequently the author of the book and as well of the lay-out for production altogether, and sometimes of the music scheme, even if not the composer of the full score. For working out the detail special talent is engaged as a rule, and so far as possible this talent is called upon in the locality where the production is to be, since it is part of the object of these pageants to stimulate preferably, local abilities by giving them the opportunities the festival presents.

The performers are always local persons, in this representative type of pageantry, if the artists on the producing staff may not be always so. It has been the special aim of the pageant producers in these cases to inaugurate and maintain a strongly local social feeling in the preparation of their pageants, in order to make them peculiarly an expression of the *esprit de corps* of the townsfolk, recreationally and as to sympathetic interest and pride in their history, their industries and especially in the possibilities of their community in the matter of prosperity and growth. The representation through pageantry of the pioneer enthusiasm expended by their ancestors in founding a community, is employed to inspire its modern members with renewed confidence in their natural heritage of energy,—while spirited reproductions of scenes from their own current industrial life, encouragingly sum up their accomplishment, and its promise of prosperity.

In the small country communities where this recreational and educational festival has been tried, the people participating have been farmers and hardworking folks for the most part, but their rehearsals for their production have been enthusiastically attended and carried on, and have proved a source of social enlivenment for the two months or so required for them. Great interest has been taken in these cases, in the preparation of costumes and properties, in the unearthing of heirlooms and old possessions for use in these capacities, and, among the actors, in the reproduction of the life scenes in which they knew their own ancestors were actually the original participants. In such ways the pageantry produced in the rural districts and small country towns has had an intimate interest it has not had in the large urban communities—and similarly in the rural districts it has responded to a more unique need, a hunger for social enlivenment and need of industrial energizing.

William Chauncy Langdon, who has been a notable pioneer in the rural application of pageantry in this country—with those of his colleagues who have followed his example—has made it in noteworthy instances, actually an altruistic application of the arts to social improvement, in a most comprehensive sense. His work is thus under the head of purely amateur enterprise, in the best sense. It will be seen that the emphasis relative to its usefulness must be laid upon its ethical impulse, and the effect of this upon the public spirit in the place

Scene from the Stevens pageant, Rose Mary Garden Theatre, Huntington, L. I., showing fine sample of well-selected background, and fine spacing of groups for out of doors, also proper and beautiful uses of artificial adjuncts, and well-used water approach in the action

PAGEANTRY

Out-of-door auditorium and part of stage space, banked and beautified by appropriate natural means, of the Rose Mary Garden Theatre, Huntington, L. I. It shows an excellent arrangement of water-course to be used in the action of the Red Cross Pageant of Thomas Wood Stevens

of its production, rather than upon its features as a spectacle, or even as an artistic object lesson, although these pageants have served to discover and inspire local talents in the arts, in many instances, and by reason of expert and sympathetic direction of local amateur talent, have often resulted in artistic, and not alone ethical object lessons. They have been not crude, but excellent and beautiful in effect.

Relative to its technical form, the most noteworthy models have been arranged in general after the plan of structure of all the main types of pageantry, as established already in England, though varied and modified to fit local material to be illustrated by them, and accordingly to the taste of the director.

The usual outline of structure is as follows:

A.

A *Herald* presents a prologue, and enters thereafter between scenes to recite introductory or explanatory matter, fulfilling the function of a Greek chorus.

This herald is sometimes replaced by a chorus like that in Greek drama, which introduces the explanatory matter either directly through the words of songs, or symbolically through dance evolutions, or tableaux.

B.

The herald is often succeeded by a lyrical prelude of dance and music, the dance usually of the modern "Interpretative" order, symbolic of the subject of the pageant it introduces. Occasionally where it has been appropriate to the historical subject matter, folk dances or other conventional dances are introduced as prelude or interludes.

C.

The *First Episode* proper now takes place, following one or both of these introductory passages. It is usually a directly dramatic scene presenting some representative historic incident of the period or periods which contribute subjects to the pageant. Such incidents often focus about the person of a famous individual of the period or the locality which the pageant celebrates.

D.

The further dramatic scenes of the pageant follow in their order, to the conclusion, with usually lyrical symbolic interludes between each two of them, or some introductory recital by the herald, as has been stated. Sometimes the interludes are varied from the allegorical, fanciful type, and are constituted of scenes illustrative of the industries of the place, and their progress from early times. This would be in cases where the industrial development of the place was incidental to a main historical theme, and not in itself the main theme.

E.

The *finale* is tableau, epilogue, by herald, lyrical passage: one or more of them, in which are summed up in allegorical or at least poetic form, the main theme and moral, that is, the concluding argument, presented by the whole spectacle. A *march past* of all characters is also a frequent feature of the *finale*.

A certain unity of plot is preferably regarded in the plan of the successive dramatic scenes, a given relation of them to the theme or moral to be developed through the agency of the production. It has been the aim of the leading pageant producers to create a standard in the structure of these compositions. The American Pageant Association (see footnote) has aimed particularly to educate those who wished membership in its body, in the technical understanding of such dramatic planning of structure and detail as should make the pageants they produced distinctly artistic compositions, and not loose processional or panoramic affairs, with parts ill related to each other or to any concrete central theme. This artistic consistency and unity is regarded by the specialists in pageantry, in the production of no matter what type of pageant they present under the several heads in the technical classification they employ, a classification in which the main types are

termed: Panoramic pageant, dramatic pageant, epic pageant, pageant drama, dramatic festival, lyrical drama. The detail of distinctions among these is mainly useful to specialists, but briefly they may be stated as follows:

A Panoramic Pageant consists of a long series of scenes and incidents, depicting historical developments, and not strongly focused about one main event.

A Dramatic Pageant is focused about some main event and the moral to be deduced from it, and is more concrete accordingly in its form.

An Epic Pageant deals with some particular epic event and is treated romantically rather than with any emphasis on an ethical theme. In form it may be like the preceding, or still more concrete and focused on personal action and special period, as is the following —

Pageant Drama: A drama on a grand scale with a heroic and romantic theme, and produced with the spectacular features of pageantry, that is, splendor of group masses and broad lines of action throughout its scenes.

A Dramatic Festival is one in which spectacular features, dances, choruses, tableaux, etc., are co-ordinated in poetic or allegorical illustration of a chosen subject; or it is a celebration of the spirit of some holiday in such form as presents a well-composed spectacle, and does not consist of mere loose features in a haphazard merry-making.

A Lyrical Drama may be defined as one with dramatic theme and central action, but conveyed in poetic forms of discourse and song, and having its main features threaded, so to speak, upon choric passages, that is, passages of dance scenes, symbolic tableaux and group movements, and the like.

As to the theme of the usual pageant, which is of the historical and community improvement or educational order, it may be summed up as the moral and promise to be deduced from local or general history and from the special activities, political, industrial or educational of a place or epoch.

Pageantry in the United States and England during the period of its coming into such conspicuous recent popularity, peculiar specialization and application to community improvement has been used in this country and England to illustrate and improve local agriculture, manufacturing, commerce, arts and education. Pioneer life in our country has been a favorite theme, and incidents of the early settlers' contact with the Indians are introduced into most of our State historical pageants. (A reference to the specification of subjects in the lists of pageants in the foregoing article PAGEANT will indicate representative productions illustrating these several themes.) Pageantry is at its best out of doors, and the most noteworthy pageants of the local history type have been produced so. Certain types of pageantry, given indoors, would rather come under the head of epic dramas, heroic dramas on a grand scale, for as a rule, given in the limited setting of a theatre they are more appropriately composed in the more concrete dramatic forms. If, indoors, they yet have the character which is specifically one of pageantry—that is, the carrying of the plot or theme predominantly by group action, rather than the action of individual persons—they come properly under the head of pageantry, but in the classification of pageant-drama defined above, for they have in such case the features of both forms of composition.

A word relative to choice of special site for an out-of-door pageant will be practical for would-be producers.

A producer must have in mind the necessity of mutual adaptation of site and production to each other, and out of doors a site cannot be made to order to any great extent, and so must, so far as possible, be *found* to order. It is to be realized especially in select-

ing a site that in order to properly enclose the scene pictures, the choice should be made of space which is some approach to an amphitheatre in form. It needs at least, at a suitable distance from the central action space, sloping ground, or background, and if possible side-fringe of trees, rising ground or rock wall—something to give it frame and modified distribution of light to set off the action and aid effective entrances and exits.

Some body of water, a stream or pool, is apt to be indispensable to certain scenes of almost every out-of-door pageant. In country districts a site combining these needs to a sufficient extent is usually possible to find. Production in other localities, large outdoor arenas, athletic fields, etc., may require artificial aids to the spectacular effects. The more artificial aids may be dispensed with, however, the better for the beauty of the outdoor production in every case. A wooden platform is an abomination out of doors, as also are artificial scenery pieces. If such must be used, a camouflaging of leafage should be employed to conceal their unreality which in the open air is wholly devoid of the illusion with which indoor lighting softens it.

The choice of colors for out-of-door productions is also one requiring special study given it in every instance. More brilliant colors and combinations may well be used out of doors and at the greater distances covered than are permissible indoors. The effects of light and shadow in a special site, should be considered and utilized in grouping and in application of color schemes. The effects of distances in the scene space, relative to the action of groups and individuals, must be experimented with by the director. No outdoor site may have the rules of the indoor theatre applied to it without modification and special adaptation. The matter of acoustics is also an important one out of doors. Because the use of the voice out of doors is more difficult than indoors, the lines of pageantry are as a rule reduced to their simplest possible compass, enough to carry the needed information and little more. But this must be done with good dramatic speech, with as much beauty as possible in language. But particularly is it necessary to remember that a strictly rhythmic prose, or a well-turned pentameter verse will enable a speaker to make his voice carry out of doors, with more ease than lines written without regard to rhythm or the quality and juxtaposition of syllabic sounds they contain. This presents another problem for the writer of a pageant book, for the new pageantry which is to maintain an artistic standard of composition and production. It is well wherever possible to plan the action on a pageant site where the natural background of wooded land, rocks or walls may be made available as a sounding board for what dialogue enters the scenes, for the recitations of the Herald, or the singing of the choruses. If nothing whatever is naturally provided in the available locality, artificial backgrounds for this purpose may be erected, but should always be camouflaged with such effects as will relate them beautifully or appropriately to the setting which nature provides. The actor as well as the playwright has a problem here in the use of voice in the open

air, for speech. An utterance not too quick, with precise regard to rhythm in phrasing, and to rounded tone, is essential. It is for this reason that for important character rôles in pageantry and outdoor plays, professional actors are sometimes indispensable, or a risk of loss of the dialogue to the audience is incurred. But the director who is experienced or who will experiment with care in each new site, can aid clever amateurs to properly deliver their dialogue, or will know whether it can only be properly delivered by a professional actor who can adapt himself to difficult acoustics in a site where they are imperfect and cannot be improved. English pageantry is notable for its substantial magnificence of spectacular effects and costuming, and as a rule, for a higher literary type of book than our American pageantry—as yet. With more finish in this last respect, and with the adaptation of a more solid magnificence like that of the English pageantry, added to the theatric aptness in attaining picturesqueness and telling action which our own producers show on occasions, a highly artistic type of heroic, dramatic and spectacular composition may be developed from our American Pageant forms as they are now constructed and produced by their representative directors and the authors and composers who contribute to them. Consult Craig, A. T., 'The Aesthetic of an Outdoor Play' in *Drama* (May 1918). See PAGEANT.

FOOTNOTE.—The American Pageant Association was formed in 1911-12, for the express purpose of bringing together teachers, dramatic writers and producers, social settlement directors, and playground leaders, who were interested in this valuable form of elaborating their recreation periods, in schools or community centres, in sociological work in larger civic fields, or in producing entertainments for artistic education, and so on, that they might give each other the benefit of their several experiments in the development of this form of dramatic production and its kindred forms, technically, and as to working organization, that is, as an art, and as an educational social force. Its founder and president was William Chauncy Langdon. Its first members were: Percival Chubb, Peter W. Dykema (now of Saint Louis and University of Wisconsin, respectively), Percy Mackaye, Thomas Wood Stevens, Constance d'Arcy Mackaye, Hazel Mackaye, Elizabeth Hoar, Charles Farnsworth and Mrs. Charles Farnsworth (of Teachers College), Frank Chouteau Brown, Lotta Clarke, William E. Bohn, Anne Throop Craig.

ANNE THROOP CRAIG.

PAGET, pāj'it, SIR James, English surgeon: b. Great Yarmouth, Norfolk, England, 11 Jan. 1814; d. London, 30 Dec. 1899. He studied in Saint Bartholomew's Hospital, London, became a member of the Royal College of Surgeons in 1836, and a fellow in 1843. He was a corresponding member of the Institute of France. He was consulting surgeon at Saint Bartholomew's Hospital, and sergeant-surgeon to the queen, and was created a baronet in 1871. He was vice-chancellor of the University of London, president of the Royal College of Surgeons, and delivered many important lectures on his surgical work. He discovered the cause of trichinosis in 1836, and made great advances in the study and treatment of tumors, of diseases of the bones and joints, and neurotic cases exhibiting surgical symptoms. He also contributed to the advance of physiological research. A disease of the breast and osteitis deformans, a bone disease, are known after him. He published 'Lectures on Surgical Pathology' (1853); 'Clinical Lectures' (1875); etc.

PAGET, Violet ("VERNON LEE"), English essayist and critic: b. 1856. Since 1871 she has made her home in Italy, devoting herself in the main to the study of Italian art and literature. She is a brilliant though not always a convincing writer, fluent and discursive, and not infrequently subtle as well, and possesses the power of holding the reader's interest, no matter what subject be chosen. Among her works, all of which have appeared over the signature of "VERNON LEE," are 'Studies of the 18th Century in Italy' (1880); 'Belcaro: Essays on Sundry Aesthetic Questions' (1882); 'Ottile: an 18th Century Idyll' (1883); 'Euphorion,' essays (1884); 'Miss Brown,' a novel (1884); 'Juvenilia,' essays (1887); 'Renaissance Fancies and Studies' (1895); 'Limbo,' essays (1897); 'Genius Loci' (1899); 'Hortus Vitæ: Essays on the Gardening of Life' (1903); 'Genius Loci' (1905); 'Pope Jacynth' (1905); 'The Enchanted Woods' (1905); 'The Spirit of Rome' (1905); 'Sister Benvenuta' (1906); 'The Sentimental Traveller' (1907); 'Gospels of Anarchy' (1908); 'Laurus Nobilis' (1909); 'The Tower of Mirrors' (1914); 'Louis Norbert' (1914).

PAGO, pā'gō, island of the Adriatic in the bay of Quarnero and district of Zara, Dalmatia; a Jugo-Slavia possession. The canal of Morlacca separates the island from the mainland. Area, 81 square miles; pop. 7,000. The capital city, bearing the same name, lies in the deep Valone di Pago, which is hemmed in on every side save where the Bocca di Pago gives approach; the city has important saltworks and a population of about 4,000.

PAGO-PAGO. See PANGO-PANGO.

PAGODA, pā'gō-dā, a word of antique Persian origin meaning an idol-temple. It is now applied to almost any building in India, Burma or China, having a tower-like form and built for religious or memorial purposes, as, for example, a Buddhist tope, or one of the highly ornamented, bell-shaped dagobas of Burma. In its properly restricted sense, however, the pagoda is a form of tower peculiar to China and indicative of the ancient nature-worship that has given way only superficially among the common people to the imported doctrines and services of Buddhism, Islam and other introduced cults.

These beautiful towers are scattered all over the empire in thousands and are the most characteristic feature of the landscape; but in southern China great numbers were destroyed in the wars of the last century. They are always polygonal, have massively thick walls intended to last for centuries, and invariably have an odd number of stories, in some cases as many as 13, and rising to a height of 200 feet. The material is usually brick, but sometimes cut-stone is used, and each story is indicated by a projecting roof-like structure, curving upward at the eaves, and hung with bells or other pendants. These eaves give the whole an appearance of a pile of tile-roofed houses terminating in a peaked roof. Pagodas are usually highly ornamented and often are covered with glazed and colored slabs of potteryware, rarely with metal. The celebrated porcelain pagoda of Nanking, destroyed from superstitious motives by the Tai-ping rebels in 1853, was very high,

and was faced with blocks of fine blue porcelain.

The interior of a pagoda may contain statues and figures of mythical deities and thus have the significance of a temple, or it may be erected as a memorial of some great man or event and furnished only with descriptive tablets. Every one has been built by private munificence.

The idea prompting the erection of most, if not all pagodas is religious, standing in close connection with *feng-shui* (literally, wind and water), the strongest of Chinese doctrines or superstitions, for they exert, as the people believe, a most powerful influence in controlling certain supposed currents in earth and air, which are held to be important agents in modifying for better or worse climate, crops, health and even the ordinary actions of man. It was fear of this geomantic influence, possibly hostile to their plans, that led to the pagodas being thrown down all along the Yang-tze Valley by the Tai-pings, so that only a single one of importance now remains near that river.

PAGSÁN, pāg-sān', a mountain on the island of Luzon in the Philippines, a peak of the Cordillera del Norte, on the intersection of the boundaries of Ilocos Sur, Cagayan and Ilocos Norte provinces; height, 7,330 feet. At Pagsán a spur leaves the main range, which forms the boundary between Ilocos Sur and Ilocos Norte. The southern slopes of Pagsán are drained by the Anayan and the Calúan, which unite to form the Tinog River, a tributary of the Abra.

PAGURUS, or **PAGURIDÆ**. See HERMIT-CRABS.

PAHANG, pā-hāng', Indo-China, one of the federated Malay states under British protection, on the east coast of the Malay Peninsula, between 2° 28' and about 4° 50' N. and 101° 30' and 103° 30' E., to the north of Negri Sembilan and Johor, east of Perak and Selangor, south of Kelantan and Trengganu and west of the bordering China Sea. The state is 210 miles long, 130 wide, with 112 miles of coast and an area of about 15,000 square miles. It takes its name from the Pahang River, which drains the region and is navigable for large river boats 200 miles from its source, but too shallow for commerce of importance. Pahang in ancient times was called Indrapura. It was ruled by the Siamese until the 16th century; then by refugees from Malacca, who founded a royal line, between the members of which there was bitter war in 1855-65. In 1887 a treaty was signed with the British governor of the Straits Settlements; in the following year a British resident was appointed to protect British interests, but disorder broke out again and was only quelled by the armed interference of the Straits governor; in 1895 Pahang joined the Malay Federation. The state is fertile with regular and sufficient rains and is cooler than the western coast of the peninsula. The important industry of Pahang is gold-mining; the Raub mine and other lodes along the river are successfully worked by European capital; electricity is carried to the mines seven miles distant by overhead wires. The population is about 90,000; 134 being Europeans and Americans; about 70,000 Malays and aborigines of other stocks; the rest Chinese and Hindus, especially Tamils. The

capital is Kuala Lipis; there are four administrative districts.

PAHARIA, or **MALER**, a northern section of the Dravidian race, inhabiting the Rajmahal Hills, Bengal, India. See **DRAVIDIAN**.

PAHLANPUR, or **PAHLUMPUR**. See **PALANPUR**.

PAHLAVI (pā'la-vē) or **PEHLEVI LANGUAGE**. See **PERSIA**, **LANGUAGE AND LITERATURE**.

PAHLEN, pā'lēn, **Peter Ludwig**, COUNT OF, Russian statesman: b. Palms, Esthonia, 28 April 1745; d. 1826. He fought in the war with Prussia (1761-62), against Turkey (1769) and against Sweden; was ambassador to Sweden (1790); was governor-general of Courland (1795) and later of Finland: was made a Russian count in 1799 and Prime Minister, Foreign Minister and military governor of Saint Petersburg in 1800. These high offices he used to further the conspiracy against the Tsar Paul I, which resulted in the assassination of that monarch in 1801. Alexander I distrusted Pahlen and retired him. His son, **PETER** (1778-1864), a great Russian general, fought in Asia in 1796; against the French 1812-14; and in Poland in 1831. He was Russian Minister to Paris from 1835 to 1841. His younger brother, **FREDERICK** (1780-1863), was Minister to Prussia, to Rio Janeiro and to Munich, a signatory of the Treaty of Adrianople in 1829 and later governor of Khereson.

PAHOEHOE, a Hawaiian term used to describe moderately smooth to billowy lava surfaces, as contrasted with the roughly craggy and cindery types known as aa.

PAILLERON, pā-yè-rōn, **Edouard Jules Henri**, French dramatist: b. Paris, France, 17 Sept. 1834; d. there, 19 April 1899. He was a clerk in a notary's office until 1860, when his first work, a volume of satirical poems and a play, was published, after which he devoted himself to literature. His plays, written in both prose and verse, attained considerable popularity. He was elected to the Académie Française in 1884 as a result of the success of his 'Le Monde ou l'on s'ennuie' (1883). Among his plays are 'Le Mur mitoyen' (1861); 'L'Age Ingrat' (1879); 'La Souris' (1887), etc.

PAIN, **Barry**, English humorous author and journalist: b. 1867. He was educated at Cambridge, was for a time an army tutor and in 1890 removed to London. He has published 'In a Canadian Canoe' (1891); 'Playthings and Parodies' (1892); 'Stories and Interludes' (1892); 'Graeme and Cyril' (1893); 'Kindness of the Celestial' (1894); 'The Octave of Claudius' (1897); 'Wildmay and Other Stories of Women' (1898); 'Romantic History of Robin Hood' (1898); 'Eliza' (1900); 'Another English Woman's Love Letters' (1901); 'The One Before' (1902).

PAIN, a sensation felt in animal bodies, always disagreeable and varying in degree from a slight uneasiness to intense agony. It is a very important sign in some diseases and is nearly always associated with an inflammation, an ulceration or a solution of continuity in some of the tissues of the body. But in health

also certain sensory stimuli, the general tendency of which is hostile to the welfare of the organism, are capable of producing pain. Gröninger stated that the essence of pain lies in a disturbance of the organization of the nerve at some point in its course. It has, however, been shown that pain is a distinct sensation, not to be confused with mere unpleasantness and on the skin localized in spots not sensitive to pressure or temperature. Those parts of the body which are most subject to injury are supplied with nerves in the largest quantity.

Were it not for sensibility to pain, important parts of the body might be irreparably injured without the knowledge of the individual. This sensibility undoubtedly differs in degree in both men and animals. Persons of a highly excitable temperament usually feel pain intensely, especially if they are predisposed to neuralgia. Pain is called acute, when sharp and violent; lancinating, when of a stabbing or darting character; lacerating, when there is the sensation of tearing; burning, when it resembles the pain of a burn. Pains are also distinguished as smarting, stinging, griping, bearing-down, gnawing, biting, etc. These differences do not reside in the quality of the sensation of pain itself, which is uniform, but in the concomitant sensations. The degree of pain is not always in proportion to the gravity of a disease and may be masked by other symptoms in a severe affection. Extensive ulcerations may occur in the stomach and intestines, for example, attended with very little pain. Cartilage is believed never to be the seat of pain. Pathological changes in insensitive parts of the body, however, may cause pain. Pain is frequently sympathetic or reflex, occurring in a portion of the body remote from the seat of disease or irritation; for example, in disease of the hip-joint pain is felt in the knee. The feeling of pain is always referred to the periphery of the sensory fibres, no matter what portion of the sensory tract has been irritated. 'Lesions of the brain are rarely accompanied by sensation in that organ, but often by severe pain referred to the extremities.' Under certain conditions the sense of pain may be lost independently of the other sensations.

While pain is but a symptom, it should, if possible, be relieved, though the cause may not be removed. Painful sensations are associated with a depression of the circulation. Pain exhausts nervous energy, interferes with sleep, interrupts the appetite and digestion, and if long continued may shorten life. For treatment, remove the cause, enjoin rest, apply locally hot water or poultices, sinapisms, counter-irritation, and anodyne linaments. Anodyne or narcotic drugs, although of value, should be used cautiously. Regulation of the diet and attention to the condition of the bowels is important.

PAINE, **Albert Bigelow**, American author and editor: b. New Bedford, Mass., 10 July 1861. He was educated in the public schools of Xenia, Ill. From 1899-1909, he was editor of the League department of *Saint Nicholas Magazine*. Among his works are 'Rhymes by Two Friends' (1893); 'The Autobiography of a Monkey' (1897); 'The Bread Line' (1900); 'The Ship Dwellers' (1910); 'Mark Twain: A Biography' (1912); 'The Boys' Life of Mark Twain' (1916); 'Mark Twain's Letters' (1917).

PAINE, Charles Jackson, American sports man: b. Boston, Mass., 26 Aug. 1833; d. 12 Aug. 1916. He was graduated at Harvard College and entered the army as captain of the 22d Massachusetts infantry 8 Oct. 1861. He served with distinction during the Civil War; was appointed brigadier-general of volunteers in 1864; and in 1866 was brevetted major-general. He became prominent as a yachtsman. The *Puritan, Mayflower* and *Volunteer*, owned by him, were successful defenders of the America's cup.

PAINE, John Alsop, American archaeologist: b. Newark, N. J., 1840; d. 1912. He received his education at Hamilton College and at Andover Theological Seminary. He conducted botanical work for the board of regents of the State of New York in 1862-67 and in 1867-69 held the chair of natural science at Robert College, Constantinople. In 1872 Paine was archaeologist to the expedition sent out to the district east of the Jordan by the Palestine Exploration Society. In 1889-1906 he was curator of the Metropolitan Museum of Art in New York City.

PAINE, John Knowles, American organist and composer: b. Portland, Me., 9 Jan. 1839; d. Cambridge, Mass., 25 April 1906. In 1858-61 he studied in Germany, in 1862-73 was instructor in music at Harvard and in 1875 became professor of music there. He composed the music for the 'Edipus Tyrannus' of Sophocles, as performed in the original at Cambridge in 1881; the 'Centennial Hymn' to Whittier's words for the Exhibition at Philadelphia in 1876, and the Columbus march and hymn of the World's Columbian Exposition of 1893. Among his further works are the opera 'Azara'; 'Spring Symphony'; the cantatas, 'The Nativity' and 'The Song of Promise'; choruses to Aristophanes' 'Birds'; symphonic poems; music to the 'Tempest'; and an overture to 'As You Like It.'

PAINE, Martyn, American physician: b. Williamstown, Vt., 1794; d. 1877. In 1813 he was graduated at Harvard and from 1816 to 1822 practised his profession at Montreal, Canada. In the latter year he removed to New York City. He was one of the founders of University Medical College in 1841, which afterward became the medical department of New York University, and where Paine was professor of medicine and materia medica in 1841-67. He published 'Cholera Asphyxia of New York' (1832); 'Medical and Physiological Commentaries' (1840-44); 'Institutes of Medicine' (1847; 9th ed., 1870); 'Review of Theoretical Geology' (1856).

PAINE, Robert Treat, signer of the Declaration of Independence: b. Boston, 11 March 1731; d. there, 11 May 1814. He was graduated at Harvard at 18, studied theology, was chaplain to the New England troops in 1755, and in 1759 was admitted to the bar and began to practise law in Boston. He represented Taunton in 1768 at the convention called to discuss Sir Francis Bernard's dissolution of the general court; conducted the prosecution of Preston and his men for the Boston Massacre (1770), and the impeachment of Peter Oliver for receiving money from the king and not from the colony; served in the general assembly of the State (1773-74), in the Pro-

vincial Congress (1774-75), and in the Continental Congress (1774-78), being a signer of the Declaration and a member of various important committees. He was a delegate to the State convention of 1779, which adopted a constitution; was attorney-general of Massachusetts (1780-90); and sat as judge of the Supreme Court (1790-1804). Consult Sanderson, J., 'Biography of the Signers of the Declaration of Independence' (Philadelphia 1823).

PAINE, Robert Treat, American poet, son of the preceding: b. Taunton, 9 Dec. 1773; d. Boston, 13 Nov. 1811. His baptismal name, Thomas, was changed in 1801 by act of Legislature, that he might bear his father's name and not that of the famous deist. He was graduated at Harvard in 1792, was then in business for a time, but devoted most of his attention to journalism and poetry. His journal, the 'Federal Orrery,' was given up after two years. His marriage with an actress in 1795 shut him out of Boston society and alienated his father. The son practised law with some success and much brilliancy, but he soon fell into wayward courses and died in poverty. His best known poems, which were popular, but practically without value, were 'The Invention of Letters,' delivered at Cambridge in 1795; 'The Ruling Passion' (1797); the patriotic song, 'Adams and Liberty' (1798); and the bitter political poems, 'The Jacobiniad' and 'The Lyars.'

PAINE, Thomas, political and religious radical: b. Thetford, Norwalk, England, 29 Jan. 1737; d. New York, 8 June 1809. His father was a Quaker staymaker. Paine thought of being a sailor, and made one small voyage, then was a staymaker at Sandwich, Kent, a tobaccoist at Lewes, Sussex, and an exciseman. He was discharged from the excise in 1765, but three years later received another appointment at Lewes, Sussex, being dismissed in 1774. In London he met Franklin who gave him letters of introduction to leading men in America. In 1774 he separated from his wife, for causes that are not clear, and came to America, arriving in Philadelphia in December 1774. Here he became the editor of the *Pennsylvania Magazine* for 18 months. Hostilities having commenced between the mother country and the colonies, Paine wrote his well-known pamphlet, 'Common Sense' (1776). The object of this pamphlet, written with much vigor, was to recommend the separation between the Colonies and Great Britain. After war was declared he gave up his position on the magazine and joined the staff of General Green. In 1777, while with the army, he wrote the first of a series of political appeals called the *Crisis*, the first number of which started with the words, 'These are the times that try men's souls.' This was written at a time when the American cause seemed lost. But in every village and city in the colonies, the burning words of Paine, which were also ordered read to the army, aroused new courage. Other numbers of the *Crisis* were published at short intervals. He left the army to become secretary to the Committee of Foreign Affairs. In January 1779 he resigned from his secretaryship because of a controversy with Silas Dean, whom Paine accused of attempting to profit by his agency by conveying secret supplies from France. But in November of the same year, the State

of Pennsylvania testified that it approved of Paine's position in this matter, by appointing him clerk of the assembly. While clerk on a salary of \$2,500 he started the subscription which resulted in the forming of the Pennsylvania Bank (later known as the Bank of North America). In 1785 Congress, in recognition of his services during the war, voted to him the sum of \$3,000. The State of New York also gave him 300 acres of land in New Rochelle. In 1787 he embarked for Europe, carrying with him his model of his iron bridge, on which he had spent many years. He went first to Paris, and then to England. On the appearance of Burke's 'Reflections on the French Revolution' he wrote the first part of his 'Rights of Man' in answer to Burke. The second part was published in 1792, and on the 21st of May of that year the government issued a proclamation against wicked and seditious publications and, though not naming, alluded to the 'Rights of Man.' On the same day the attorney-general started a prosecution against Paine. Paine escaped into France where he was chosen a member of the National Convention, by two districts of France, and became the member from Calais. In the convention he became one of the leading figures. At the trial of Louis XVI he voted against the sentence of death and urged that the king be imprisoned and then banished to the United States. This conduct offended many, and in 1793 he was excluded from the convention on the ground that he was a foreigner (although he had been naturalized). He was arrested and committed to the Luxembourg. Just before his confinement he had finished the first part of his 'Age of Reason' on which he had been working for years. This he gave to a friend, Joel Barlow, and it was published in London and Paris in 1794. On the fall of Robespierre he was released from prison, after a narrow escape from death, and again took his seat in the convention. In 1795 the second part of his 'Age of Reason' was published, and the third part in 1807. 'The Age of Reason, being an Investigation of True and Fabulous Theology' created the greatest stir of any book of its time. It caused a change in the public feeling toward him, and lost him his friends in America. Considered at that time a bitter attack upon religion, it is seen to-day that it only presented the deism of the 18th century. In May 1796 he addressed to the Council of Five Hundred a work called 'The Decline and Fall of the System of Finance of England,' and also published a pamphlet, 'Agrarian Justice.' In October 1802 he arrived again in America, after a controversy with Washington, landing at Baltimore. He found that his former friends had turned against him, and that his 'Age of Reason' caused him to be looked upon with suspicion. For some years he lived on his farm at New Rochelle. He died in New York 8 June 1809, and was buried on his own farm. In 1819 his bones were taken to England by William Corbett, but were refused burial, and were scattered throughout the land. Paine has received such strong extremes of praise and execration that it is hard to form a clear picture of the man. The only source of unbiased information regarding him must be found in his own writ-

ings. He took a leading part in the political affairs of at least two countries, France and the United States, and was a deep lover of liberty. He possessed much native vigor of intellect and was a writer with a spirited argumentative style. Washington, Jefferson, Franklin and Randolph have praised highly his efforts and contributions to the cause of the colonies. It might be added that but for his attacks upon religion, Paine's position would be higher. But his 'Age of Reason,' unscholarly as it was, in many ways broke ground for the serious biblical criticism that was to come. It was written not to attack religion but, in his own words, "to show a higher form of religion." Paine was not an atheist, as has been popularly believed, nor are the popular stories of his drunkenness true. His services to the American cause were lasting and important. The political pamphlets, letters and addresses of Paine, which were many, may be found in his works. Conway published the best edition of Paine's works in 1893-96. The earlier lives of Paine, 'The Life of Thomas Paine,' by James Cheetham (New York 1809), 'The Life of Thomas Paine' by Francis Oldys (London 1791) are marked with bitter hatred for Paine and do not give a true picture of his life or works. The 'Life of Thomas Paine' by M. D. Conway (1892), is the standard. Consult his works, edited by M. D. Conway, of which there are several editions; also Taylor's 'Literary History of the American Revolution' (1896).

PAINESVILLE. A city 29 miles north-east of Cleveland, Ohio, the county-seat of Lake County, connected by the Lake Shore and Michigan Southern, the New York, Chicago and Saint Louis and the Baltimore and Ohio railroads and by electric lines to Ashtabula, Fairport and Cleveland. It contains many industrial establishments, a grain elevator, flour mills, iron foundries, machine shops and brick yards. The municipality owns and operates its own waterworks and electric plants for lighting the town. It receives considerable commercial importance from the fact that Fairpoint, making a fine natural harbor on Lake Erie, is but three miles away. The town boasts of a large public library, containing over 5,500 volumes, and a non-sectarian college for women (Lake Erie College) which dates as far back as 1859. The town itself was founded in 1800-1802, but was not incorporated before 1832, receiving its present charter as late as 1902. The rich agricultural and mining region in which Painesville is situated contributes considerably to its prosperity. Pop. 7,272.

PAINLEVE, pân'lê-vă', Paul, French mathematician, scientist and statesman: b. Paris 1863. He studied at the École Normale Supérieure 1883-86, graduating docteur ès sciences in 1887, the same year being member of a mission to Germany. From 1887-92 he was instructor in mechanics at the University of Lille, became lecturer at the Sorbonne, from 1895 to 1903 taught mathematics at the École Normale, was appointed professor of mathematics at the University of Paris and later at the Polytechnique. In 1900 he was elected a member of the Institut. In October 1915 Briand appointed him Minister of Public In-

structions and Inventions for Public Defense and in 1917 he became Minister of War. His published works are 'Leçons sur le frottement' (1895); 'Leçons sur la théorie analytique des équations différentielles' (1897), and with Emile Borel 'L'Aviation' (1910; German trans. 1911).

PAINS AND PENALTIES, Acts of. An act of legislation passed in England providing for the imposition of punishment without trial upon anyone clearly guilty of treason or similar serious crimes. No capital punishment, however, can be imposed under this statute. In the United States such legislation never has been enacted, nor ever could be, since there is a constitutional clause forbidding all bills of attainder.

PAINT. Coloring material prepared for coating a surface and thereby distinguished from dyeing or staining matter.

History.—The ancient full gamut of pigments consisted of: White, an earth from Melas; red an earth called *sinapis* (red ochre) from Cappadocia; yellow from the Attic silver mines; black, from charred plant life. Green appears next in their category brought from the copper mines; then followed the imperial purple of Tyre. White lead was used by the ancients, being found near Athens in form of a face powder in a pottery box dating from 400 B.C. Theophrastus, Pliny and Vitruvius give a description of its manufacture from lead and vinegar (as used to this day); it is later known as "minium album." Yellow ochre was used by the Egyptians, Greeks and Romans; Theophrastus terms it "oichra." Pots of it were found in the Pompeii ruins. Naples yellow, as a true antimonial yellow, is found in the yellow enamel of Babylonian bricks, 2,500 years old, and 13th century pottery of Persia contains such a yellow. Verdigris pigment (*viride Græcum*) was used by the Romans. Theophrastus, Pliny and Vitruvius show vermilion (cinnabar) was known in their day. Indigo has been used by the East Indians from very distant times and also by the ancient Egyptians; Pliny calls it "indicum." The Chinese have been producing Indian ink for over 2,000 years.

Pigments: Their Nomenclature and Composition.—Pigments technically are dry substances, usually in pulverized form, or in lumps easily pulverized, which by the addition of a liquid medium, technically called a vehicle or carrier, are applied by painters to surfaces which it is desired to color. Pigments are properly restricted to the dry coloring matters which enter into the composition of paints but the word is frequently used as a synonym for paint. A pigment is therefore a "color," the word "color" being used indiscriminately of a compound of various pigments, or of a ground pigment ready for the addition of the suitable oil or carrier. Thus in the commercial world the pigments put up in cans ready for use at paint stores are commonly termed "colors." Strictly speaking, the term pigment should not be applied to any substance unless it has the inherent power of its own to impart color to other substances with which it may be mixed. Adjunct substances such as starch, glue, finely ground siliceous, quartz, etc., possessing no coloring matter of their own are often added to true pigments with no other purpose than that of

adding weight without changing the original color of the pigments in combination and by some manufacturers are termed pigments although not entitled to the name.

In this article all pigments have been classed into groups of certain colors, and under each group are treated all which belong to it by being nearer in tone than to any other group. The whites are first considered as this group is the most important of all, nine whites form the base upon which nearly all tints are made by the addition of colored pigments. White lead is the best known and most important of the white group. Although known from ancient times it has only been manufactured on a large scale for a little over 200 years. The usual process employed in its manufacture is that known as the "Dutch process"—a chemical process in which there is produced the corrosion of the lead metal by the agency of dilute acetic acid fumes, carbonic acid, hydrogen, oxygen and heat.

WHITES.

White Lead.—Composed of about 75 per cent lead carbonate and 25 per cent lead hydroxide. "Dutch Process" is made by slow double corrosion in the presence of acetic acid (vinegar) and carbonic acid from fermentation of tan bark or dung. "Quick Process" is by direct action of acetic acid, the acetate of lead subjected to carbonic acid gas. The former is the better product.

Flake White (white lead, ceruse, blanc d'argent, blanc de plomb, Kremser Weiss).—A purified white lead.

Lead Sulphate (Freeman's white lead).—Little used on account of many defects.

Sublimed White Lead.—Composed of 75 per cent lead sulphate, 20 per cent lead oxide, 5 per cent zinc oxide.

Calcium Carbonate (Paris white, whiting, alba whiting, white mineral primer).—Very inferior for paints.

Zinc White (Chinese white, blanc de zinc, Zinkweiss).—An oxide of zinc, producing a very hard, brittle, vitreous surface.

Baryta White (permanent white, blanc fixe, Permanentweiss).—Made, as its name implies, from barytes.

Lithopone (oleum white, Beckton white, Charlton white, ponolith, Jersey Lily white, Orr's white).—A double precipitate of sulphide of zinc and sulphate of barium.

Sulphopone.—Similar to the last named but sulphate of calcium displaces sulphate of barium.

YELLOWS.

Yellow Ochre (Roman ochre, golden ochre, mineral yellow, brown ochre, Oxford ochre, ocre, jaune, gelber ochre).—A ferric hydrate. The mineral usually contains silica, gypsum, iron and copper purities as impurities.

Cadmium Yellow (Orient yellow, aurora yellow, orange cadmium, sulphide of cadmium, Jaune brilliant, jaune de cadmium, Cadmium-gelb).—Cadmium sulphide.

Aureolin (cobalt yellow, Jaune de cobalt, Kobaltgelb).—A compound of the nitrites of cobalt and potassium. Very transparent in oil or water color.

Lemon Yellow (baryta yellow, barium chromate, yellow ultramarine, permanent yellow, jaune d'outremer).

Gamboge (gomme-gutte, Gummigutt).—Yellow pigment of the gum resin *Garcinia*. A mixture of water-soluble gum and a resin soluble in alcohol, chloroform, etc. Unstable as water-color, but in oil (if a resin be added) appears to stand light.

Indian Yellow (piuri, purree, peori, jaune indien, Indischgelb).—Made at Monghyr, Bengal, from cow-urine. It is an impure salt of euxanthic acid. Unstable in linseed oil, more durable in poppy; quite durable in water-color.

Mars Yellow (Mars orange, artificial ochre, jaune de Mars).—Species of artificial ochre produced by precipitating an iron salt (usually green vitriol) with alum by the agency of caustic soda, potash or lime. Permanent if carefully prepared.

Naples Yellow (jaune de Naples, jaune d'antimoine, Neapelgelb, giallo di Napoli).—Under this title are: (1) The English mixture of cadmium yellow or a deep cadmium with a white; (2) the true Naples yellow—a basic lead antimoniate. The first (imitation) is permanent in oil, the latter liable to darken if sulphuretted hydrogen gets at the lead. As a water-color it quickly darkens.

Yellow Lake (brown pink, citrine lake, yellow madder, Italian pink, quercitron lake).—Best is obtained from quercitron bark. Formerly prepared from Persian, Turkish or Avignon berries. None recommended for artists' colors because very fugitive in oil or water-colors.

Chrome Yellow (chrome, chromate of lead, jaune de chrome, Chromgelb).—Should be neutral lead chromate of pure yellow tint. Orange and reddish hues obtained by adding lead oxide. All lead chromates are fugitive more or less but last longer preserved in oil varnish.

Burnt Ochre (American sienna).—Made from raw sienna with high percentage of ferric oxide and is mahogany color. Not favored because muddy.

Vanadium Yellow.—Costly and very fugitive.

King's Yellow (orpiment, jaune royal, Königsgelb).—Yellow arsenic sulphide. Very lovely but fades badly in oil or water-color.

REDS.

Vermilion (cinnabar, vermilion, Zinnober).—Ground mineral mercuric sulphide.

Madder (pink madder, rose madder, madder carmine, madder red, Rubens madder, madder purple, madder lake, madder brown, carmin de Garance, laque de Garance, Krapplack).—Produced from madder plant or artificially from alizarin and purpurin (anthracine derivatives). The madders are not truly permanent.

Mineral Lake (pink color, laque minerale).—A precipitate, caused by the action of neutral potassium chromate solution with a stannic chloride solution, dried and calcined. Strictly permanent.

Light Red (burnt ochre, rouge anglais, brun rouge).—Should be burnt yellow ochre, a permanent pigment.

Venetian Red (rouge, crocus, colcothar, caput mortuum vitrioli).—At first was a native ferric oxide or red hematite less purplish than Indian red, but is now artificial ferric oxide from calcining green vitriol. Less brownish than light red. Permanent.

Indian Red (Persian red, Indian red ochre).

—Made from red ochre or red hematite. Has slightly purplish tinge and contains about 95 per cent ferric oxide. Most comes from India, where it is native, but some is calcined. Genuine is permanent.

Red Ochre (red hematite, red iron ore, scarlet ochre, red chalk, ruddle, bole, sinoper, sinapis, rubrica, miltos, terra rosa).—All are native ferric oxide or iron peroxide combines in different proportions of clay, chalk and silica, and range from cherry red, reddish brown, to yellow brown. Italian terra rosa shows pinkish tinge (probably artificial).

Para Vermilion.—A para-nitraniline lake. One marketed shows 90 per cent barytes, 5 per cent zinc oxide and 5 per cent para-red. Soluble in linseed oil.

Indian Lake (lac lake, Lack-lack).—Lac resin secretion of the East Indian lac insect. (see LAC). Less fugitive than crimson lake, more so than madder.

Carmine and Cochineal Lakes (carmin, laque cramoisie, crimson lake, purple lake).—Precipitated coloring matter of the cochineal insect. (See COCHINEAL). Very fugitive.

Red Lead (minium saturnine, mine rouge, mine orange, mennige, rosso saturno).—Beautiful orange red composed of two molecules protoxide of lead with one molecule binocide. Quickly discolors in contact with sulphuretted hydrogen. Not practical for water or oil.

GREENS.

Terre Verte (green earth, terre de Verone, grüne Erde, terra verte).—The earth minerals glauconite and celadonite. Very permanent in oil or water-color.

Viridian (emerald oxide of chromium, vert pannelier, vert de Guignol, vert emeraude, Mittler's green).—Hydrated sesquioxide of chromium produced by calcining a mixture of boric acid and potassium bichromate. Valued by artists for the purity and transparency of its bluish green; blending with other colors.

Cobalt Green (Rinmann's green, vert de cobalt, vert de zinc, Kobaltgrün).—Produced by combining by heat oxides of zinc and cobalt. A beautiful green, permanent in oil and water-color.

Emerald Green (cupric aceto arsenate, Schweinfurt green, vert Paul Veronese).—More opaque and brighter than Scheele's green, but also very poisonous. Produced from verdigris and white arsenic. Forbidden for household purposes.

Scheele's Green (cupric arsenite, Swedish green, Mittis green).—Arsenite of copper. Too poisonous for use.

Malachite Green (green verditer, green bice, mountain green, green carbonate of copper, vert de montagne, Berggrün).—A ground copper mineral found on most continents, but Russian preferred for its color.

Verdigris (basic copper acetate, vert-de-gris, verdet de Montpellier Grünspan).—An ancient pigment, but has tendency to darken. Is now preserved from alteration by copal varnish or hard paraffin.

BLUES.

Ultramarine (lapis lazuli, Lasursteinblau, outremer, bleu d'azur).—Genuine is very costly, being produced by heating selected pieces of lapis lazuli, then immersing in cold water or

vinegar; it is then washed, dried and carefully ground and purified. Nearly transparent in water or oil-color and permanent.

Artificial Ultramarine (new blue, French blue, permanent blue, aniline blue, Guimet's blue).—Analyzes same as above natural product, but is produced from kaolin (china clay), silica, sodium sulphate, sodium carbonate, sulphur, charcoal and resin.

Cobalt Blue (cobalt, bleu de Thenard, Kobaltblau).—Three pigments so designated: (1) A combination of alumina and cobalt oxide. (2) Leithner's or Thenard's blue, a cobalt phosphate with aluminum base. (3) Aluminous cobalt arseniate. All permanent except to influence of ammonium sulphide.

Coeruleum (coelin, cerulean blue, bleu celeste, Coelinblau).—Produced by precipitating potassium stannate with cobalt chloride, washing precipitate, mixing with pure silica and heating. Rather greenish blue. Permanent.

Prussian Blue (Turnbull's blue, Antwerp blue, Berlin blue, prussiate of iron, Chinese blue, Saxon blue, bleu de Berlin, Pariserblau).—These include three varieties: (1) Soluble Prussian blue, potassio-ferrio ferrocyanide. Less stable than the others. (2) Insoluble Prussian blue, produced by oxidizing Turnbull's blue with nitric acid, is more permanent than the first. (3) Turnbull's blue, or Gmelin's blue, can be produced by precipitating a ferricyanic acid solution with ferrous sulphate solution. A good color but not as pure as the second, and fades quicker. The common commercial Prussian blue contains proportions of all the above.

Cyanine (Leitch's blue).—A mixture of cobalt blue with Prussian blue.

Indigo.—Derived from the *Indigofera tinctoria*, a leguminous shrub. In the plants the coloring matter is a colorless glucoside which, in combining with water, splits up into a sugar and indigo. Not fast to light as oil or water-color, but is more durable preserved in gum copal. Its high cost forces its being substituted by ultramarine or Prussian blue.

Smalt (royal blue, Dumont's blue, zaffre, bleu de smalte).—Combination of cobalt with potassium silicate. The dark glass is fused, subjected to cold water, then ground fine and washed. Moisture and carbonic acid in the air attack it.

BROWNS.

Raw Umber (Levant umber, terre d'ombre, umbra, Kölnischeerde, terra ombra).—Best comes from Cyprus. Differs from the ochres in having a good proportion of the higher oxides of manganese and less water. The mineral is ground, washed, dried. When heated to acquire a reddish hue it is termed *burnt umber*, the ferric hydrate becoming red ferric oxide.

Burnt Umber. See above.

Raw Sienna (terre de Sienne, Sienaerde, terra di Siena).—Obtained from Tuscany and the Hartz Mountains. A browner variety of yellow ochre with large proportion of ferric hydrate. Used in oil, water and fresco colors. Fades yellower with time.

Burnt Sienna.—Produced by roasting raw sienna, which gives it a warm reddish brown tone, exceptionally translucent. Permanent.

Vandyke Brown.—Three different pigments sell under this name: (1) Calcined brown ochres. (2) A dark variety of colcothar. (3)

A brown earth containing much organic (bituminous) matter and oxide of iron with hydrate. The two first are permanent, the last not.

Cappagh Brown (euchrome, mineral brown).—An earth extracted from the Cappagh Mine in Ireland. It is more reddish than raw umber and contains ferric hydrate and ferric oxide with manganese. Produces a good oil color but permanence is doubted.

Bistre (bister, Braunerlack, Russbraun).—Produced from the tarry soots of certain burnt woods, especially beech. Not used in oils. Fades, by oxidization, in light.

Asphaltum (bitumen, mineral pitch, Antwerp brown, mummy, asphalt brown).—Made from the well-known mineral. (See ASPHALT). Those varieties most free from the paraffin hydrocarbons are preferred for pigments. It is ground in oil or turpentine. They have a tendency to injure contiguous pigments and are not used greatly by artists. The Egyptian mummy submitted to heat, then ground (including the bones) is declared to make a better palette color than asphalt alone.

Prussian Brown.—In the commercial product the soluble potash salt has detrimental effects and should not be used as a pigment till it is purified from it.

Sepia.—The dark-brown pigment obtained from the ink-bag of the cuttlefish. It is prepared by solution in soda or ammonia, then strained and precipitated by neutralizing the alkali with hydrochloric acid. It is then washed and dried. It is not light-fast and is not used in oil.

BLACKS.

Indian Ink (Chinese ink, Japanese ink, encre de Chine, chinesische Tusche).—This consists mainly of lamp-black, produced from oil or pine-wood, combined with gelatine and scented with musk, camphor, cloves or rosewater. The oil used is sesame, Cannabis sativa or Dryandria cordata. The soot is combined with size made from fish glue and parchment. The paste, made into sticks, is subjected to hammer-blows, and, after being shaped as desired, is very slowly dried. It cannot be used in oil but is a first-class water-color. The good grades are permanent.

Lamp Black (noir de lampe, noir de fumée, noir d'houille, Russ).—Soot created from imperfect combustion of resin, oils or fats, paraffin, coal tar oils, or even coal oil, caused by insufficient air supply. The extreme fineness of the microscopical particles renders it exceedingly smooth. It is a gray black and permanent.

Charcoal Black (blue black, vine black, Frankfort black, noir de vigne).—Charcoal produced from non-resinous woods coarsely ground, washed to release soluble mineral matter. Being hygroscopic, it must be thoroughly dried if ground in oil. That gained from willow, maple and bass have been used successfully as a pigment, but nutshells (cocoanut especially) produce the best. If carefully washed and properly carbonized it is permanent. The German pigment is made chiefly from charred grape-vines.

Ivory Black (noir d'ivoire, Elfenbeinschwartz).—Made from charred ivory waste. Permanent.

Graphite.—The so-called black-lead or plum-bago used for pencils and stove polish is also utilized as a pigment, but it is usually mixed

with a heavy base, such as silica. It has many defects. Its chief use at present is as a lubricant.

Mineral Black.—Generally a finely ground heavy black slate, but it needs mixing with carbon and lampblack to give it depth. As its grinding quickly ruins the mills it is not favored by paint manufacturers.

Coal.—Both anthracite and bituminous coal finely ground have been used as pigment.

With the above knowledge of the constitution of the various pigments we see they can be classified as *mineral* and *organic*. Of the first we have the native ores such as ochre, terre verte, ultramarine; artificially prepared are aureolin, cobalt blue, viridian, etc. Of *organic* we have (animal) Indian yellow, carmine, sepia, etc.; of vegetable origin we have gamboge, indigo; artificially produced are Prussian blue, etc.

Mixed Paints.—Until quite recent years the market supplied only dry ground pigments or the same ground in oil. And, when the paint manufacturers attempted to produce and sell a "ready-mixed" paint, ready for the painter's brush, to the house painter and decorator they had a hard task before them. The difficulty in manufacture lay in necessarily overcoming the tendency of pigments ground in oil and supplied with the correct amount of *driers* and *vehicle* from "settling" to the bottom of the package, of *separating* according to the different specific gravities of the elements combined, or even of *hardening*. The successful solution of the problem is due to Americans (generally claimed by New Englanders) and is due to the discovery that the conditions are fulfilled practically by intermixing a solution of silicate of soda ("water glass") with the linseed oil paint.

Zinc oxide next displaced the silicate of soda as it holds up white lead well. To retain the natural moisture, water (not over 4 per cent) is used frequently.

Inert Fillers or Extenders.—Nearly all mixed paints contain proportions of inert matter used to increase their bulk, a condition brought about, largely of necessity. Some pigments in their unmodified form are too heavy for practical use alone, such as white lead. Others are too light or bulky, as lampblack, graphite, etc. Some, again, are too powerful of tone and too expensive to be applied to surfaces without reduction. In the commercial use of prepared paints fillers must, therefore, not be considered as adulterants or substitutes. While they may reduce the prime cost of the paint, they often improve the quality and the practicability. Figuring chiefly among these inert fillers are: Barytes, barium sulphate, barium carbonate, several forms of silica, calcium carbonate, white mineral primer, clays (silicate of alumina), kaolin, asbestine, gypsum, charcoal.

Vehicles.—In order that pigments may be applied to a surface thinning liquids must be added which possess binding qualities so that the pigments may be adhesively retained upon the surfaces to which they are applied. Such liquids are called vehicles or carriers. Nearly all oils are waterproof and will shed water but only a few have the property of solidifying into a hard waterproof surface coat and these latter are called fixed oils.

Flax and poppy are the only plant seeds of

importance in the paint industry as producers of fixed oils. Poppy-seed oil is in some respects superior to linseed oil, the fact that the latter is by far the cheaper has made it the well nigh universal oil for use as a pigment vehicle.

Volatile oils are used in painting for rectifying some defects in the fixed oils that are used as binding vehicles in exterior painting and for what is called *flatting* in interior work. Their use enables a painter to put on a heavier coat of pigment with less linseed oil than would be possible with the use of linseed alone since the volatile oils mix intimately with the fixed oils render them more fluid. The principal volatiles in use are spirits of turpentine, or oil of turpentine, naphtha and benzene. A widely used vehicle is *tung* oil, produced from the wood oil tree (*Aleurites Cordata*), made in China. Fish oil obtained from menhaden and refined has been found a good substitute for linseed oil. The tung oils of China and Japan are very good mediums (some declare the best) for waterproof and marine paints. Poppy seed oil is a favored medium for artists' colors. Turpentine is used largely for diluting or dissolving pigments. Benzene (or benzol) is extensively used in the manufacture of ready-mixed paints; acting both as diluent and as liquid dryer; its low cost has no doubt been an incentive.

Driers.—While linseed oil dries by oxidation in the air, it is frequently necessary to accelerate its action by the addition of certain siccatifs. The desired function of a drier in oil paint is to accelerate the absorption of oxygen to create a film of dry, hard, insoluble substance on the outer surface. There are two classes of driers: resin driers and oil driers. Oil driers are produced by heating linseed oil combined with a salt of oxide of lead and manganese to from 500° to 600° F. This is reduced with benzene or turpentine or both. The "resin" driers, known also as "Japan driers" are composed of metallic salts or bases fused with resin and linseed oil, then reduced with benzene or turpentine. They dry quickly as a varnish. The latter kind of driers has defects not contained in the oil driers.

Paint Statistics.—The census of manufactures for 1919 states the following: With 601 paint manufacturing establishments having a combined capital of \$177,314,815, employing 17,485 wage-earners, the product amounted to \$256,714,379. Pigments were produced to the value of \$72,457,266, including zinc oxide, \$24,082,299; lithopone, \$9,757,599; white lead, \$6,318,504; lead oxides, \$12,748,344; chrome yellow, orange or green, \$2,081,440; fine colors, not elsewhere specified, \$2,384,054; iron buff or other earth colors, \$3,778,942; Prussian blue, \$645,179; moist pulp colors, \$3,262,284. Paints in oil were produced to the value of \$168,525,448.

CLEMENT W. COUMBE.

PAINT, Luminous, a phosphorescent substance used as a coating for surfaces. The phenomenon of phosphorescence, which gives to luminous paint its distinctive character, has nothing to do with phosphorus, whose luminosity is due to slow oxidation. The first discovery of a substance emitting light without oxidation belongs to the early part of the 17th century, when sulphide of barium (Bologna stone) and chloride of calcium (Homberg's phosphorus) were discovered. Sulphide of calcium dates from 1768; sulphide of strontium is the latest discovery in this kind. Any of these substances, if enclosed in a sealed glass tube and exposed to sunlight, and then carried into a dark room, appears at first brilliantly luminous and long afterward like a hot body cooling. Practical application has been made of the property in the production of luminous paint, the above compounds being ground and mixed with a vehicle, as in ordinary paint and laid on the surface that is to be made luminous. A modern improvement of this method is the admixture of a small amount of radioactive matter, which makes the paint independent of exposure to daylight. Luminous paint is used chiefly for the dials of watches or compasses for use at night.

PAINTED DESERT. This name is applied to the wide area of plateaus and low mesas extending along the east side of the valley of the Little Colorado in northern central Arizona. To the north it extends along the top of the east wall of Marble Canyon of the Colorado River; to the south it ends near the Santa Fé Railroad which crosses it from Holbrook to Winslow. Along the east side rise the Echo Cliffs to the north and farther south the high plateaus and buttes of the Hopi Indian pueblos. Thus defined its length is about 100 miles and width 15 to 20 miles. Most of it lies at an altitude of nearly 5,000 feet. The climate is arid with annual rainfall averaging about six inches and consequently the vegetation is scant. Vast areas of the rocks are bare or nearly so. These rocks which are upper Permian and Triassic in age lie nearly level in a succession of low steps rising to the east. They present a great variety of colors, red, pink, chocolate, purple, lavender, pale green and gray, which suggested the name Painted Desert applied by Ives and Newberry in 1858. Consult Gregor, H. E., *The Navajo County*, U. S. Geol. Survey, Water Supply Paper 380, and Professional Paper 93; Darton, N. H., *Reconnaissance of Western New Mexico and part of Arizona*, U. S. Geol. Survey, Bull. 365, Darton, N. H., *Guide Book of Santa Fé Railroad*, U. S. Geol.

Survey Bull. 613; James, G. W., 'Indians of Painted Desert Region' (Boston 1903).

PAINTED QUAIL. See QUAIL.

PAINTED TERRAPIN or TORTOISE. See TURTLE.

PAINTING, in the fullest meaning of the word, signifies the application of color to any surface, for the purpose of making it more attractive to the eye, or as a preservative of the substance painted, but in this article the word is restricted to the art of painting, that is, the art of representing objects, real or imaginary, on a flat or nearly flat surface by the use of designs in line and color. Leaving out of account the designs of bison and reindeer made by prehistoric man in the caves of Europe, the origin of this art, like that of several others known to civilization, is lost in the mists of those prehistoric ages on the banks of the Nile which the researches of modern Egyptologists have pushed back, apparently, to the distance of 80 centuries. Some few traces of it among the unknown autochthonous races who preceded the long lines of the dynasties of Upper and Lower Egypt have been but recently assigned to their proper sources; the art of the dynasties of the Pharaohs and the Ptolemies, notwithstanding their duration by centuries, presents certain striking characteristics which distinguish it from all others. It was strictly a conventional and symbolic art, largely an official art, devoted to the service of the monarch and of religion and within these limits, a decorative art. Sculpture was subservient to architecture and painting—except on the walls of the tombs and in the papyri—to sculpture. Our knowledge of painting is derived from the very numerous examples preserved on the walls of the temples and the tombs, on the mummy cases and the sarcophagi, on the funeral tablets and the illuminations and vignettes on papyrus and linen. The conventions in which the art remained bound—with but few exceptions—were established in the earliest ages; they embraced all design, religious and secular, requiring that human figures and those of animals should be represented in profile, defined by an outline and in flat color; for landscape and architecture there was adopted a curious and ingenious combination of drawing, both in ground plan and in elevation, to express the scene in the simplest and clearest manner possible. The background was left blank, or filled with a flat tint; the required lucidity and directness of expression forbade the use of linear or aerial perspective, or any attempt at modeling or variation of the conventional local color. On the inner and outer walls of the temples the outlines were incised, sometimes very deeply,—the figure within these outlines frequently rounded down to the bottom of this incised outline; on the walls of the tombs the painter replaced this outline with one made by his brush. He worked directly on a coat of white stucco, applied over a rough-cast to conceal the joints and the roughness of the masonry wall; of colors—derived mostly from mineral sources—he had, at the most flourishing period of the art, as many as 18 or 20, as we know from wooden palettes of the 18th dynasty, which have been found. These colors were mixed with water and gum tragacanth, possibly with honey; some

mummy cases of the later dynasties have been painted in encaustic and in some cases the eyes and eyebrows of the mummy masks are in enamel. These colors have retained their brilliancy to a remarkable degree through the ages; very few of the paintings are cracked. The artist worked with brushes of reeds or rushes, the ends of which were soaked in water until their fibres separated and they were adapted to the finest and most delicate work. In the papyri—as in the many hundred copies of the Book of the Dead extant—the illustrations stretch along the top of the page, like head-pieces, or are inserted as vignettes, or initials, or full-page pictures. In many cases they are merely outline sketches in black or red. In general, figures of men are colored a dull red and those of women a light yellow, the gods and the genii of the dead may be of positive greens and blues and the animals are frequently spotted. The colors are always pleasing and harmonious and on the largest wall spaces a comprehensive and well sustained color-scheme is frequently found, designed and carried out with true artistic skill. On the outer walls, exposed to full sunlight and in the deepest recesses of the tombs, the colors are most vivid; in the intermediate chambers of the tombs they are more quiet and discreet, to suit the tempered light. See EGYPT.

Greek and Roman Painting.—In the middle of the 6th century before Christ, Greek painting was technically no farther advanced than that of Egypt or Assyria. Greek writers speak with the same enthusiasm of the works of their great painters as of those of their sculptors, but it is only by these descriptions and by some supposed copies and adaptations in the work of the craftsmen, mural painters and mosaicists, of the decline of the art under the Roman domination, that we can form some definite conception of these masterpieces. It is noticeable that the rhetoricians are especially impressed by the ability of the painters to represent objects so naturally as to mystify the spectator. The development of the art through its various phases can be fairly well traced in the wall paintings discovered in Etruscan tombs; it practically embraced all subjects, mythology, history, scenes from daily life, landscape, marines, portraits, animals, tragic and satirical representations, still-life, ornament and decoration and miniatures. Composition, order, linear and aerial perspective, chiaroscuro, a knowledge of the human figure extending to foreshortening, action, expression by gesture and by countenance, all were included. The color work was even extended to the tinting or painting of statues (though there seems to be no proof that the Greeks colored the nude parts of their marble statues) and to the moldings, triglyphs and other ornaments of their architecture. Praxiteles (q.v.) when asked which of his works in marble he valued the most, replied: "Those on which Nikias (the painter) has set his mark."

In Pompeii, the painted portions of the temples are always finished in stucco or plaster. Portrait painting was apparently more in favor among the Romans than among the Greeks. The long series of painted vases—from the earliest examples of the "Pelagic" or pre-Homeric period down to the disappearance of the art about 65 B.C.—was but one of the

features of this comprehensive school of painting. The only examples of easel pictures which have been preserved are a few small paintings on marble and slate, found in Herculaneum and in Etruscan tombs.

Apelles introduced the use of a glaze or varnish over the completed tempera painting. In the latter, the colors were tempered with a glue, a gum, honey, white of an egg, juice of the fig, milk, or other glutinous substance, soluble in water, that served to bind them; or with wax or some resin, when these materials had been rendered by any means vehicles that could be worked in water. In tempera painting colors were applied to the dry wall; in fresco (See FRESKO), to the wall while the plaster was still wet. Both methods are found in Pompeii; the backgrounds always in fresco and generally, the architectural framing and ornaments; the small figure panels in the centre are generally painted in tempera on the fresco background. In fresco, no colors except earths were used, and these were protected by an encaustic varnish, which also served to give them more brilliancy. Encaustic painting was used only for pictures on tablets or on canvas; in this process naphtha, or spirits of turpentine, or any volatile, ethereal oil that will evaporate, leaving the wax colors firmly fixed, can be used as menstrua to liquefy the wax. In the usual method, when the colored sticks of wax and resin have been melted over a fire the colors are applied broadly with a brush and then blended by means of a metallic instrument, a spatula or cestrum (generic name *cauterium*), at times used very hot. The same instrument is used to finish the painting by taking, while still hot, cold wax colors and blending and grading them on the first painting. The colored sticks of wax and resin, softened by the addition of an oil, may be applied from a hot palette with a brush and then melted and modeled with the cestrum. The same sticks, softened by the addition of an oil, may be used directly, like crayons of pastel; or, when dissolved in an essential or volatile oil, applied with a brush; but these two methods, not involving the use of heat, are not, strictly speaking, encaustic painting. In all cases, the ancients prepared their walls very carefully before painting, the final surface receiving a firmness and consistency almost equal to that of marble. Their colors were almost exclusively mineral, the only animal substance known being the slimy matter of the *Murex* (q.v.), mixed with chalk. This purple is unknown to the modern palette.

Byzantine and Early Mediæval.—The influence of ancient art on that of the early Christians was long in disappearing—notwithstanding the widely divergent tendencies of the new religion. Inheriting the Jewish aversion to idolatry and to works of material imagery, the Fathers of the Church declaimed against all artists—Tertullian denounced them as persons of iniquitous occupations. The paintings and decorations in the Roman catacombs—rediscovered at the end of the 16th century—especially those in the earliest cemeteries, bear a great resemblance to the ancient wall paintings. Orpheus playing on his pipes reappears as the youthful and beardless Christ surrounded by his sheep, and Hermes Kriophoros, carrying a ram on his shoulders, as the Good Shepherd. The

bearded type of the Saviour, with which we are familiar, was not generally adopted till later, in the earliest mosaics. As the Church increased in numbers and power the primitive prejudices disappeared, but early Christian painting shared in the general decline of all the contemporary art of the empire. Occasional efforts were made by the emperors to check this decadence, by Constantine and by Valentinian, Valens and Gratian in the 4th century; and in the 5th by Theodoric at Ravenna, the capital of the Ostrogothic kingdom in Italy. The first mention of church painting is found in a canon of the council held at Illiberio (Granada), Spain, about 305 A.D.; but the mediæval wall paintings have nearly all disappeared—very largely by conflagrations. Our insufficient knowledge of the early mediæval painting is principally derived from the mosaics, the most important being at Ravenna and Rome, and from the miniatures and the illuminated manuscripts. In Byzantium, the mosaic wall decorations were not confined to the churches but were also employed to celebrate the deeds and the power of the monarchy, as in the Chalkê, the great state hall of Justinian's palace. With the establishment of the Lombards in Italy, the ideals, the freedom and spirituality of both the Church and its art, fell into even stricter bondage. The subject of the Crucifixion first appears in painting in the latter part of the 6th century, the figure of the Saviour frequently clad in a long purple robe and sometimes wearing a regal crown. The classical period of early Christian art came to a close with the outbreak of the Iconoclastic schism, in the beginning of the 8th century.

The mediæval style was formed by the gradual union of these classic traditions with the hereditary art of the Western barbarians conquered by the empire or who overran it. Each of these races contributed an individual note—the Irish monks excelled in illuminating manuscripts, their art being continued by the Anglo-Saxons; under Charlemagne mural painting, both sacred and profane, was greatly in favor, though nothing now remains save miniatures; but these primitive impulses did not extend south of the Alps until the Romanesque period, ending in the 13th century. The first indications of Gothic art appear in the miniatures toward the close of this period—in the angular and broken folds of the draperies, indicating that tendency which was to "govern the human sense of form in all its modes of expression, down to handwriting."

Later Mediæval-Gothic.—It was in France that the so-called Gothic architecture took its origin; and there, too, that the other arts took the lead in Europe, in the middle of the 12th century. Painting gradually escaped from the domination of the priestly order; the painters became specialists, working exclusively at mural paintings, particularly so in the northern countries. Hence, a certain growth of individuality of conception, a tendency toward subtlety and mysticism, an attempt at realism, including study from nature—the whole, as yet, much hampered by tradition. After the middle of the 14th century there appeared very definite signs of an appreciation of the full capacities of the art of painting and serious attempts to realize them. In this art, including miniature painting in books, France took the lead, as she had done in architecture. The development of

Gothic architecture, as it diminished the spaces for wall paintings, greatly increased that of the windows, and thus gave a great impetus to the noble art of glass painting. In the 14th century, distinct schools of painting begin to appear, as, in Germany, those of Prague, of Cologne, of Westphalia, etc., and even the names of individual artists become known; the panel paintings of the French and the Flemings bear a general resemblance to those of the Lower Rhine; but in Italy the art, both in conceptions and in technical methods, followed distinct national lines—preparing the way for the Renaissance. Foremost among these precursors were the Tuscans, Niccolò Pisano (q.v.), the sculptor, and Giovanni Cimabue (q.v.), the painter. The first great epoch in modern painting is considered to have been that signalized by the mature works of Giotto di Bondone (q.v.) (1276-1336), a pupil of Cimabue, who was acclaimed by his contemporaries as the greatest genius in the arts of Italy. To their astonished eyes, Giotto's power of presenting objects naturally was so great that "the thing itself" was reproduced. With this he combined a great command of the arrangement and execution of monumental mural painting and a freedom from the traditions both of the Byzantine manner and the Northern Gothic, while reproducing in his works many of the decorative ideas of the ancients. Chief among his followers was Andrea di Cione, called L'Arcagnuolo, or, in the contracted form, Orcagna. The painters of the school of Sienna ranked almost in importance with those of Florence; and in the Campo Santo of Pisa are still preserved some of the greatest monuments of fresco paintings, executed by various artists of this closing period of the Middle Ages.

China and Japan.—The technique of the art of painting in China and Japan is founded primarily on the caligraphic dexterity which was the chief ideal of the older Chinese painters and their Japanese followers, and which is still held in high honor. The ancient art of handwriting was based upon a system of representing or symbolizing the thing indicated, and both it and the art of painting were fettered by traditions that were as binding as those of Egyptian art. Linear design has remained the important element even in painting, the outline being always retained. As an art primarily decorative and suggestive, and not realistic, its fundamental principles differ widely from those of all the European schools. The Japanese themselves compare their art of painting—which they consider the richest and most important, the most intimate expression of the national character—to "sketching." (*La peinture japonaise a la caractère d'une esquisse*, says the official work published by the Japanese Imperial Commission at the Exposition Universelle of Paris, 1900). As a *sketch*, or, rather, as a work in which only the essentials are retained—appealing to more artistic and more intelligent taste than the finished realistic picture—these paintings dispense with careful definition, with chiaroscuro and perspective, qualities neglected by both the Chinese and Japanese masters in their search for idealistic design and decorative feeling. The care bestowed upon the line leads to a very skilful characterization and suggestiveness in design—marred by the limitations and conventions of both national arts; the generally tem-

pered and restricted color scheme permits of the most subtle and beautiful tones and of a very artistic rendering of aerial perspective in the landscapes, especially in the Japanese. The painter does not hesitate to leave his canvas or his paper untouched in spots so as to concentrate on the principal motif; he is in search of an abstract beauty, not of that of the individual—in accord with the Buddhist principle of the social development rather than of that of the individual. This is peculiarly true of the Butsu-yé, or picture of the true Buddhist school, which is distinguished from the works of the secular artists by certain distinctive qualities. In China, notwithstanding the number of epochs which the art of painting has traversed and the varying influences to which it has been subjected, it has retained throughout a general unity of principles. The Japanese claim that in deriving their art from the Koreans, the Chinese and the Hindus, they had bettered their instructions and given their own style to the art—a greater charm and subtlety of line, a greater delicacy and beauty of tone in the color. Both nations refer the origin of their art to a legendary era, the Japanese claiming 13 centuries of duration and the Chinese historians ascribing the invention of painting to Che-hoang, minister of the Emperor Hoang-ti, in the 27th century before Christ, contemporary with the introduction of writing by Tsang-hie—these two personages considered by some authorities to have been identical. No satisfactory record of an individual painter, however, appears before the 3d century A.D., nearly 200 years after the introduction of Buddhist pictures and images from India. According to an ancient Japanese writing, the history of pictorial art began in that country in the reign of the Emperor Yuriaku (457-479 A.D.), introduced by a Chinese painter of royal descent, Nanriu or Shinki. It is probable that Japanese art took its real birth at the period of the introduction of Buddhism in the middle of the 6th century.

Persia and India.—It was from China that Persia originally derived the arts of architecture, painting and ceramics; for the second of these, the general principles and the technical methods, even to the vellum upon which the paintings were executed, were Chinese. Later, many of the elements of the art were adopted from that of the Arabian Caliphate, an art which had been born in Egypt and developed in Syria. Under the dynasties of the successors of Genghis Khan (1199-1335 A.D.) painting in Persia assumed definite forms and characteristics; indeed it is asserted to have been borrowed from Turanian, Dravidian, Greek, Sassanian, Mongol and European sources. During the Mohammedan domination its influence was extended to India, where it succeeded the native traditions. The art of the two countries under the Mongol emperors was practically the same; in both the ancient mural paintings having almost completely disappeared, it is preserved only in the miniatures. Modern Hindu painting and sculpture are both in lamentable decadence; the former, never having even undertaken to represent nature, is content with traditional and decorative formulas.

For painting of Europe after the close of the Mediæval epoch, see RENAISSANCE PAINTING; POST-RENAISSANCE PAINTING.

Author 'Chefs d'Œuvre Expo, Universelle 1889.'

PAINTING, Education in. The education of the painter is to-day altogether different from what it was in the Middle Ages and the Renaissance, and this difference is largely dependent upon a different conception of the social status of the artist. In the mediæval world the painter was a craftsman, like the carpenter or the smith. Often, indeed, he had been trained as a goldsmith before he became a painter. The individual artist might rise to some eminence and consideration, but as an artist he was a member of a mechanical trade which no one would have thought of putting on a level with the learned professions. To-day the painter, the sculptor, the architect, is a professional man, like the lawyer or the physician, and his education is planned, as nearly as possible, on the lines of theirs. As long as the artist was considered a tradesman he was educated like a tradesman; that is, by apprenticeship to a master of the craft. In a modified form this apprenticeship system was in force as late as the 18th century, but its character can best be understood by considering it as it was practised in the 15th.

In the 15th century, then, the master painter kept a shop, a bottega, which differed in no essential particular from the shop of any other tradesman, and his business was to supply anything that was wanted in the way of painting, from the ornamentation of a chest or the painting of a sign to the production of an altarpiece or the frescoing of a palace wall. He maintained a force of journeymen and apprentices, and it was no more expected that he should produce with his own hands everything which left his shop than it was expected that

the master joiner should plane every board or the master mason lay every stone. To such a master a boy who showed any disposition toward art was bound out, at the age of 12 or 13, for a term of years. He was to give his services in any capacity in which they were available and a sum of money was paid the master, who, in return for this premium and service, engaged himself to teach the boy his trade. The apprentices swept out the shop, ran errands, waited on customers, ground colors, prepared canvases and panels, pricked cartoons and pounced them upon the wall, set the palette and cleaned the brushes of the master. At odd times they copied the master's studies, and always they watched his methods and learned how he did things and by what succession of processes a picture was produced. At the end of his term of apprenticeship the boy had learned enough to be useful and was worth a wage. He became a journeyman and was free to stay with his master or to engage himself to another. At this stage of his evolution he was intrusted with more important work, designed borders and gilded halos, painted backgrounds or draperies from the master's studies, made studies himself for the less important parts of pictures, finally painted entire pictures himself under the master's supervision and on the master's account—pictures which were almost indistinguishable from the master's own and were frequently signed by him before delivery to the customer who had ordered them.

If the young painter were unambitious he might remain at this stage all his life. If he were determined to be a master in his turn he probably traveled a little and engaged himself to this or that more celebrated master that he might study other methods than those he had learned, pick up other traditions and familiarize himself with the best work that was being done in his art. When he could do what his masters did as well as they did it, and hardly until then, he was ready to observe nature for himself, to allow his own temperament to influence his work, to become, perhaps, a creator and an innovator, and to teach others all that he had been taught and all that he had learned for himself, so that they might begin, as nearly as possible, where he left off.

The typical education of a modern painter is as different from this as possible. He begins his special education later than did the mediæval painter, having spent some years in ordinary schooling, perhaps even in securing a college training. He may have done a little desultory drawing during this time, but about the age of 20 or later he decides to become a painter and begins his serious education in art. He begins it not as an apprentice, but as a student; not in a shop, but in a school. If the school is a great state institution or one connected with a university, it will afford lectures on the theory and history of art, to which, likely enough, he will pay little attention. It will be in a great city, where he will be able to visit museums which have gathered together the art of many ages and many countries, and to see exhibitions where almost as many methods of work are exemplified as there are individual exhibitors. Even in default of museums and exhibitions he will infallibly have access to many cheap publications which, by some of the applications of photography, will give him a

fair idea of the results, attained by the art of the past and the present; of its methods he will know nothing. Meanwhile he will be set down before a plaster cast or a living model and bidden to draw. He will be more or less thoroughly grounded in anatomy and perspective and other sciences, above all in the science of aspects, but he will have practically no instruction whatever in his craft. His canvases and colors, like his brushes, he will buy ready made. His master he will see twice a week, for a few minutes, and that master's criticisms will be directed exclusively to the justness of his observation and the truth of his rendering of nature. The master's own work will be carried on in another place, in quiet and in solitude, and the student will know nothing of it except, now and then, to see the completed picture. The more intelligent and conscientious the master the less likely he will be to attempt real technical instruction, for he will feel that his own methods are tentative, suited to himself alone, and of doubtful validity or permanence, while he will be hampered by our modern respect for individuality and the fear of destroying something more precious than anything he can supply.

After three to five years' work on this system our student will be able to draw with fair accuracy anything set before him, to distinguish its values, even to copy its color with some approximation to success. On the other hand he will have exercised little either his invention or his memory, will know nothing of ornament and little of design, and will be entirely in the dark as to what he wishes to do with his acquired science, while he will have had no practical experience of the thousand and one processes that go to the production of a picture. Likely enough he will never have made a tracing or squared up a sketch; almost certainly he will never have arranged a drapery; quite certainly he will, no more than his master, know anything of the proper management of oil colors, of the use of vehicles or of the composition and permanence of pigments. For a time he will try to do outside the school what he has always done in it, and will be surprised that no one cares for the result. Then it will perhaps dawn upon him that he has learned a science but not an art, he will flounder and experiment, and, if he is a man of force and originality, he will invent an art of his own and methods that will somehow serve his needs. If he is of a cool and logical mind he will recognize that his training was vastly better than none and will, in default of a better, recommend it to others or help to give it to them. If he is of a warm and emotional temper he will condemn it as useless or worse and tell those who consult him to get along without it.

It is obvious that the results of these two educations must differ as greatly as the conditions which produced them. The modern painter may readily be a man of broader culture and wider outlook than the painter of the Renaissance; with anything like the same original force he will probably be a more personal and individual artist; he will certainly know a great deal about the aspects of nature that the Renaissance painter never dreamed of. Just as surely he will be the inferior of the Renaissance painter, both as designer and as crafts-

man, will rarely attain complete mastery of his tools and will try to substitute the charm of his personal sentiment and his individual view of nature for that assured rightness which comes of an accepted body of traditions and the possession of tried methods. What modern art has gained in variety and in the perception of new truths it has lost in weight and coherence. Each artist works in his own way for the attainment of self-expression and does little toward the building up of a great school.

It is easier to see the weakness of modern education in painting than to devise a remedy, and those who are most opposed to the modern academic system seldom suggest anything to take its place. There are many reasons why the old apprenticeship system could hardly be revived. There are such multitudes of students to-day that it would be impossible to find masters for them, and our masters have, in general, nothing for apprentices to do. They are no longer at the head of great workshops, turning out a multiplicity of diverse products. Each is engaged in a more or less narrow specialty, producing work which is valuable only as it possesses his personal quality and exhibits his personal touch, and his patrons would resent the intrusion of any hand but his own as little less than commercial dishonesty. The modern student also knows too much of the art of all times and countries to choose a single master and docilely follow his teaching. It is doubtful if modern conditions have not rendered forever impossible anything like a local school of painting.

The conditions of mural painting do, indeed, entail something like the old apprenticeship system, and in the growing demand for the decoration of public and private buildings there is a hope for the revival of older methods of education. It is recognized that a decorative painter may properly have a corps of assistants, and while these assistants are not likely to be mere beginners, but will already have had an academic training, they are enabled to supplement it with the practical instruction of a master in the methods of creating a work of art.

How far a similar instruction can be grafted on our academic system is the problem that should most seriously occupy the directors of our schools of art. The rigid discipline in drawing and painting from nature need not be relaxed—in its way it is admirable and should be strengthened rather than weakened—but it should be pointed out that the ability to imitate form and color is a tool, not an end, and that the creation of a work of art is something different from the production of a life-study.

To this end the student should be thoroughly grounded in ornament, both as a training of taste and an exercise in design, and the study of nature should be, as far as possible, subordinated to artistic creation, the structure and appearance of things being learned as they are required for expression. In this way they would be learned both more permanently and more easily. The student's memory and imagination would be educated as well as his eye and his hand, and in the creation of an actual work of art, under the guidance of his master, if that work of art were no more than a painted border or bit of scrollwork, the importance of sound technical methods would be

readily appreciated. Such students as had any real talent for painting would be vastly better trained than most of our painters now are, while the others would have a chance to become competent workmen in some of the minor decorative arts instead of adding to the world's too great stock of bad pictures.

And while it must be insisted upon that the education of eye and hand can hardly begin too early, if technical mastery is to be attained, and that we must be willing to sacrifice something of the education of a gentleman to the education of a painter, it would be well if some tincture of mathematics, of history and of letters could be given to take the place of that college training which must of necessity be foregone. See also ARCHITECTURE, EDUCATION IN; SCULPTURE, EDUCATION IN.

KENYON COX.

PAINTING, Technique of. Painting as one of the fine arts may be defined as the application of color on a surface for decorative purpose; or the representation of natural or imagined objects by means of colors applied on a surface in such a manner as to produce an illusion of reality in form, light and shade and color. It is to the last form of painting, known as pictorial representation, that we shall chiefly devote our attention in this article.

Painting may be divided into (1) monochromatic painting, including drawing in pencil, charcoal, ink and crayon, etc. (see ART DRAWING), in which class, pictures of objects are rendered in various shades of one color; and (2) polychromatic painting in which the artist seeks to express not only the form, light and shade, but also the full charm of color displayed by objects. According to the subject represented, painting may be grouped as follows: (1) historical, including religious and mythological works; (2) portraiture; (3) genre—the representation of domestic life; (4) animal; (5) still-life—pictures of fruit, flowers, pottery and other inanimate objects; (6) landscape and seascape.

To be able to express himself fully in his work, the painter must know anatomy in figure and animal painting; aerial and linear perspective in landscape and marine painting; and the principles of pictorial composition (see ART DRAWING) in all the forms of pictorial representation. He must also have a good working knowledge of the theory of color, the chemistry of paints, oils and varnishes, and the special technique of the particular form of painting he is pursuing. The subject of painting, therefore, will be treated here in two sections. In the first part, the technique of painting of which there are several kinds will be described; in the second, the history of the origin and development of the various schools of painting in general will be told.

The technique of painting refers to the artist's manipulation of his purely material equipment in his effort to reveal to his fellow beings his impressions of the varied beauties of nature in form, color and perspective. It includes the preparation of the foundation, or ground upon which the painting is executed, and the proper use of the pigments, vehicles and preservative agents. To render the coloring substance applicable, it is mixed with many different kinds of binding materials or media, giving rise to as many different processes of paint-

ing, viz., encaustic, tempera, fresco-buono, fresco-secco, spirit fresco, stereochromy, oil, pastel and water-color. The particular technique of each will now be described.

Encaustic Painting.—Encaustic (Gk. *ἐγκαυστικός*, *enkaustikos*, burnt in) is a process of painting used by the ancients and revived in modern times in which the colors are mixed with wax and resin and liquefied by heat. It was peculiarly an ancient Greek method of pictorial expression, as in Greece the process reached its highest development. Several mummy masks have been found that prove the knowledge of encaustic painting by the Egyptians, but it was not adopted by them till after the Macedonian conquest. The Greeks used it not only in flat tints to cover plain surfaces or sculptured ornament, but also to model the subtle human form. The British Museum, the Louvre, and the Metropolitan Museum of Art, New York, possess good examples of Greek encaustic portraits (chiefly from Fayum, Egypt) together with the cestra, braziers and other implements used in the process. Many of the mural paintings in Pompeii were also executed in this medium. In modern times the secret of the process was largely lost despite the many attempts of the savants to solve the riddle, until 1884 when MM. Cros and Henry published in Paris their now famous monograph entitled 'L'Encaustique et les autres procédés de la peinture chez les anciens, historique et technique,' in which they fully restore the encaustic process. They describe four varieties, based upon a thorough study of existing examples of and writings on encaustic painting. These are as follows:

(1) Colored sticks of wax and resin are melted over a heater either in separate cups or on a metallic palette with depressions for the colors. The tones are then applied hot on the surface to be painted, with a brush and blended with a hot cestrum. To give gradations to the modeling, the intermediate tones are applied with a hot cestrum from the cold wax colors on the cooled palette.

(2) Similar to the first process but with the addition of an oil to facilitate the work.

(3) Cold applications of the preceding mixture conveyed to the surface to be painted, and modeled with cold cestra.

(4) Cold brush-painting with colors of wax and resin dissolved in an essential and volatile oil such as spirits of turpentine. Strictly speaking, the last two processes are not encaustic, because there is no "burning in."

In the last century many mural paintings have been produced in a wax medium that represents but a variation of the fourth process described above. Pictures in this manner were executed by Hippolyte Flandrin in Saint Vincent de Paul and Saint Germain des Prés in Paris; by Andreas Müller in the National Gallery, Berlin; and by Fernbach in the Hohenstauffer Hall of the Royal Palace in Munich. Wax painting for mural decoration is popular with our contemporary mural painters because of its several advantages. These are: (1) its durability; (2) its matt surface and atmospheric tones; (3) its impasto, equaling that of oils, and (4) its quick-drying qualities.

The authorities on the subject are Cros and Henry 'L'Encaustique et les autres procédés de la peinture chez les anciens' (Paris 1884);

Richter, O., Donner von, 'Über Technisches in der Malerei der Alten' (Munich 1885); Crowninshield, 'Mural Painting' (Boston 1887); Laurie, 'Greek and Roman Methods of Painting' (Cambridge 1910).

Tempera.—The Italian word *tempera* originally meant any fluid vehicle with which coloring matter may be mixed, including oil. At present it is applied in a restricted sense to a form of opaque water-color process in which the binding substance is one of the following: (1) yolk of egg; (2) yolk and white of egg beaten together and diluted with the juice from young shoots of the fig-tree or with vinegar; (3) size, in which there is no egg but a thin glue, as gums arabic and tragacanth, glycerin, honey, milk or pieces of parchment boiled down. The size tempera is considered the best as the coloring matter in yolk of egg tends to make yellows deeper, turns red into orange and blue into green. The solvent for all is water. The brushes used are of sable or camel's hair; and any dry surface as paper, canvas, panel or plaster is favorable.

Tempera paintings are characterized by sharp and clear definition (the rapid drying of the color does not permit any blending); flat, brilliant and atmospheric tones; and matt surface. Their main weakness is that they are very perishable. As the colors are soluble in water they are ruined by contact with moisture either on the surface or from behind. Besides, the paint is liable to peel if applied in more than one coat, or when too much egg or size has been used, and is easily defaced by friction. In fact, to preserve pictures in this medium, it is necessary to coat them with an oil varnish.

A thorough study of the paintings of the ancients—the mummy cases and papyrus scrolls of Egypt, the wall paintings of Babylon, Assyria and India, and the panel and wall decorations of ancient Greece and Italy—reveals the fact that the tempera process was used extensively by them from time immemorial. In Mediterranean Europe it prevailed until the 14th century when it gradually gave way to the growing popularity of fresco. In the north of Europe it was much in vogue for panel pictures until about the year 1400 when the superior oil medium was perfected by Hubert and Jan Van Eyck. At the end of the 15th century tempera completely ceased to be used in all countries. In modern times efforts were made in England, France and Germany to revive it but so far with little success. At present it is mostly used for painting theatrical scenery. Among the existing examples of tempera painting by Renaissance masters may be mentioned the famous 'Portrait of Isotta da Rimini' by Pietro della Francesca in the National Art Gallery in London; the 'Portrait of an Old Man with Red Cap' by Albert Dürer in the Louvre, and the 'Three Graces' from Botticelli's 'Allegory of Spring' at Florence.

Consult Pereira, 'Leitfaden für die Temperamalerei' (Stuttgart 1893); Cennino Cennini, 'Trattato' (Eng. trans. by Mrs. Herringham, London 1899); Friedlein, 'Tempera und Temperatechnik' (Munich 1906).

Fresco Painting.—Fresco is a form of mural painting executed upon wet or fresh plaster. The term is derived from the Italian *al fresco* which means fresh. It is often indis-

criminally applied to all kinds of mural painting from tempera to encaustic. This is improper and unnecessary. In true fresco the colors are not mixed with wax as in encaustic nor with any kind of glue, size or yolk of egg as in tempera; but either with pure water or with water and lime, and applied on the wall while the plaster is still wet.

The technique of *buon-fresco*, as true fresco is sometimes called, to distinguish it from the false is as follows: The wall to receive the fresco is usually of well-dried and uniformly hard brick. A double wall with an air space is the best. To prepare the wall it is necessary to cover it with two kinds of plasterings—the *arriccio* or rough cast, and the *intonaco* or finishing coat. The *arriccio* which is composed of two parts of sand to one of lime is usually less than half an inch thick and is applied in two or three successive coats. Its surface is roughened the better to hold the finishing coat, and is left to dry for a very long time. When thoroughly dry, it is ready to receive the *intonaco* on which the fresco is painted. After saturating the *arriccio* with water, the *intonaco*, which is composed of well-prepared lime and fine sand, is spread in two thin coats, the whole being about one-tenth of an inch thick. A trowel or wooden float is the tool used for spreading the plaster. The *intonaco* is not laid all at once but in parts, according to the space which the artist expects to be able to cover in a single day. When the picture is so small that it can be completed in a day, the outline is transferred directly from a well-prepared cartoon to the *intonaco*. If, however, the picture is large, requiring several days or more in its execution, the cartoon is transferred to the *arriccio* before any of the *intonaco* is laid. The artist indicates the portion he can paint in a day and the mason who is specially trained for the work prepares it with the *intonaco*. When the day's work is done, any of the plaster that has not been painted upon is removed and is beveled at the edges of the finished work. On the following day the mason joins closely another patch of plaster to the edge of the portion painted upon the previous day, and so on.

The cartoon is usually a carefully prepared outline drawing of the subject of the same size as the fresco is to be and is transferred to the wall by *pouncing*. The method of pouncing is as follows: The outlines of the cartoon are pricked with a large pin of wood or bone. Some powdered charcoal is then spread on a piece of soft muslin which is tied up like a bag. The cartoon is attached to the wall and the bag is briskly rubbed over it. On removing the cartoon, an impression of the subject will be found on the wall.

The brushes used in fresco are long and supple and of bristle, marten, sable or otter. The palette is generally made of tin with a rim around it to prevent the colors from running off. It has a cup in the centre for pure water which is the vehicle for fresco. The colors employed are for the most part the earthen kind and several of the mineral. Those derived from animal or vegetable sources must not be used as they cannot stand the action of lime. A good palette for this work includes the following pigments: lime white (*bianco San Giovanni*); yellow ochre and Naples yel-

low; light red, Venetian red and burnt sienna; terre verte and oxide of chromium; raw and burnt umber; cobalt and ultramarine blue; burnt vitriol (purple); and earth black. A specially prepared vermilion is also used.

Of all the forms of painting *buon-fresco* is the most trying to the artist. He must work rapidly and bit by bit; consequently he cannot see the effects of the colors upon each other. Besides when dry the colors appear lighter and warmer than when first applied to the gray plaster. To cope successfully with all these difficulties, the artist must have long practice and consummate technical skill. The special qualities of fresco are: (1) durability, as the plaster in drying, forms a thin layer of carbonate of lime over the painting, protecting it against moisture and moderate friction: (2) a matt surface, enabling the picture to be seen equally well from all points of view; and (3) clearness, brilliancy and luminosity of color.

We are not certain in what country the fresco process was first used; but it is an established fact that it was known to the ancient Greeks as evidenced by the fragments of painted plaster recently discovered by Schliemann in the pre-historic palace of Tiryns. Marvelously preserved specimens too were found in Pompeii and Herculaneum, notably a small specimen now in the Vatican, known as the 'Aldobrandini Wedding,' and named from the villa near which it was found. The early Christians of Rome also used it in the decoration of the walls of the catacombs. In the Middle Ages this form of painting gave way almost entirely to mosaic. The 14th century, however, saw its revival in Italy, chiefly due to the epoch-making work of the Florentine Giotto (1276-1336). His decorations in fresco of the chapel of Santa Maria dell'Arena created a widespread movement in its favor. Soon it became the leading medium of art expression of his contemporaries and successors and culminated in the sublime achievements of Michelangelo's ceilings of the Sistine Chapel and Raphael's stanze in the Vatican. Since the 18th century fresco painting has gradually fallen into disuse, and all attempts recently made in England and Germany to revive it have met with little success. At present, it is only pursued by a few Siennese mural decorators.

Of the early treatises on the technique of fresco may be mentioned 'Mount Athos Handbook' (Hermeneia, date uncertain); Cennino Cennini, 'Trattato della Pittura' (English translation by Christiana J. Herringham, London 1899). Modern manuals include Taylor, W. B. Sarfield, 'A Manual of Fresco and Encaustic Painting' (London 1847); Cremer, F. G., 'Vollständige Anleitung zur Fresco-Malerei' (Düsseldorf 1891); Ward, 'Fresco Painting, its Art and Technique' (London 1909).

Fresco-Secco.—The form of painting known as *fresco-secco* is a spurious kind of fresco in which the colors are laid on to the plaster after it had been allowed to dry thoroughly. It is used in ordinary house decoration where the true fresco method is impracticable. The process is as follows: After plastering the wall with two coats of lime and sand as in true fresco it is allowed to dry. The surface of the plaster is then rubbed with pumice stone to remove the irregularities; and in the afternoon of the day before the artist intends to do the painting, the wall is saturated with water con-

taining a small infusion of lime. The following morning, after again moistening the wall, the artist traces the outline by pouncing and commences the painting. When during the process of painting the wall becomes too dry, a syringe is employed to moisten it. The colors used are mixed with water or with water and lime as in *buon-fresco*. The advantages of fresco-secco are convenience and ease of execution. On the other hand, works produced by this system are opaque and heavy and the fixation of the pigments are not as complete as in true fresco.

Spirit Fresco.—"Spirit fresco" is the name given to a process of mural painting invented by T. Gambier Parry in 1883 and used with success by Sir Frederick Leighton in his decorations at the South Kensington Museum, England. Great durability is claimed for it by its inventor, and it is now very popular in Great Britain. The wall to be painted in "spirit fresco" is prepared with two coats of plaster as in true fresco; and the surface of the second coat or *intonaco* is left rough, as all smoothing processes destroy its porosity—a quality which is absolutely essential in this system of painting. The use of plaster of Paris and cement are avoided for the same reason. When thoroughly dry, the wall is well drenched with the special medium of the pigments used in this process, diluted in one and a half its bulk of spirits of turpentine. The recipe for the medium as given by Mr. Gambier Parry is as follows: elemi resin (*gum elemi*) two ounces by weight; pure white wax, four ounces by weight; oil of spike lavender, eight fluid ounces; and artists' copal resin, 20 fluid ounces. A few days after spraying the ground is painted thickly with two coats of the medium, slightly diluted with about a third of turpentine and mixed with equal parts of powdered white lead and gilders' whitening. Before proceeding to paint on it, the surface, thus prepared, is allowed to dry for two weeks, at the end of which time it becomes a luminous white, so that all color tones applied on it assume the clearness and brilliancy of true fresco. The painting is done boldly and solidly, using spike oil freely as the solvent. The theory of the process is the saturating of the ground with a solution that forms at the same time the vehicle of the pigments, so that when dry, the whole forms a homogeneous mass. The advantages claimed for it are: (1) durability; (2) power to resist damp and foul air; (3) luminosity of color; (4) a dead surface. Consult Parry, T. Gambier, 'Spirit Fresco Painting' (London 1883).

Stereochromy or Water-Glass Painting.—Stereochromy (from the Greek *στερεός*, *stereos*, solid, firm and *χρῶμα*, *chroma*, color) is a form of mural painting invented by the German chemist, Dr. J. N. Von Fuchs, in 1825, in which water-color is applied on dry plaster and fixed afterward by spraying with a substance known as *water-glass* (a silicate of potassium or of soda). Several different kinds of water-glass are employed. The formulas for the three most generally used are as follows:

(a) *Potash Water-Glass*, composed of 15 parts of pulverized quartz or pure quartz sand; 10 parts well-purified potash; one part powdered charcoal.

(b) *Soda Water-Glass*: 100 parts of quartz; 60 parts anhydrous sulphate of soda; 15–20 parts powdered charcoal.

(c) *Double Water-Glass*: 100 parts of

quartz; 28 parts of purified potash; 22 parts of neutral anhydrous carbonate of soda; six parts powdered charcoal.

In preparing the wall-surface for painting in water-glass three coats of plaster have to be laid. The first two coats are composed of four parts of coarse quartz sand, infusorial earth and powdered marble, mixed in certain proportions to one part of quick-lime, slaked with distilled water. The last coat is composed of eight parts white quartz sand, powdered marble, and infusorial earth to one part quicklime. When the plaster is dry it is sprayed with a solution of hydro-fluo-silicic acid to remove the thin crust of carbonate of lime which forms on it during the process of drying. It is then saturated with two applications of potash water-glass diluted with distilled water, and when dry is ready to receive the painting.

The colors are ground with distilled water only. They are the same as in true fresco with the exception of lime white for which zinc white has to be substituted, as the former does not chemically combine with the water-glass. The colors may or may not be mixed with white. When white is mixed with the pigments, the painting is like an opaque water-color. When white is not used, the work corresponds to transparent water-color. The palette is constructed with small pans to hold the colors. At the end of the day's work the remaining color may either be replaced in the bottle or kept moist in the pan with distilled water.

The actual process of painting in this method is comparatively easy. The artist can paint thinly or in full impasto and may retouch the work at any time. When finished, the picture is sprayed several times with the fixing water-glass, diluted with half its volume of hot water, by means of a special sprinkler. The water-glass penetrates through the plaster to the wall, and in drying binds pigments, plaster and wall into one mass of silicate.

Stereochromy was practised considerably in Germany in the second half of the 19th century especially by Kaulbach, Pettenkoffer and Schraudolf. About the same time Godfried Guffens and Jan Swerts worked in this medium in Belgium. In England, MacIse and Herbert adopted this process in their mural decorations in the Houses of Parliament. Consult Kiem, A., 'Die Mineral-Malerei' (Wien 1881); Kremer, F. G., 'Beiträge zur Technik der Monumental-Malverfahren' (Düsseldorf 1895); Thomas, W. Cave, 'Mural Decoration' (London —).

Painting in Oil.—In oil-painting the pigments are ground in and mixed with an oil varnish and applied on metal, panel or canvas specially prepared. The process arose in northern Europe where the moist climate was not favorable for the development of tempera or fresco. The discovery of the medium has always been attributed to the brothers, Hubert and Jan Van Eyck, who flourished in Belgium about 1400 A.D. But this is erroneous, for as a matter of fact, olive, flax and nut oil were used in their works by painters long before the Van Eycks. On the authority of Eastlake whose 'Materials for a History of Oil Painting' is considered a classic, Aetius, a medical writer of the early part of the 6th century describes at great length linseed and nut oil as used by gilders and encaustic painters of his day. Besides,

there is evidence to the effect that the medium was used in England as far back as 1239. It is true, however, that about the year 1400, the oil process became well established, due no doubt to the Van Eycks who, according to the writings of the Italian historian Bartolommeo Facio, had made a thorough study of the works of the preceding authorities. The system gradually gained popularity all over Europe—so much so, in fact, that by the end of the 15th century, it had become the dominant form of the graphic arts.

The methods of work of several of the old masters representing as many different schools of painting will now be described. The technique of Hubert Van Eyck was as follows: A panel of well-seasoned oak was prepared by being covered with *gesso* which is the Italian word for gypsum or plaster of Paris. On this non-absorbent surface he first made a careful outline drawing in ink or black chalk. He then primed the whole with a light, thin and uniform wash of color diluted with varnish, permitting the drawing to show through. This dry, he painted-in the shadows with a wash of transparent brown. On top of this, monochrome he finally painted the subject in full color, taking care to keep the light parts so thinly covered with paint that the light ground peered through. This is the most primitive form of painting known; nevertheless, it introduced the idea of painting on a prepared monochrome which was taken up and used by the early Flemish and Dutch painters including Rubens, Teniers and Ruysdael. Rubens, however, improved greatly upon the method of the Van Eycks. In his work, brushwork and vivacity of handling generally became important qualities. He, too, painted shadows thin and transparent but loaded in the light parts. Rembrandt, besides the numerous other qualities which characterize a great artist, had great technical skill. He loved rough surfaces and indulged greatly in glazing (brushing transparent colors without admixture of white over a dried undertone) and scumbling (dragging opaque color over the undertone). His brushwork, too, was vigorous and convincing. Frans Hals, whose technique is the model for a great many modern portrait painters, discarded the monochrome system for direct painting. He laid in the shadows thinly, the middle tints substantially and the lights heavily. Titian first laid in his subject in substantial body-color but in simple colors, using, probably, white, yellow ochre, light red and black. After letting this first painting dry for several months, he glazed and reglazed with rich colors every part of the canvas including the high lights. He also scumbled or superimposed opaque color here and there until the work showed that rich surface for which his paintings are famous. His method resembles that of Rembrandt with the difference that Rembrandt indulged more in the scumbling process while he gave preference to glazes. The practice of all the modern painters is based upon one or another of the several methods described.

The materials and tools used in oil-painting include the foundations, pigments, media, driers, brushes, palette and palette knife. The foundations or the materials on the prepared surfaces of which the painting is executed include metal, wood academy-board and canvas. The roughened surface of thin sheets of copper or zinc

make the finest grounds for oil-painting, but are not much used for large pictures on account of the great weight of the metal. Panels of well-seasoned oak or mahogany also make excellent surfaces and have been extensively used. Sketches and small studies are frequently made on a foundation known as academy-board, formed by covering with size and paint a surface made by pasting together several sheets of cardboard. Canvas for oil-painting is the most in vogue. It is prepared as follows: After stretching it tightly on a wooden stretcher, its surface receives a sizing coat of glue and water. When dry it is covered with three successive coats of white lead in oil slightly tinted with black, to produce a gray color.

The colors used by the Renaissance masters were practically the same as those known to the ancients, namely, white-lead, whitening (calcium carbonate), gypsum (plaster of Paris), yellow ochre, raw sienna, vermilion, red oxide of iron, burnt ochre, burnt sienna, lapis lazuli (ultramarine), malachite, terre verte, raw umber, bituminous earth, burnt ivory and lake (extracts of woods, fruits and berries). In recent times very many artificial chemical colors have been added, swelling the list given above to about 215. Out of these only about 15 are now generally used. All the others are fugitive: some of them are affected by sulphur gas or coal smoke; others by light; and others again are permanent when used alone, but deteriorate when mixed with other colors. The following pigments are recommended by the leading chemists and are used more or less by our best contemporary painters: zinc white — ivory black — yellow ochre — strontian yellow — cadmium yellow — cadmium orange — vermilion — rose madder — madder lake deep — burnt sienna — cobalt blue — French ultramarine — emerald oxide of chromium — viridian — burnt umber.

The medium in which the colors are ground and with which they are mixed in the process of painting is a combination of an oil and a varnish. Many different kinds of oils and varnishes were used in the various stages in the development of the process. Among the oils may be mentioned linseed, poppy and walnut oil; and among the varnishes, damar, sandarac, amber, copal, shellac and mastic. At present linseed oil and mastic varnish are mostly used, as they form the most reliable vehicle. Linseed oil is the oil extracted from flax seeds; and mastic varnish is the resin obtained from a small evergreen tree which grows in the Levant. To hasten the drying of their pictures some artists mix their pigments with one of several so-called "driers" now on the market, as, for example, copal megilp. Our best chemists, however, prohibit their use where permanence is desired, and recommend pure spirits of turpentine as the best and only reliable drier.

The brushes employed in this system are made of sable and hog's hair, flat or round. The palette on which the colors are mixed, consists of a thin square or oval piece of wood, generally walnut or pear, hollowed out at one end with a hole through which the thumb is passed. Before laying the pigments on the panel or canvass, they are mixed on the palette with the palette knife—a strip of horn or flexible metal and generally triangular in shape. Some painters of the modern impressionistic

school use the knife as much as the brush in the actual process of painting. Consult Eastlake, Sir Charles, 'Materials for a History of Oil Painting' (London 1847-69); Berger, 'Beitrage zur Entwicklungsgeschichte der Maltechnik' (Munich 1897-1904); Dalbon, 'Les origines de la peinture a l'huile' (Paris 1904); Ludwig, 'Über die Grundsätze der Oelmalerei' (Leipzig 1876); Vibert, 'La science de la peinture' (Paris 1890); Toch, 'Materials for Permanent Painting' (New York 1911).

Pastel.—Pastel is a process of painting in which variously colored crayons are used. The name is derived from the Italian word *pastello*—a little roll of paste—referring to the "paste" into which the colored crayons are first made.

The materials used in the practice of this art include pastels or colored crayons, tinted paper or specially prepared millboard or canvas, and fixative. To make pastels, the coloring substance is first mixed with a colorless base. This combination is then worked by means of a mucilage into the consistence of a soft paste which is formed into small cylinders about two inches long and three-eighths of an inch in diameter. The colors employed are with few exceptions those which are used in oil-painting. The bases or the materials employed to impart body to the colors and to secure light gradations or tints include chalk, pipeclay plaster and oxide of bismuth. Gums arabic and tragacanth are used to bind the molecules of some of the crayons and beeswax of others. The pastels are sold in boxes assorted either for flesh tints or landscape tones. A box usually contains 40 or 50 crayons, hard, medium and soft, giving for each color the gradation of tints from white to the natural tone.

Almost any kind of paper may be used in pastel painting, but those are most suitable which best retain the fine powder of the crayon. The kind specially manufactured for the purpose is the pumice paper—a paper prepared with a coat of starch and charged with pumice powder. To the surface of this paper the pastels adhere tenaciously and are easily blended on it. Besides, a painting executed on this paper can be retouched as often as is necessary without fear that the surface will refuse the crayon. Some pastelists use panels of wood, millboards and even canvas prepared with a pumiced surface. The paper, panel or canvas can be had tinted in many colors—blue, gray, buff, straw, olive and drab. A warm gray is preferred by many for portraits, and a low-toned olive tint is best adapted for landscape studies.

The method of working in pastels is as follows: the general tones of the subject are first rubbed on to the surface of the paper or panel with hard pastels, using the fingers or a stump made of gray paper or the pith of the willow. On these the work is continued and finished in decided touches for accent and texture which are left undisturbed. In comparison with oil-painting, pastel handling is decidedly easy. A skilful artist can complete a study in one sitting. This facility and rapidity are due to the nature of the dry colors used, which may be removed at will, superimposed, left and resumed at any stage and carried to any degree of finish. It forms, therefore, an invaluable medium in which to secure memoranda from nature in

cases where it is necessary to seize fugitive effects of light and shade. For the same reason it is very useful for composing arrangements of color in pictures.

Like all the other forms of painting it has its qualities and defects. Its qualities include charm, delicacy, refinement and brilliancy of color. On the other hand, paintings in this medium are easily effaced and injured by foul air or damp. Therefore, when finished, they are generally "fixed" by a special fixative—the *fixatif Lacaze*—and placed under glass.

It is uncertain to whom is due the merit of the invention of pastel; but there is no doubt that the German landscape painter, John Alexander Thiele (1685-1752), and his contemporary, the Venetian Rosalba Carriera (1675-1757), were the first to carry the art to perfection. Admirable pastel studies of heads and figures in red, blue and black were made by the Frenchmen, Boucher, Watteau and Greuze, and in full color by Nattier (1685-1766), Chardin (1699-1779) and Quentin de la Tour (1704-88), universally proclaimed the greatest pastelists of all times. The first to produce pastels of landscapes and marines was Simon Mathurin Lantara (1729-78). In England, John Riley (1646-91) was the first to practise the art. Later Francis Cotes (1725-70), a pupil of Rosalba Carriera, and John Russel, R.A. (1747-1806), produced pastels which are vigorous and brilliant in color. On the whole, it may be said that in England and still more in the United States this art has never reached a high state of development. In short, pastel is essentially the art of France.

Water-Color Painting.—What is known as water-color is a form of painting in which the medium is water slightly enriched by gum honey or glycerin to make the colors adhere. It was used extensively for decorative purposes by the mediæval monks in their illuminated manuscripts. The art of painting pictures in water-colors, however, was not evolved from these manuscripts, but rather from the pen drawing on paper by the old masters. The Renaissance painters frequently shaded their drawings with flat auxiliary washes of bistre, sepia or India ink. Later the pen outlines were replaced by markings with the brush and full modeling was undertaken in the brown or ink washes, resulting in the full water-monochrome. These monochromes were sometimes tinted to suggested color. In the early part of the 18th century the water-color painters of England often used gray or neutral tint in their distances and a brown in their foregrounds. The progress from this modified monochrome to painting in full color was made by the gradual introduction of blue into the gray, and gold, red and green into the brown. The artists who were the first to produce polychromatic water-color pictures are Paul Sandby, Robert Cozens and Thomas Girtin who flourished in England during the latter half of the 18th century. In J. M. W. Turner (1775-1851) the art reached its highest state of development. In continental Europe and in America water-color has for generations been undervalued as a slight and frivolous medium and has been consequently little practised. However, since 1870, when its qualities became better known, it has been employed by many eminent artists of France, Germany and the United States as an independent form of

expression. At present there are special water-color societies in London, Berlin, Paris and New York which hold annual exhibitions.

As practised to-day, there are three kinds of water-color painting. The first, called transparent water-color, is based upon the principle that the light is to come from the paper. The color is applied in relatively thin, flat and transparent washes depending upon the light paper to give the luminous effect. For example, the pale portion of a greenish blue sky near the horizon on a sunny day will be painted with cobalt blue and a tinge of bамбоге, much diluted with water. The light paper will decidedly peer through this transparent wash making the tone a light and luminous greenish blue. In the darker portion of the sky, as at the zenith, the color applied will be less diluted with water and consequently less transparent; the paper will shine through less making the tone a deeper blue. In the second form of water-color painting light gradations are obtained by mixing opaque white with the pigments and is, therefore, called opaque water-color. The third process consists in the free use of transparent, semi-transparent and opaque tones and is the system now most generally employed. Water-color pigments are sold either in porcelain trays or in tubes. In the tray system the colors are taken up from the trays by the brush charged with water; in the tube system the colors are pressed out from the tubes on to the palette where all mixing takes place. The objections to the tray colors are that they wear out the brushes, and it is impossible to get out a sufficient amount of color at once for certain purposes. Consequently tube colors which are more convenient are more popular. The brushes used in the water-color process are either camel-hair or sable, and the best papers are those named Whatman, Canson, Creswick and Harding. Consult Herrick, H. W., 'Water-Color Painting' (New York 1882); Monkhouse, Cosmo, 'The Earlier English Water-Color Painters' (2d ed., London 1897); Hamerton, 'The Graphic Arts' (Boston 1882).

A. G. SCHULMAN,

College of the City of New York.

PAINTING IN THE UNITED STATES.

The record of American painting does not present the regular developments that are found in the histories of the great schools. There has been no artistic tradition strong enough to unify the efforts of succeeding generations of artists nor has there been for any considerable length of time a settled direction to popular taste. True, in the last century there appeared here an art with certain qualities more or less peculiar to itself and recognizable as differing from what was going on elsewhere, but its whole course was but the time of a man's life, and the ties that held it together were more the result of comparative isolation than any vital demand of national individuality. Our most characteristic artists are found in the latter part of this era which bequeathed to them a steady and single-minded outlook on their work while at the same time the new conditions granted them vivifying contact with the more vigorous arts of the Old World. To-day it is difficult to discern differences in aim between American and foreign pictures.

At the time of the planting of the American

colonies the great European nations with the exception of England were in the midst of epochs of important artistic accomplishment, but Dutch, Flemish, Spanish, Italian, German and French painting left negligible or no results in the New World and no work of art of any merit seems to have found its way here in the early days. When the need for art made itself felt, after the great material difficulties had been overcome and life was somewhat stable, the most prosperous colonies being English it was from England that the artists came. They were called upon to paint portraits, and stiff lifeless effigies they made—imitations of Lely or Kneller. It was poor English work.

The earliest known painter of any excellence was John Smybert, a Scotchman who came to America in 1728 with Bishop Berkeley. He had studied under Sir James Thornhill, the best-known artist in London at the time, where he was a fellow-student with Hogarth. Smybert settled in Boston and painted many portraits, of which the most ambitious is the Family of Bishop Berkeley, now at Yale College, a composition of eight figures. His work was richer in color and more suave in aspect than that of the other early painters, who being engravers or else trained by engravers executed their paintings somewhat in the manner of engravings. Each part was finished separately and the adjoining part fitted to it as well as might be, producing hard dry edges and a total lack of atmosphere. In spite of these crudities or perhaps somewhat on account of them and certainly on account of the artists' simple and child-like point of view their pictures have a charm and also a very real decorative value in the interiors for which they were intended. The most worthy examples of this type of work are found in the portraits of Jonathan Blackburn who settled in Boston about 1750.

Both Smybert and Blackburn served as models for the one painter of real talent in the colonies, J. S. Copley. He was born in Boston in 1737 and was trained by his step-father, Peter Pelham, an engraver of merit and also a painter of portraits. In Pelham's house he had the opportunity of coming in contact with all that Boston afforded in the arts, as well as becoming cognizant of the engravings of the excellent portraits which were beginning to be produced in England. The knowledge of these Copley put to use in adapting from them general arrangements for his own youthful work as well as elegant accessories, rich costumes, jewels and the like—luxuries which the colonies could not furnish at that time. He was immediately successful and painted a great number of portraits (about 275 are known) before his departure for England just before the Revolution. Up to that time his work improved steadily. In England where he also prospered his paintings lost their peculiar flavor and he worked more and more in the manner of the accomplished English artists of that day so there appears but slight resemblance between his late pictures and those executed in America.

Benjamin West, a Pennsylvanian, was of the same time as Copley. In the face of great difficulties he began the study of art (the story says he got pigment from the Indians) and soon made his way to London where he won the notice and friendship of King George III and

attained a position of eminence. He was instrumental in inducing the king to found the Royal Academy and on Reynolds' death he succeeded to his position as its president. His bombastic pictures of religious, historical or allegorical subjects were executed in a formula vaguely founded on that of the then popular Italian eclectic painters of the 16th and 17th centuries. They were highly appreciated by his royal patron and many others of the time but have since fallen into complete disfavor. His lasting work was the encouragement he gave, during his whole career, to the young American painters who went to London to study, all of whom were his pupils.

Charles Wilson Peale was one of these. Though born in Maryland, his career shows him to have had the Yankee characteristic of ingenuity in any position he turned to—army officer, politician, mechanic, painter, he was all in turn, besides being the founder of the first American museum situated in Philadelphia where art works, curiosities and natural history specimens were exhibited. His portraits are like those of the earlier painters, stiff and wooden, but are the best which America could show for 15 or 20 years after Copley's departure. Another ingenious pupil of West's of about this time was Robert Fulton who after a passable success in his painting early abandoned it to devote himself entirely to his mechanical inventions.

A new phase of this period of American painting which displays an accomplishment worthy to be considered with the best of English contemporary work was ushered in on the return of Gilbert Stuart, a painter of great talent. He was born in 1755 in Newport, R. I., studied and practised his profession in England from 1775 until 1792 when he came back to his native country. Although a pupil of West no traces of West's influence appeared in his output. He founded himself rather on the English portrait-school then at its highest development. He was fortunate in his sitters, who included many of the prominent people of the early years of the republic, and he fixed for us the accepted type of likenesses of Washington. Three portraits of Washington it appears were executed from life—the first was destroyed, the second, a full length for Lord Landsdowne and the other the unfinished head now in the Boston Museum. From these he made many replicas, varying much in degrees of excellence. Stuart's interest centred in the heads of his sitters. He was apt to slur over all the other parts and never attempted elaborate compositions.

The best known of the later pupils of West were Allston, Malbone, Morse and Sully. These were the last of the Americans who accepted complete allegiance to the English school and with them ends the first period of painting in America. Washington Allston's importance is greater than his pictures. He was one of the few who felt the influence of the character of West's subjects and he was the first in America to paint pictures of an imaginative and poetic bent. His contemporaries rated him as a genius while we of to-day can only find in his work a sweet sensitiveness or a yearning for great things which he was unable to realize. He was of that not infrequent type of American artist who when withdrawn from the stimulus that

excites him seems incapable of accomplishing what his career under more favorable conditions promised. S. F. B. Morse, one of the excellent portrait painters that America has produced, had in some of his works a rare feeling for vitality and character. His inventions were, however, too engrossing for his art and from the time he began to develop them he ceased to paint.

Malbone during his stay in London studied the English miniaturists, Cosway, Plimer and the others, to such advantage that his work in this branch of art remains the best that America has produced. Thomas Sully was born in England but came to America when an infant and learnt here the rudiments of his art. West's tutelage left no marks on his work but he formed himself with happy results on the study of Lawrence, Raeburn and Romney. His career in America was long and successful. He lived until 1872.

With the growth of wealth and power in the early 19th century came a sense of national self-confidence which with the severance of the dependence of America upon the mother country brought about the gradual weakening of the force of English precedent. The younger artists relied more on the training that could be got at home and when they went abroad it was as artists not as students. They traveled in various places without attaching themselves to any one teacher. The changed conditions of life too in which the aristocracy of the older period was giving place to the crude force of the new democracy made itself felt in the pictures. Chester Harding who had been a peddler, inn-keeper, sign-painter as well as artist, John Neagle and Henry Inman, who both worked somewhat in the style of Stuart and Sully, were then the principal portrait painters. William Mount and R. Caton Woodville began painting genre pictures of American subjects which were much prized by the picture buyers. But the principal activity was manifested by the landscapists. It was the period alluded to in the first paragraph of this article when painting in America had a character of its own. The delight in native scenery and the belief in its superior grandeur to anything the Old World could furnish were prevalent among both the public and the painters and furnished the common point of view which is the first requirement of a school of art. The high prices paid for these landscapes, the highest which any group of American artists have ever received, as well as the comments of the time, show their wide popularity. The artistic centres of other days, Boston and Philadelphia, with their traditions of colonial aristocracy yielded their places to New York, as that city owing to its commerce became the wealthiest of the country. The National Academy of Design was founded there in 1826. Most of the popular landscapes were those of views within reach of New York, particularly scenes of the Hudson River Valley, from which the popular name of the whole group, the Hudson River School, is derived. The New York picture buyer has thus the added interest of a knowledge of the localities represented; the pleasure of recognition of familiar sites being always a satisfaction for those who are new to the appreciation of art.

Thomas Doughty was the first of the group

in that he painted many pictures of the Hudson River Valley without too obvious foreign influence. Asher B. Durand, somewhat his junior, did not devote himself exclusively to painting until middle age, up to which time he had worked at his profession of engraving. He traveled abroad, studied Constable and Turner and was interested particularly in the facts of landscape. He might be called the realist of the school in distinction to the idealist Thomas Cole who like West attempted allegorical subjects and ethical teachings in his pictures. Cole was born in England but came to America when 19 and soon took up the life of a wandering artist, doing whatever jobs he found. He later visited England, France and Italy and his pictures, more professional in appearance than those of his contemporaries, show the effect of his longer contact with Europe. His greatest success was with series of pictures of which the 'Voyage of Life,' with figures typifying infancy, youth, manhood and old age in boats on a river, and 'The Course of Empire,' four views of the same landscape showing four stages of the history of a city from settlement to destruction, were famous types.

The younger men ranged themselves under Durand or Cole according to their temperaments. Many of them started as engravers and their close imitation of detail often displays the engraver's method. John F. Kensett was the chief of those who followed Durand. He portrayed the native scenery as he and his clients saw it with successful financial results and his pictures which were once the furor of collectors still appeal in some instances on account of their probity and sincerity. As late as 1873, the year of his death, his vogue was unabated as is shown by the sale of the pictures and studies left in his studio for over \$150,000.

Frederic E. Church who had a greater talent than any of the school was a pupil of Cole, from whom or from Turner's pictures of theatrical effect he imbibed the love of the "grand subject." And to make his subjects grand he not only chose the most immense views such as the 'Heart of the Andes,' or the most famous remains of art such as the excellent picture of the Parthenon, but combined physical and artistic wonders in one picture, as in the Ægean Sea where the Golden Horn, the Acropolis, a rock temple, sunset, rainstorm, a double rainbow are crowded together with ingenuity and considerable skill.

There were many artists who gained fame and fortune at this time, but the few names chosen are representative ones and may stand for the accomplishment of the whole number. Their success was confined to America with the exception of Church who won a considerable admiration from abroad. By the end of the third quarter of the century their popularity showed signs of waning. Artists who had had a thorough training in Munich or Paris had returned and their criticisms were beginning to have effect. The old order was passing and its descendants, men like Wyant, Martin and Inness, who inherited certain of its principles were enough in touch with foreign art to see and avoid the circumscriptions of their predecessors. With the enlightenment of the public, the assured connection between artist and client came to an end. Even Tuckerman, the enthusiastic chroni-

cler of mid-century artists, admits that from European standards American artists were remunerated far beyond the market value of their pictures. It was due, he says, to the "sudden prosperity of an imperfectly educated class" who "with little discrimination, and as a matter of fashion devote a portion of their newly acquired riches to the purchase of paintings."

Of the landscapists who followed, Alexander Wyant more than the others was affiliated with the Hudson River School. His foreign training was secured in Germany. He painted native scenes in the spirit of Durand, but in place of a dry insistence on detail he succeeded in enveloping his paintings in an atmosphere and in expressing a poetic mood. Homer Martin was of the same calibre but more intense. His outside influences came from the French and some of his later paintings have an aspect which approaches that of the Impressionists. The merit of George Inness is still more prominent. Distinctly a visionary and romantic he combined the rich color of a Delacroix or a Dias with American motives. He had a lofty and what might be called a religious outlook on nature and many of his pictures have a grandeur that would be acknowledged in any company.

The most personal artist that America has produced, Winslow Homer, should be mentioned at this point. He began as an illustrator, making drawings for a magazine during the Civil War. His work at that time, as later, was distinguished by the grim determination to express the significant quality in each person or thing portrayed. His subjects at first did not differ from those of the figure and genre painters, his contemporaries, whose general training was similar to his, but he had what they lacked, a great talent and an inherent sense of what was properly the distinctive province of painting. When later he came in touch with foreign art (the influence of Courbet counts largely in his development) he was stimulated to great progress, keeping distinct his own point of view the while. In his youth he painted soldiers, negroes, genre pictures, such as were the subjects of his drawings for reproduction. These gave place to scenes of life in wild places with hunters, or fishermen, or sailors; to rugged landscapes of the seashore, or forest, or mountain streams—powerful pictures with a scorn for prettiness or decorative effect. All his works are imbued with the qualities which one likes to think of as American; they are straightforward, vigorous, even to uncouthness at times, and self-reliant. He was the Abraham Lincoln among painters.

Albert P. Ryder, also a distinct personality, is the antithesis of Homer in temperament. A poetic dreamer, timid and self-questioning, he produced but little. Certain of his pictures, however, rank with the best achievements of American art. No American has equalled his intensity of realization of imaginative themes. His training has been native and more or less haphazard. Each of his little pictures seems to be a fresh experiment but he attains a deep glow of beautiful expressive color at times and a rare quality of fused surface. His realm is the borderland between fancy and reality. He paints visions of old legends—fairy stories, gaunt trees by moonlit streams, boats on lonely

seas. It seems almost impertinent to attempt to trace the parentage of so personal and sensitive a talent, but those who take an interest in such matters may find it was fostered by the smaller and simpler imaginative works by Cole or by an admiration for Turner.

Before proceeding to the present stage in our genesis, that of the painters thoroughly trained in foreign countries, mention must be made of George Fuller, who escaped from the tyrannies of fact by bathing his scenes in a dull, hazy atmosphere, where all outlines are blurred and all colors take on a tawny shade; and also of Thomas Eakins, who though he spent some time in Paris under Gérôme, never attempted the French methods of his fellow-students in the Beaux-Arts School. He was an uncompromising realist. His favorite subjects were portrayals of surgical operations at hospitals, prize-fights and the like, and his portraits, dull and heavy in color and surface, have a vigor of characterization and an intellectuality that gives them distinct value as documents of our time.

With certain reservations, what may be called the national period of American painting ends with these men. The beginning of our present cosmopolitanism took place not long after the middle of the century, when William M. Hunt returned from abroad and began practicing his profession at a time when the Hudson River painters were in the heyday of their success. He had studied under Couture and was deeply influenced by J. F. Millet long previous to that artist's general recognition. His eloquent championship of the French art which he represented was instrumental in preparing for the change which was soon to take place. A gentleman of impressive personality, he never lacked his circle of admirers, but his art was alien to the public at large. The disassociation between artists and public which now prevails in America seems to have been inaugurated in his case. It is hard for this generation to appreciate how his excellent portraits could not have appealed to the people of the 60's or his subject pictures, generally arrangements of models, which were in a style compounded of Couture and Millet. In his decorations for the Albany State House, now covered over, he gave America her first mural paintings in a monumental style.

John La Farge was a friend and coworker of Hunt. He was born in America of French parents and took up the study of painting under Couture in Paris. He was a man of wide knowledge and attainments, and the profession of art was one of several possibilities which were open to his varied talents. His chief activity was in the field of decoration of wall surfaces and more famously of windows in stained glass in a method of his own, the foundation of which was a glass made of two or more colors fused together imperfectly in the same piece instead of flat colors formerly used. La Farge's example has been widely felt, particularly in church decoration, but in both his career and in that of Hunt the promise of the talent seems inadequately fulfilled.

While Inness, Homer, Hunt and La Farge were working their way to a somewhat restricted appreciation, the general taste was still loyal to the great reputation of the time of the Civil War and before. It remained so until the

late 70's. By then a number of young artists, thoroughly equipped in the Munich and Paris schools, had returned home and were sending their works to the exhibitions of the National Academy. Dissatisfaction with the places which their pictures were accorded in these exhibitions led to the formation of the Society of American Artists in 1877. For more than a score of years the exhibitions of the society represented the European influence in American art, at the end of which time the European ideals having generally prevailed and the aspect of the exhibitions of the rival associations having become practically the same, the society was merged into the academy. Since the formation of the society with the exception of the work of a few artists of strong individuality or of those who were formed under the old régime, American painting has echoed either the Munich or the French fashions. The most famous of the Munich men are William M. Chase and Frank Duveneck. In the category of those who have imported the rapid and vigorous developments of the French school the names are many. From the impressionist movement which produced John Twachtman, Alden Weir and recently Ernest Lawson, up to the late phase of the disciples of Cézanne, which has given us Maurice Prendergast, John Marin and Max Weber, Americans have expressed their versions, often very personal ones, of the æsthetic ideals of Montmartre and Montparnasse. Arthur B. Davies has retained up to recently his independence from the foreign ideals of the time. In his earliest work he showed himself a romantic of the Ryder sort but with a greater vitality than that artist. His pictures of legend and fancy or of noble landscape peopled with creatures of his imagination are distinguished by a very individual composition and an exquisite sense of color and form. He has lately exercised his rare gifts in a method adapted from the principles of the so-called Cubists, whose prophet is Picasso, a developer of the style of Cézanne.

Of the cosmopolitan painters, two have attained world-wide fame—Whistler and Sargent. Both made Europe their home. James McN. Whistler was a contemporary of La Farge and the junior of Hunt by but 10 years. His artistic training was entirely European, only a few years of his youth having been spent in this country. Super-refinement and sensibility are the keynotes of his character. Strange to say he was influenced by the most rugged of all 19th century painters, Gustave Courbet, whose work was the stimulus to so much of the later art. Whistler was egotistical and conceited, but in his painting he displayed a real genius. His work at various times shows widely different inspirations—Courbet, as has been mentioned, certain contemporary English painters, Velasquez and the early 19th century Japanese—but always has the same charm of sensitiveness and delicacy. His themes were those of reality, but the vagueness and mystery of twilight pervade his lovely canvases. He painted portraits in which the subjects appear to have the artist's own characteristics of nervousness and preciousness; landscapes in which a view that may be of factory chimneys and ugly bridges is made to look as exotic as a glimpse of Tokio in a print by Hiroshige;

pictures where a London garden resort at night with strolling or dancing pleasure-seekers in prosaic clothes takes on the aspect of a festivity in a fairy-tale. He ranks with distinction among the group of Frenchmen of whom Degas and Manet are the principal names.

John Sargent has had even less connection with America than Whistler. He was born abroad of American parents, studied in Paris under Carolus Duran and has since lived continuously in England. His career has been unvaryingly successful both in popular approval of the better sort as well as in the admiration of his fellow-artists. His work, largely portraits, from the first assumed the manner for which he is still famous, a striking likeness accomplished with a swift and fluid brush-handling. He does not seem to interest himself in profound characterizations as much as in peculiarities of appearance so that in certain instances his work approaches to the border of caricature. In the last few years he has confined himself to a series of paintings of religious subjects for the decoration of the Boston Public Library and to small pictures of landscapes with figures, all of which are marked by the same remarkable vision and the same nimbleness of hand that his portraits exemplified. Contemporary portrait painting in this country has been largely influenced by his work.

Only the fewest necessary names out of the many that might have been mentioned have been commented upon in this cursory account. Our art history might be epitomized in one paragraph as follows: From the end of the 17th century when the practice of art began in the colonies up to the second quarter of the 19th century it was purely English and this English period was prolonged in isolated cases for the lifetime of its representatives. The native school had its rise in the early part of the 19th century, attained about 1825 pre-eminence which lasted until the late 70's, and which was wrested from them by the foreign-trained artists. Among the latter were working certain painters who infused qualities of the native school with the foreign outlook, but broadly speaking the later painters are frankly cosmopolitan and have taken their places, often highly honored ones, in the company of their fellow-artists of Europe.

For the sake of brevity, qualifications which should have been made to some of the statements of this article have been omitted. Isham's 'History of American Painting' (which contains a bibliography) is recommended to those who wish fuller information as to the facts. Consult Bryant, L. M., 'American Pictures and their Painters' (1916).

BRYSON BURROUGHS,
Curator of Paintings, Metropolitan Museum of Art, New York.

PAINTINGS OF THE GREAT MASTERS. The 12 most famous paintings are: Leonardo da Vinci's 'Last Supper,' 'Mona Lisa'; Raphael's 'Sistine Madonna'; 'Madonna of the Chair'; 'La Belle Jardinière' and 'Transfiguration'; Michelangelo's 'Last Judgment'; Rembrandt's 'Night Watch'; Correggio's 'Nativity' (*Notte*) and 'Magdalen Reading'; Rubens' 'Descent from the Cross'; and Guido Reni's 'Aurora.' An entire encyclopedia

would be required to catalogue, classify and describe *all* the celebrated paintings of *all* the great ancient and modern masters and to show the progress of art and the characteristics of the "schools," or various groups of painters. Here is given an account of the most celebrated paintings and kinds of paintings, from ancient times to the present; in other words, from the Greek Zeuxis to the Spanish Zuloaga,—a period from 450 B.C. to the year 1919. The article is arranged thus: I. Ancient; II. Early Christian Art; III. Religious; IV. Portraits; V. Military, Guilds and Historical Events; VI. Landscapes; VII. Marines; VIII. Animals and Birds; IX. Flowers, Fruits and Still Life; X. Architecture; XI. Genre; XII. Mythological and Fanciful; XIII. Bibliography.

I. Ancient.—Painting was highly developed 4,000 years ago, as wall-decorations in Egyptian tombs show. No Grecian paintings have come down to us, but there are records of artists and their works. The 'Taking of Troy' and 'Visit of Odysseus to Hades,' painted by Polygnotos of Thasos in the public hall of Delphi, were admired by Pausanias, who saw them 600 years after their execution. 'Helen,' painted by Zeuxis of Heracleia (born about 450 B.C.) for a temple of Hera in Croton, was one of the great works of antiquity. Zeuxis painted a 'Bunch of Grapes' so perfectly that some birds flew toward it and pecked at the shining globes. Parrhasios of Ephesus invited Zeuxis to come and see his new picture. On arriving in the studio Zeuxis asked him to draw aside the curtain and show it to him. The curtain was the picture! Apelles of Cos, who worked between 350 and 310 B.C., was considered even greater than those painters. His 'Venus Anadyomene,' the goddess rising from the sea, executed for the temple in Cos, was carried to Rome by Augustus, who remitted tribute to the island because of it. Apelles also painted a portrait of 'Alexander the Great,' as Jupiter, for which he received 20 talents (about \$25,000). Roman painting followed Grecian styles. In Julius Cæsar's time Timomachus of Byzantium enjoyed a great reputation. His 'Ajax and Medea,' celebrated in epigrams, was bought by Cæsar for 80 talents (\$100,000) and placed in the temple of Venus Genetrix.

II. Early Christian Art.—The ideal of the Christian, differing from the Greek, developed a new art; but the earliest examples of Christian painting (Catacombs of Rome and Naples) show classical treatment: Christ as Orpheus taming wild beasts by the sound of his lyre; Christ as a shepherd; Elijah going to heaven in a chariot like Apollo's, etc. Paintings were figurative and expressed doctrines. In the first years of the Christian Church the Virgin was represented alone and as an Orante—her arms extended in the act of prayer as then practised. After the Council of Nice (325 A.D.) churches were dedicated to the Virgin, and she was represented as Queen of Heaven. After the Council of Ephesus (431 A.D.), when the doctrine of the Incarnation was established, the Virgin and Child were painted together. The art of the painter followed the teachings of the pulpit. (See CHRISTIAN DOCTRINE, DEVELOPMENT OF). The "Assumption"—the Virgin coming to life and rising bodily into the air—began to be painted in the 11th century. The "Coronation

of the Virgin" became popular in the 13th century. The Virgin as the "Immaculate" one dates after the Council of Trent (1545), which settled Mary's genealogy. As the *Immaculata* Mary stands apart from mankind, even from her son. The first pictures show her standing on the moon and crowned with stars—a poetic idea. Murillo (1618-82), who painted the most beautiful examples of the "Immaculate Conception" (particularly the one in the Louvre), placed the crescent moon in the clouds below the feet of the Virgin. The "Madonna in Glory"—sitting or standing in the clouds with the child in her lap, or in her arms—was a painter's vision rather than an ecclesiastical idea. It made its appearance in the time of Raphael. One of the finest examples is his 'Madonna di Foligno,' named from the town of Foligno in the background. It shares a room in the Vatican with Raphael's 'Transfiguration' and the 'Last Communion of Saint Jerome,' by Domenichino (1581-1641); the 'Sistine Madonna' (Dresden), also represents the Madonna in glory.

III. Religious.—Giovanni Cimabue, born in Florence in 1240, is the connecting link between the ancient and modern idea. Cimabue ends the long Byzantine line of painters that had flourished in Italy from the time of Constantine to the 13th century. His most celebrated Madonna was painted for the church of Santa Maria Novella, Florence, to which it was escorted from the artist's studio in a triumphal procession. It has never been removed. In the angular Byzantine type of the "Madonna of Santa Maria Novella," there is an attempt at human expression and the Child holds out his hand in a way that was novel in the 13th century. The adoring Angels are conventionally Byzantine. Giotto (1266-1337), the shepherd boy discovered and trained by Cimabue, was the first to seek inspiration from nature. His frescoes in Florence, the life of 'Saint John the Baptist' (Peruzzi Chapel) and the life of 'Saint Francis' (Bardi Chapel), became models for future generations. While Cimabue and Giotto were fusing new life into Byzantine traditions, the Sienese painters were doing the same. Duccio di Buoninsegnà (1260-1340) produced a 'Madonna and Child' surrounded by 20 angels, six saints and four patrons of Siena. The work was carried in a procession to the Cathedral of Siena. Duccio shows more grace and charm in his figures and faces than the Florentine masters. Simone Martini, often called Simone Memmi (1284-1344), holds the same place in the Sienese School that Giotto does in the Florentine. Painting now developed rapidly in Italy and in the Low Countries, where Jan (1391-1440) and Hubert van Eyck (1366-1426) perfected the art of painting in oil. Most of the early or "pre-Raphaelite" paintings were religious, although the madonnas and saints appearing in them are models from the artists' friends or families, and the landscape backgrounds familiar and loved scenes. The 'Madonna and Child' was the most popular of all subjects. Sometimes they are represented alone, sometimes with the little Saint John, or with Saint Anne, or Saint Joseph or with a group of saints. The madonnas of Raphael are the best loved. The 'Sistine Madonna' (Dresden) is, perhaps, the most

famous of all paintings. It was painted on canvas for the Cistercians of San Sisto of Piacenza in 1515-16 and sold by a later generation of monks to Augustus III of Saxony. Altar hangings are seemingly drawn back to reveal the vision of the Virgin floating in heaven holding a child of mysterious beauty and surrounded by angel heads and clouds. Pope Sixtus looks upward and Saint Barbara looks downward at the two angel children, who gaze in rapture at the beautiful Virgin. Next in popularity comes the 'Madonna della Sedia' (Pitti), painted in 1515. This 'Madonna of the Chair' is full of tender maternal feeling and is intensely human. Almost as beloved is the Madonna with the Infant Christ and Saint John (Louvre), known as 'La belle Jardinière.' Little Saint John holds a cross before the Child, who looks at his mother questioningly. The landscape is exquisite and the pose of the Virgin graceful and distinguished. The same group appears in the 'Madonna del Cardellino' (Uffizi), in which Saint John offers Jesus a goldfinch, whence the name. Raphael's 'Holy Family,' known as 'The Pearl,' passed into England to Charles I with the Gonzaga collection. When Philip IV purchased it, he exclaimed: "This is my pearl!" The name has clung to it. Another famous work is the 'Virgin of the Rocks' (Louvre and replica in National Gallery, London) by Leonardo da Vinci (1452-1519). Of particular grace and fanciful loveliness are the madonnas by Botticelli (1447-1510): 'Madonna of the Magnificat' (Louvre), 'Madonna of the Melegnano' (Uffizi) and 'Rosebush Madonna' (Uffizi). The 'Madonna of the Cherries' (Vienna) by Titian; the 'Madonna of the Cut Pear' (Vienna) by Dürer (1471-1528); and the 'Meier Madonna' (Darmstadt and copy in Dresden) by Holbein (1497-1543) are celebrated.

The 'Annunciation' was the next favorite subject to the Madonna and Child. The angel Gabriel always stands on the left side of the spectator. Early pictures show him empty-handed. In the great pictures of the Renaissance he bears the "Annunciation Lily." The greatest of all "Assumptions" is the one by Titian (1477-1576) in Venice. The 'Adoration of the Magi' (illustrating the doctrine of the Epiphany), afforded a fine opportunity for wealthy men of distinction to pose as the Three Kings offering gifts to the Holy Child. Among the greatest are by Ghirlandajo (Hospital of the Innocenti, Florence); Botticelli (Uffizi and Hermitage); Veronese (Dresden), Lochner (15th century) in Cologne Cathedral; and Rubens (Antwerp and Prado, Madrid). Correggio's 'Notte' (Night) or 'Nativity' (Dresden), is an 'Adoration of the Shepherds.' It is particularly famed for its effect of light, which radiates from the Holy Child. One of the most celebrated of all pictures is the 'Last Supper,' Leonardo da Vinci (1452-1519), painted on the wall of the Refectory of Santa Maria delle Grazie, Milan. It has almost faded from view. "The Descent from the Cross," Rubens (1577-1640), another masterpiece, was removed from Antwerp Cathedral for safety during the German invasion in 1914. Raphael's 'Transfiguration' (Vatican) left unfinished by Raphael, was hung over his bier. The most famous head of Christ is, the 'Ecce Homo'

(Dresden), Guido Reni (1575-1642). The most noted modern pictures representing Christ are the 'Light of the World' (Keeble College, Oxford), Holman Hunt (1827-1910), and 'Christ before Pilate' (John Wanamaker, Philadelphia), Munkacsy (1844-1900). Other religious paintings in the front rank among masterpieces are 'The Last Judgment' (Sistine Chapel) by Michelangelo (1475-1564); the 'Last Judgment' (Campo Santo, Pisa) attributed to Orcagna (about 1308-68) and also to the Lorenzetti brothers of Siena; the great altar-piece, the 'Adoration of the Lamb,' by Jan and Hubert van Eyck (Saint Baron, Ghent, panels in Berlin), 'Paradise' (Doge's Palace, Venice) with its 1,000 figures by Tintoretto (1518-94); 'Marriage at Cana,' by Tintoretto; the 'Mystic Marriage of Saint Catherine' (Louvre) Correggio (1494-1534); 'Marriage of Cana' (Louvre) by Veronese (1528-88); and 'Holy Grail' series (Boston Public Library) by Edwin Abbey (1852-1911).

IV. Portraits.—All great painters were great in portraits. They earned the chief part of their income by this means. Portrait-painting became an independent art in the 15th century. The Flemish and Italians executed marvels. The 'Man with the Pink' (Berlin) by Jan van Eyck (1381-1440); the 'Banker and His Wife' (Louvre) by Quentin Massys (1466-1530); and the 'Old Man and Boy' (Louvre), the former with a terrible nose, by Ghirlandajo (1440-94), are remarkable examples of direct painting. Gentile Bellini (1426-1507) and Giovanni Bellini (1428-1516) are among the earliest Italian portrait-painters. Gentile's 'Portrait of Sultan Mahomet II' (Lady Layard) is famous, and Giovanni's, 'Doge Loredano' (National Gallery, London) is a great work of art. Donors of altar-pieces frequently had themselves represented on the panels and outside shutters and sometimes in the important central panel kneeling in adoration of the Virgin and Child. Wealthy merchants and artistic princes delighted in having themselves reproduced in magnificent attire in Adoration of the Magi. Female saints, as well as the Madonna, afforded the painters opportunity for perpetuating the faces and figures of loved ones. These wonderful women that look upon us from canvases, centuries old yet ever young and lovely, are real women dear to the painter,—his wife, or his love. For example, Raphael's 'Sistine Madonna' and 'Saint Cecilia' (Bologna) are idealized studies of 'La Fornarina' (Barberina Palace), his one love; and Andrea del Sarto's handsome though shrewish wife, Lavinia Fede, posed for the 'Madonna of the Harpies' (Pitti) and 'John the Baptist' (Pitti). The most famous of all portraits is Leonardo da Vinci's 'Mona Lisa' (Louvre), with the enchanting smile, the wife of Francisco del Giocondo, whence its name 'La Gioconda.' Among Titian's magnificent portraits are: 'Lavinia,' his daughter (Pitti); 'Man with Glove' (Louvre); and 'Portrait of Himself' (Berlin). Raphael's great portraits are 'La Fornarina' (Barberini Palace, Rome); 'Pope Leo X, with Cardinals Giulio de' Medici and Luigi de' Rossi' (Pitti); 'Pope Julius II' (Uffizi and replica Pitti); and 'Balthazar Castiglione' (Louvre). The 'Portrait of a Tailor' (National Gallery, London), by Moroni (1510-

78), is a masterpiece. 'Beatrice Cenci' (Barberini Palace, Rome), by Guido Reni (1575-1642), occupies a place by itself. The 'Concert' (Pitti) by Giorgione (1475-1511), is a group of portraits, superbly rendered. Hans Holbein the younger (1497-1543), painted masterpieces: 'Erasmus' (Louvre) and 'Georg Gisze' (Berlin) head his list.

Velasquez (1599-1660) produced magnificent works: 'Pope Innocent X' (Doria Palace, Rome); four pictures of the young 'Baltazar Carlos' (Prado, Madrid) and 'Las Meninas' (Prado) or 'Maid of Honor,' in which he painted himself painting the group, are usually considered the greatest. The list of Rembrandt (1606-69) is long. In addition to many of 'Saskia,' his wife, and himself, those of 'Elizabeth Bas' (Rycks) and 'Old Woman' (Petrograd) are notable. Frans Hals (1584-1666), is ranked with Rembrandt. His 'Laughing Cavalier' (Wallace, London); 'Nurse and Baby' (Berlin) and 'Jester' (Rycks) have never been surpassed in dash, vigor and breadth. Of Rubens (1577-1640) 'Helen Fourment' (Hague) is the loveliest of the many of his second wife. The 'Chapeau de Poil' (National Gallery, London), is another famed example. Of Anthony Van Dyck (1599-1641), 'Charles I' (Louvre); 'Children of Charles I' (Turin); and 'James Stuart, Duke of Richmond' (Metropolitan Museum, New York), are masterpieces. 'Cardinal Richelieu' (Louvre), by P. de Champaigne (1602-74), is noted. Hogarth (1697-1764) is one of the masters of portraiture: 'Lavinia Fenton as Polly Peachum' and the 'Shrimp Girl' (National Gallery, London) stand high. The beauties of the court of Charles II, particularly 'Barbara, Duchess of Cleveland,' as 'Minerva,' by Sir Peter Lely (1618-80), deserve their reputation. The French Nattier (1685-1766) painted with lovely color and fancy: 'The Duchesse de Chartres' (Stockholm) in mythological costume is exquisite. In the front rank are placed Thomas Gainsborough (1727-88) and Sir Joshua Reynolds (1723-92). Gainsborough's 'Mrs. Siddons' (National Gallery, London); 'The Blue Boy' (Duke of Westminster); and the 'Duchess of Devonshire' (the stolen picture recovered and bought by the late J. P. Morgan) and the 'Hon. Mrs. Graham' (National Gallery, Edinburgh) are noted for their distinction and style. Sir Joshua Reynolds list of superb works is too long to enumerate. 'Mrs. Siddons as the Tragic Muse' (Duke of Westminster and sold in 1919, replica Dulwich); 'Nellie O'Brien' (Wallace, London); 'The Strawberry Girl' (Wallace); and 'Age of Innocence' and 'Angel Heads' (both in the National Gallery, London) are the favorites. George Romney (1734-1802) is celebrated particularly for his lovely portraits of 'Lady Hamilton.'

American painters succeeded early in portraiture. Gilbert Stuart (1775-1826) is noted for his 'Washington' (Museum of Fine Arts, Boston). 'General Dearborn' (Art Institute, Chicago) is another fine example. Among other notable works are 'Alexander Hamilton' (Metropolitan Museum, New York), by John Trumbull (1756-1843); 'Fanny Kemble' (Pennsylvania Academy of Fine Arts, Philadelphia), by Thomas Sully (1783-1872); 'Mr.

DE VINCI.

DE ERASMO.

GUIDO RENI.

RUBENS.

CORREGGIO.

and Mrs. Izard' (Museum of Fine Arts, Boston), by John Singleton Copley (1737-1815); 'Portrait of the Artist's Mother' (Louvre), Whistler (1856-1916); 'Beatrice Goellet' (privately owned) and 'Carmencita' (Metropolitan Museum, New York), by John S. Sargent (1850); and 'Lady with the White Shawl' (Pennsylvania Academy of Fine Arts, Philadelphia), by William M. Chase (1849-1916).

Among other famous modern portraits are the 'Lady with the Glove,' his wife, painted in 1869, (Luxembourg), by Carolus-Duran (1837) and 'Daniel Zuloaga and his Daughters' (Luxembourg) by Zuloaga (1870).

V. Military, Guilds and Historical Events.—In the Low Countries civic guilds and military companies were fond of having their portraits painted in groups. Chief among these paintings is Rembrandt's 'Night Watch' (Rycks), one of the most celebrated of all paintings. His 'Syndics' (Hague), a group of cloth-merchants, and 'Lesson in Anatomy' (Hague), a group of doctors, come next. The 'Banquet of Arquebusers' (Rycks) by Bartolomeus Van der Helst (1630-70) is a wonder of realistic painting and splendid color. 'Saint George's Guild Banquet' and 'Saint Andriaen's Doelen' and other groups (Haarlem), by Frans Hals (1584-1666) are magnificent. Famous military works are: 'Friedland—1814' (Metropolitan Museum, New York) by J. A. Meissonier (1813-91) and 'Champigny' (Metropolitan, New York), by Detaille (1848). Pictures commemorating historical events are numerous. Rubens painted many such, including the famous series of 'Henri IV and Marie de' Medici' (Louvre). Notable works are: Velasquez's 'Surrender of Breda' (Prado, Madrid); the 'Peace of Münster' (National Gallery, London), by Ter Borch (1608-81); the 'Coronation of Napoleon' (Louvre), by David (1748-1825); and the 'Signing of the Declaration of Independence,' 'Surrender of Burgoyne,' 'Surrender of Cornwallis at Yorktown' and 'Resignation of Washington' (Capitol, Washington), by John Trumbull (1756-1843); 'Washington Crossing the Delaware' (Metropolitan Museum, New York), by Leutze (1816-68), is entirely imaginary and owes its popularity to the subject.

VI. Landscapes.—Beautiful landscapes appear in early Italian and Flemish pictures, but are subordinate to the figures. The first great painter of light and air was the French Claude Lorrain (1600-82), who painted in and near Rome. Although his pictures have classical and scriptural titles, the interest centres in the landscape. The 'Embarkation of the Queen of Sheba' (National Gallery, London), is a fine specimen. The Dutch were early noted for their landscapes. The most famous Dutch landscape painter was Jacob van Ruysdael (1625-82). His 'Bird's Eye View of Haarlem' (Hague) and 'Waterfall' (Dresden) are among his best works. The 'Avenue of Middelharnais' (National Gallery, London), by Meindert Hobbema (1638-1709), is an extraordinary work. The great English line starts with Thomas Gainsborough (1727-88), whose 'Market Cart' (National Gallery, London) shows him at his best, and John Constable (1776-1837), whose 'Hay Wain' and 'Valley Farm' (National Gallery, London) are representative. 'Crossing the Brook' (National Gal-

lery, London) by J. M. W. Turner (1775-1851) is considered one of the greatest landscapes ever painted. Constable greatly influenced the 'Barbizon School' of French painters, who worked in the Forest of Fontainebleau. Famous pictures of this group are 'Dance of the Nymphs' (Louvre) and 'Ville d'Avray' (Metropolitan Museum, New York) by Corot (1796-1875) and 'The Gleaners' (Louvre) and 'Angelus' (privately owned, Paris) by Millet (1814-75). American landscapes of fame are: 'Niagara Falls' (Corcoran, Washington), Frederick Church (1826-1900); 'Sunset in the Woods' (Corcoran, Washington) and 'Delaware Valley' (Metropolitan Museum, New York) George Inness (1825-74); and 'Harp of the Winds' (Metropolitan Museum, New York), by Homer D. Martin (1836-97).

VII. Marines.—The most famous marines are 'The Wave' (Louvre) by Courbet (1819-1878); the 'Raft of the Medusa' (Louvre) by Géricault (1791-1824); 'Fighting Téméraire' (National Gallery, London) by Turner, and the 'Slave Ship' (Museum of Fine Arts, Boston) also by Turner (1775-1851); 'Fog Warning' (Museum of Fine Arts, Boston) by Winslow Homer, (1836-1910); 'The Breaking Wave' by Thomas Moran (Carnegie, Pittsburgh); 'The Wave' (Pennsylvania Academy of Fine Arts, Philadelphia) by Alexander Harrison (1853); 'Roaring Forties' (Metropolitan Museum, New York) by Frederick J. Waugh (1861); and 'Beaching the Boat' (Hispanic Society, New York) by Sorolla (1862).

VIII. Animals and Birds.—Animal painting is ancient. Splendidly drawn animals often appear in Egyptian wall-paintings. The horses of Micon of Athens were famous. Leonardo da Vinci was one of the first Italians to paint horses well. Horses and other animals appear in the pictures of the Adorations of the Magi and Adoration of the Shepherds and the ass occurs in the Flight into Egypt and Christ's Entry into Jerusalem. Early in the 17th century animals began to take a conspicuous place in pictures. Rubens' horses in his Adorations of the Magi are splendidly painted. Rubens also painted camels. Very spirited are his pictures of the chase. Frans Snyders (1579-1657), who studied with Rubens, depicted with skill and vigor wild beasts, domestic animals, dead game and barnyard fowls. He also painted the animals in some of Rubens' works. Snyders took pleasure in representing a fight of animals or birds. In the 17th century the Dutch began to appreciate the beauty of animals grazing in green meadows; and their combination of landscape and animals has never been surpassed. Paul Potter (1625-54) is as great a landscape as an animal painter. His 'Young Bull' (Hague) is the most famous of all animal pictures. His 'Cow Reflected in the Pool' (Hague) is, however, a better work of art. The horses and cattle of Albert Cuyp (1605-91) are superbly executed; and his landscapes are so full of golden glow and misty air that he is called "the Dutch Claude." The 'Promenade' (Louvre) is his most famous work. Mauve (1838-88) specialized on sheep and his many works are of uniform excellence. Nearly every gallery of any size has a cow or cattle by Constant Troyon (1810-65), one of the Barbizon group. His 'Cattle going to

Work' (Louvre) is one of the most popular of all animal pictures. The 'Sheepfold' (Metropolitan Museum, New York), by Charles Jacque (1813-94) is startlingly true to life. The chickens scratching in the straw are as realistic as the sheep. The 'Horse Fair' (Metropolitan Museum, New York) by Rosa Bonheur (1822-99), so full of dash and vigor is known far and wide. Her 'Oxen Ploughing' (Luxembourg) is of equal merit. The European galleries contain fine examples of the great French animal painters, Jean Baptiste Oudry (1686-1745) and François Desportes (1661-1743). George Morland (1763-1804) was famed for his pigs. The subject is not pleasing, but Morland's composition, coloring and technique make his paintings attractive. He is a master of so-called "rustic genre." His works command high prices. The most beloved of all English animal painters is Sir Edwin Landseer (1802-73). 'The Hunted Stag,' 'Alexander and Diogenes,' 'Dignity and Impudence,' 'King Charles Spaniels' and 'Shoeing the Bay Mare' are among other favorites in the National Gallery, London.

Birds have their specialists. They often appear as accessories in early Italian and Flemish masters, particularly the parrot. The great painter of the feathered tribe was Melchior de Hondecoeter (1636-95). He depicted living birds of rare plumage, fowls and dead game. Very famous is his 'Floating Feather' (Rycks) representing a group of chickens, geese and ducks in an attractive landscape. A tiny yellow feather dropped by a young duck floats on the pool. This is so lightly painted that it seems as if a breath would blow it away.

IX. Flowers, Fruits and Still Life.—The Dutch are noted for their flowers, fruits and still life. Jan van Huysam (1682-1749) produced works of great decorative beauty. His flowers are lovely, true to life and are beautifully arranged. Often he makes a *tour de force* by painting a dew drop trickling down a velvet or satin petal. His fruit pieces are equally fine. David De Heem (1570-1632) painted fruit, flowers, plates of oysters, cheese and bread, crystal glasses half full of wine, musical instruments and still life. Rachel Ruysch (1664-1750) was famous for her "flowers." She often paints them growing around a log or lichen-covered stump in the woods, with butterflies hovering around them. For still life, particularly pots and pans, Willem Kalf (1630-93) has never been surpassed, although his pictures are nearly equalled by our American William M. Chase.

X. Architecture.—Artists of the 17th century had a great fancy for painting the ruins of ancient architecture in Rome and its vicinity. The fashion seems to have been set by Claude Lorrain, the French painter, and popularized by Piranesi, the etcher. In the paintings of Gentile Bellini (1427-1507) architecture becomes more than a background for Venetian and Constantinople scenes. Antonio Canal (1697-1768) called Canaletto, made a special study of Venetian architecture. He visited England and painted 'Eton College' (1746), a masterpiece. His pupil, Francesco Guardi (1712-93), almost equals him. His paintings show more color, but are less truthful in details.

The Dutch became famed for their archi-

tectural paintings. The two Hendricks Van Steenwyck, Pieter Neefs (1578-1656) Berckheyde (1630-93) and Emmanuel de Witte (1607-92), represented the interiors of churches with vanishing perspectives and much attention to minute detail and effects of light and deep shadows. The pictures of Jan van der Heyden (1637-1712) give faithful views of Dutch towns, market-places, little houses with "crow-stepped" roofs—all finished in miniature style. More artistic are the works of Pieter de Hooch (1632-81), valuable for interiors and exteriors of comfortable Dutch homes with courtyards arches, red brick tiles and open doors, through which light and air circulate freely. The mosques of Gérôme (1824-1904) are notable triumphs of architectural painting. One of the most striking feats of modern painting has been accomplished by Claude Monet (1840-), who painted a superb series of the façade of Rouen Cathedral under varied atmospheric effects and at different times of day and night.

XI. Genre.—Genre is the name given to a class of painting that represents scenes of ordinary life. Genre pictures are of small size and much studied and finished. The style was carried to perfection by the "Little Masters" of the Low Countries: Ter Borch (1608-81); Metsu (1630-67); Ver Meer of Delft (1632-75); Pieter de Hooch (1630-81); Jan Steen (1626-79); Teniers (1610-94); Ostade (1610-85); Frans Mieris (1635-81); Gerard Dou (1610-75); and other Dutch and Flemish painters. People sitting in a courtyard or in a well-furnished room enjoying a meal, or singing to lutes; a lady taking a music lesson; a doctor calling on a patient; a lady dressing before her toilet table; an officer bidding farewell to his love; a messenger delivering a letter; a card-party; an oyster supper; a cavalier drinking with friends; an old woman peeling apples; a butcher's shop; a kitchen; a village fair, or *kermesse*; a company of merry-makers at an inn; a family giving and receiving presents on Saint Nicholas day; a boy blowing soap bubbles; a girl opening a window; and skating scenes were all materials for the painters of *genre*.

In these pictures all the details of furniture, glass, china, household articles, fruit, flowers, food and musical instruments are rendered with minute care. The costumes of the 17th century—velvets, satins, lace-collars, fur-trimmed sacs, jewels and plumed hats are marvelously reproduced. Ter Borch's 'Satin Gown,' also called 'Parental Advice' (Rycks), is one of the most remarkable exhibitions of texture ever seen on canvas. Another 'Lady in White Satin' (Dresden), by Ter Borch, is almost its equal. Ter Borch's 'Music Lesson' (Louvre) and 'Officer with a Letter' (Dresden) are famous also. Other celebrated genre pictures are: Jan Steen's 'Merry Home Coming' (Rycks); 'Feast of Saint Nicholas Day' (Rycks); 'Parrot's Cage' (Rycks); 'Quack Doctor' (Rycks); 'Dancing Lesson' (Rycks); Dou's 'Dropsical Woman' (Louvre) and 'Woman with a Pitcher' (Metropolitan Museum, New York), by VerMeer of Delft. The 'Card-Players' (Dresden), by Caravaggio (1569-1669) would be classed as genre if it were not so large. Other works depicting scenes of everyday life but which cannot be called *genre* because of

their size are: 'Marriage à la Mode' (National Gallery, London), by Hogarth; 'Bénédictine' or the 'Benediction' (Louvre), by Chardin (1699-1779); 'L'accordée de Village' (Louvre) by Greuze (1725-1805); the 'Huguenot Lovers' (privately owned), Sir John Millais (1829-96); 'Spanish Marriage' (Metropolitan Museum, New York), Fortuny (1838-74); and 'Duel after the Masquerade' (Chantilly and replica Walters Gallery, Baltimore) Gérôme (1824-1904).

XII. Mythological and Fanciful.—Some of the most beautiful pictures represent mythological, allegorical or fanciful subjects. In this class are Botticelli's 'Venus' (Uffizi) and 'Spring' or 'Primavera' (Academy, Florence); Raphael's 'Triumph of Galatea' (Farnesina, Rome); Guido Reni's 'Aurora' (Rospigliosi Palace, Rome); 'Parnassus' (Louvre), Andrea Mantegna (1431-1506); 'Sleeping Venus' (Dresden), Giorgione (1478-1510), Titian's 'Bacchus and Ariadne' (National Gallery, London); Veronese's 'Rape of Europa' (Doge's Palace, Venice); Veronese's 'Vision of Saint Helena' (National Gallery, London); 'Embarkation for Cytheria' (Louvre), Watteau (1684-1721); the 'Cruche cassée' (Louvre), Greuze (1725-1805); 'Jeanne d'Arc' (Metropolitan Museum, New York), Bastien Le Page (1850-84); Correggio's 'Reading Magdalen' (Dresden); 'Saint Genevieve Marked with the Divine Seal' (Panthéon, Paris) Puvis de Chavannes (1824-98); and the 'Mirror of Venus' (privately owned), Sir Edward Burne-Jones (1833-98).

ESTHER SINGLETON,

Author of 'Famous Paintings,' etc.

PAIRING, in legislative and other assemblies, a practice by which two members belonging to opposite parties or factions agree that both shall be absent for a specified time, or that both shall abstain from voting on a particular question. Thus a vote is nullified on each side. The terms pairs and pairing-off are also frequently used.

PAIS, pā'ēs, **Ettore**, Italian archæologist: b. Borgo San Dalmazzo, 1856. Pais was elected director of the Museo Nazionali di Naples and also member of the Royal Academy of that city. His numerous archæological publications include 'Storia di Roma' (1898); 'Il riordinamento del museo nazionali di Napoli' (1902); 'Perchè fui esonerato dalla direzione del museo nazionali di Napoli?' (1905); 'Ancient Legends of Roman History,' translated by M. E. Cosenza (1905); 'Ricerche storiche e geografiche sull'Italia antica' (1908; English translation entitled 'Ancient Italy: Historical and Geographical Investigations,' by C. D. Curtis, 1908); 'Storia critica di Roma durante i primi cinque secoli' (1913).

PAISH, pāsh, **SIR George**, English economist: b. 1867. In 1881-88 Paish served as secretary to the editor of the *Statist*; from 1888 to 1894 was sub-editor, and from 1894 to 1900 assistant editor of that journal. After 1900 he was joint editor. He is a governor of the London School of Economics and member of the departmental committee of the Board of Trade on Railway Accounts and Statistics in 1906-08. He has also served as adviser to the Chancellor of the Exchequer and the British Treas-

ury on financial and economic questions in 1914-15. Paish was knighted in 1912. He visited the United States during the Great War of 1914-18 in connection with international financial arrangements incident to the great conflict. His publications include 'British Railway Position' (1902); 'Railways of Great Britain' (1904); 'Railroads of the United States' (1913); 'Capital Investments in Other Lands' (1909; 1910); 'Savings and Social Welfare' (1911).

PAISIELLO, pǎ'ē-zyě'lō, or **PÆSIELLO**, Giovanni, Italian composer: b. Taranto, 9 May 1741; d. Naples, 5 June 1816. After having received his musical education in the conservatory of Saint Onofrio at Naples in 1776 he went to Saint Petersburg, where he produced the opera 'Il Barbiere di Siviglia.' After remaining at Saint Petersburg for eight years he returned to Naples by way of Vienna, where he composed 12 symphonies for large orchestra, and wrote the opera 'In Re Teodoro.' In Naples he remained for 13 or 14 years, from 1785 to 1799, and during this time he composed some of the operas which were produced at the Neapolitan Theatre, and he was also made chapel master to Ferdinand IV. In 1802 he went to Paris to organize the music of the chapel of Napoleon, and while there excited much jealousy, but it was not until 1804, when his opera 'Proserpine' had been produced and proved a failure, that he returned to Naples. Paisiello produced between 95 and 100 operas, besides 100 masses, requiems, etc. Among the most prominent of his operas may be mentioned 'Dal finto al vero,' composed in 1777; 'Il Marchese di Tulipano'; 'Nina, o la Pazza d'Amore'; 'La Molinara.'

PAISLEY, pǎz'li, Scotland, a manufacturing town of Renfrewshire, on the White Cart, about three miles above its confluence with the Clyde and seven miles west-southwest of Glasgow. It consists of an old town on the west or left and a new town on the east or right bank of the river, communicating by three handsome bridges. The most noteworthy building is the restored Abbey Church of a monastery founded in 1164 by Walter, son of Alan, the first of the house of the Stewarts. Other noteworthy edifice are the new county buildings; the old county buildings and prison, a quadrangular pile in the castellated style; the town-hall, an imposing building in the classical style; the Neilson educational institution; the buildings containing the free library and museum; the Coats Observatory and the Coats Memorial Church (Baptist). The city has several parks and owns a great part of its public utilities and workmen's houses. Paisley has been long noted for its manufactures, especially of textile goods. The shawl manufacture, introduced about the beginning of the present century, and long a flourishing industry, is not now a staple, but the textile manufacture is still large, though the chief industry is that of sewing cotton, for which Paisley is celebrated all over the world. Wilson, the ornithologist, the poet Tannahill, and Professor Wilson (Christopher North) were natives of Paisley, which possesses a bronze statue of the ornithologist and of the poet. Paisley, the mediæval *Passeleth*, is a town of ancient origin, having been at one time a Roman station under the name of *Vandurara*. Pop.

84,499. Consult Brown, 'History of Paisley' (Paisley 1886).

PÄIVÄRINTA, pǎ'ē-vǎ-rěn'ta, Pietari, Finnish author: b. 1827; d. 1913. Coming of a poor family, his early years were passed in a hard struggle to secure a competence and a position of influence. He was successful and for nine years sat in Parliament. His first work was a description of the social life of his country in the martial period of Charles XII entitled 'Seurahunnan kosto,' which was followed by intimate descriptions of Finnish peasant life. Some of his shorter works have appeared in Swedish in the collection 'Bilder ur Lifvet,' while others have been translated into German, Norwegian, Flemish and Russian.

PAIXHANS, pěk'sǎn', Henri Joseph, noted French general: b. Metz, 22 Jan. 1783; d. Jouy-aux-Arches, 20 Aug. 1854. He entered the artillery after being graduated at the École Polytechnique, fought under the empire with great bravery, especially at the siege of Paris in 1814, and in 1848 became division commander. From 1830 to 1848 he was a member of the House of Deputies. Paixhans invented a howitzer called by his name, which carried a hollow shot and cylindrical, conically pointed shells, also of his invention. During the Crimean War he investigated the concealment of floating batteries. He wrote several valuable studies of army and navy ordnance.

PAIXHANS GUN. See **ORDNANCE**.

PAJOU, pǎ'zhoō, Augustin, French sculptor: b. Paris, 19 Sept. 1730; d. there, 8 May 1809. He became a pupil of Lemoine and won the Prix de Rome in 1748, after which he studied for 12 years at Rome. Upon his return he was elected to the Academy and was employed by Louis XVI to make statues of Buffon, Descartes, Pascal, Bossuet and Turenne. In the Louvre may be seen 'Pluto Holding Cerebus in Chains,' 'Psyche,' and a bust of Madame du Barry, together with other works executed by him. The sculptures of the Salle de l'Opéra at Versailles and the ornaments of the cathedral of Orleans and of the Palais Bourbon are typical samples of his work.

PAKAWA, pǎ-kā-wǎ'. See **PINTO**.

PAKENHAM, pāk'en-am, Sir Edward Michael, British soldier: b. County Westmeath, Ireland, 19 March 1778; d. near New Orleans, La., 8 Jan. 1815. He was a lieutenant in the British army in 1794 and served with distinction under his brother-in-law, the Duke of Wellington, in the Peninsular and French campaigns. He rose to the rank of major-general in 1812. In 1814, after the death of General Ross at Baltimore, he was appointed to the command of the British forces there. He led the expedition against New Orleans, where his forces were defeated by General Jackson and was killed in battle 8 Jan. 1815. See **NEW ORLEANS, BATTLE OF**.

PAKHOI, pāk-hoi', China, treaty port in the province of Kwang Tung, on the Gulf of Tong King, 275 miles south by west of Canton. There are Chinese and European sections, the latter built on the top of a high bluff. There is an extensive export trade in anise oil, indigo, fish, hides, etc., and imports of cottons and woolens, opium and petroleum. Its history as a

treaty port dates from 1876. In normal years the imports average about \$13,000,000 in value, with exports aggregating about \$700,000. Pop 20,000.

PALACIO VALDÉS, pa-lä'thē-ō val'däs, Armando, Spanish novelist: b. Entralgo, Asturias, 4 Oct. 1853. He was educated at Oviedo and at Madrid, devoting especial attention to the studies of jurisprudence and political economy. His first literary efforts appeared in *La Revista Europea*, in the form of sparkling essays, which were so popular that the author became editor of the *Revista* in 1875. He directed the fortunes of this review until 1878, after which he confined his efforts to fiction. In 1881 he brought out 'El señorito Octavio,' which betrayed the author's powers of character analysis and delineation and also his descriptive powers. It was followed in 1883 by 'Marta y Maria,' the author's masterpiece, and a splendid portrayal of the struggle of a soul in choosing between a spiritual and contemplative life and an earthly love. Meanwhile several critical works had appeared from our author's pen, of which the chief are 'Los oradores del Ateneo' (1878); 'Los novelistas españoles' (1878); 'Nuevo viaje al Parnaso' and 'La literatura en 1831' (1882). In 1884 Palacio Valdés published 'El Idilio de un enfermo,' which is a most interesting autobiography. 'José' appeared in 1885 and is one of the best tales in Spanish of those dealing with life on the sea. Other works appearing in rapid succession were 'Riverita' (1886); 'Maximina' (1887); 'La Hermana San Sulpicio' (1889); 'El quarto poder,' dealing with journalistic life (1888). In 1892 appeared 'La espuma' and 'La Fe,' which, although very popular abroad, were execrated in Spain, the former being construed as an attack on the aristocracy and the latter on the Catholic Church. Other works more after the author's early style followed, including 'El maestrante'; 'El origen del pensamiento'; 'Los Majos de Cádiz' (1896); 'La alegría del capitán Ribot' (1899); 'Tristán, ó el pesimismo' (1906). Consult Blanco-García, 'La literatura española en el siglo XIX' (pt. II, 2d ed., Madrid 1903); Baxter, 'A Great Modern Spaniard' (in *The Atlantic Monthly*, Boston 1900); Davidson's introduction to his translation of 'José' (ib. 1900); Howells, W. D. (in *Harper's Magazine*, New York 1886).

PALACKY, pä-lats'kē, Frantisek, Bohemian philologist, critic and historian: b. Hodslavitz, Moravia, 14 June 1798; d. Prague, 26 May 1876. He studied philology and history at Presburg and Vienna, and in 1831 was appointed historiographer to the states of Bohemia. In the compilation of a general history of Bohemia, he searched libraries and archives in Bohemia and in Germany and Italy. In the political agitation of 1848 Palacky was the leader of the Slav or national party, as opposed to the German. His great work is his 'History of Bohemia' (in German and Bohemian, 5 vols., Prague, 1836-67). It has high repute for conscientiousness, thoroughness and accuracy. Among his many other works is one on the most ancient monuments of the Czech tongue, and in 1872 his 'Political Testament'; 'Geschichte des Hussitentums' (1868), and 'Geschichte des Hussitenkriegs' (1872-74). "Father Palacky," as he was fondly called,

though himself a Protestant, was regarded by Roman Catholics generally with perfect confidence, even with veneration. He persistently but vainly opposed the reconstruction of Austria on a German-Hungarian basis, and in 1861 when he was elected into the Austrian House of Lords, he declined to attend.

PALÆOBOTANY. See PALEOBOTANY.

PALÆOGEOGRAPHY. See PALEOGEOGRAPHY.

PALÆOGRAPHY. See PALEOGRAPHY.

PALÆOLOGUS, a Byzantine family name which first became prominent about the middle of the 11th century, when a George Palæologus is reported as a prominent supporter of the Nicephorus Botaniates. The family reached the imperial throne in 1260 in the person of Michael VIII. This emperor successfully undertook many expeditions to Greece and the Archipelago, and used in vain his utmost endeavors to heal the schism between the Roman and Greek churches. His successor on the throne was his son, Andronicus II (reigned 1282-1328), under whose reign the Turks commenced in earnest a series of assaults on the Byzantine dominions. Andronicus attempted to oppose them with a force composed of mercenaries, but with small success, as these troops, with perfect impartiality, attacked both his enemies and his subjects. To pay them, he was compelled to levy such imposts as nearly destroyed Byzantine commerce. He associated his son, Michael IX, with himself in the government, and was dethroned by his grandson, Andronicus III (reigned 1328-41), an able warrior and wise ruler. He won several victories over the Bulgarians, the Tatars of the Golden Horde and the Serbians, and diminished the oppressive imposts of the previous reign. He failed, however, in his expeditions against the Catalans and the Turks made various forays extending even to the Balkans and Thrace. By his subjects he was affectionately called "Father of his Country." His son, John VI (reigned 1355-91), a weak and voluptuous prince, attempted in vain both by force and bribery to stop the progress of the Turks; at last the Pope, moved by his urgent entreaties, backed by a promise to submit the Greek Church to the Pope's supremacy, urged the Hungarians and Serbians to arm in defense of the Greek emperor, but the result was only an additional triumph to Sultan Amurath. The imbecile emperor was several times deposed, and, on his final reinstatement by the sultan, acknowledged himself as his vassal for the capital and a small tract along the Propontis and Black Sea. Indeed, so degraded had the Byzantines become, that they obeyed the Sultan Bajazet's summons to aid him in reducing Philadelphia, the last Greek stronghold in Asia Minor. His son, Andronicus IV (reigned 1355-73), who had been associated with him in the government, died in exile. Manuel II (reigned 1391-1425) pursued the same tactics as his father, John VI, and with the same result. The allied army of the Hungarians, Germans and French, which he had summoned to his aid against the Turks, was totally routed at Nicopolis by Bajazet, and Constantinople itself closely besieged. The invasion of Asia Minor by Timur, however, compelled the sultan to withdraw his whole force;

and his subsequent defeat and capture at Anagora in 1402, and the contests among his sons for the supremacy, gave the Greek empire a breathing space. Having aided Mohammed I in his contests with his brothers, Manuel was, by the grateful sultan, presented with some districts in Greece, Thessalonica and on the Euxine. John VII (reigned 1425-49), was pressed by the Turks and urgently besought the Pope for aid from the West, promising to use his influence in bringing about a union of the Greek and Latin churches under the primacy of Peter. To this end he journeyed to the Council of Florence, where in July 1439, the union of the churches was agreed to. The agreement, however, was rendered null by the opposition of the clergy and people of the East. The Pope, however, saw that it was for his interest to fulfil his part of the agreement, and accordingly persuaded Wladislas of Hungary to lead his forces against the Turks, but this only hastened the downfall of the Palæologi. John's brother, Constantine XIII (reigned 1449-53), heroic scion of a degenerate race, accepted the crown, after much hesitation, knowing his total inability to withstand the Turks, and even then took the precaution of obtaining the sultan's consent before he exercised the imperial authority; but some rebellions in Caramania baffling Sultan Mohammed II's efforts to quell them, the emperor was willingly persuaded by his rash advisers that the time had now arrived for rendering himself independent of the Turks. The attempt brought swifter destruction on the wretched remnant of the Byzantine empire, for Mohammed invested the capital by sea and land, and after a siege, lasting from 6 April to 29 May 1453, Constantinople was taken by storm and the last of the Palæologi fell fighting bravely in the breach. A branch of the family ruled Montferrat, Italy, from 1306 to 1533. The Palæologi had married into the ruling houses of Hungary, Serbia and a niece of Constantine XIII married Ivan, Tsar of Russia. This marriage was advanced repeatedly by subsequent tsars of Russia as the basis of their claim to European Turkey. Consult Gibbon, Edward, 'Decline and Fall of the Roman Empire,' edited by J. B. Bury (New York 1898-1900), and Pears, Edwin, 'The Destruction of the Greek Empire' (ib. 1903).

PALÆONTOLOGY. See PALEONTOLOGY.

PALÆOZOIC. See PALEOZOIC.

PALÆPHATUS, Greek mythographer. The period in which he flourished is uncertain, but there are many references to him as the author of a large work dealing with the Greek myths for which he furnished explanations either historical or allegorical in character. Of this work there remains to us only a synopsis called 'περὶ Ἀπίστων' (On Incredible Things), which for centuries was a favorite text in schools. For the text consult Westermann, 'Mythographi Græci' (Brunswick 1843), and Festa, N., 'Mythographi Græci' (Vol. III, Leipzig 1902). Consult also Wipprecht, F., 'Quæstiones Palæphatæ' (Leipzig 1892).

PALÆSTRA (Greek, "wrestling-school"), originally a school for the training of Greek youth in gymnastic exercises. At first private, such schools were afterward supported by the state, and in the most comprehensive sense a

palæstra was a public place set apart, and under official direction, for exercises in wrestling and various forms of athletics. In these schools or gymnasiums special privileges were given to athletes training for contests in the public games. The name palæstra is also applied to wrestling and athletics themselves.

PALAFox Y MELZI, pā'la-fōn' ē mal'-thē, DON José de, dōn hō-sā' dā, DUKE OF SARAGOSSA, Spanish patriot: b. Aragon, 1780; d. Paris, France, 16 Feb. 1847. When very young he was appointed an officer of the royal body-guard and in that capacity accompanied Ferdinand VII to Bayonne in 1808. Palafox escaped the capture which befell his royal master and fled to Saragossa which he defended as captain-general of Aragon in two sieges in 1808-09, but was captured by the French and imprisoned (1809-13) at Vincennes. He then returned with the king to Spain, and was confirmed as captain-general of Aragon. Later he turned against Ferdinand VII and in 1833 joined the forces of Queen Isabella. He was created Duke of Saragossa in 1836.

PALAIHNIHAN, pa-lih'nī-hān, or **PIT RIVER INDIANS**, an American family of Shastan stock comprising numerous tribes living in the northeastern part of California, in the basin of the Pit River, hence the local or common name of Pit River Indians (q.v.). Seven distinct tribes of these people were known in the days of 1849, but they are now almost extinct. They are of a low type of the American aborigines. Consult Dixon, R. B., in *American Anthropologist*, n. s., Vol. VII (Lancaster, Pa., 1905).

PALAIS DE JUSTICE, pā'lā dē zhūs'tēs, (French, palace of justice), a French courthouse, more specifically, the courthouse of Paris. Rouen also contains an edifice which is a remarkable example of the Flamboyant style of Gothic. See FRENCH ARCHITECTURE; PARIS; BRUSSELS.

PALAIS ROYAL, pā-lā rwā-yāl, a collection of buildings in the Rue Richelieu in Paris, composed of a palace, public gardens, shops, cafés and restaurants. The palace was built in 1634. (See PARIS). It was built for Cardinal Richelieu in 1629-36 by Lemercier. He bequeathed it to Louis XIII. It later became the residence of the Orléans Bourbons. Here Napoleon installed the Tribunal. At the Restoration it was repurchased by the Duke of Orléans. He formed the Cours de Nemours and built the Galerie d'Orléans. At the Revolution of 1848 the Palais Royal was appropriated as the domain of the state and called the Palais National. On 23 May 1871, during the struggle between the army of Versailles and the Communists, it was set on fire. The left wing and part of the central pavilion were destroyed, but the galleries and the Théâtre Français were preserved. The destroyed wing has been rebuilt and other portions of the palace have also been restored. The Théâtre Français and the Théâtre du Palais Royal form part of the buildings.

PALAMEDES, pāl-a-mé'dēs, in Greek mythology, a hero, the son of Nauplius and Clymene. Although figuring prominently in the later accounts of the Trojan War, he is not referred to in the Homeric writings. Having discovered

that the madness of Odysseus was only feigned, and having brought him to the leaders before Troy, Palamedes is said to have become an object of hate to that hero. Odysseus smuggled into the tent of Palamedes a letter from Priam and then had him stoned to death for treason. His father in turn shipwrecked the Greeks on the promontory of Caphareus by false lights. He is represented as skilled in learning, and his name is connected with the invention of letters, numbers, money, weights and measures, checkers, the lighthouse and dice.

PALAMON AND ARCITE, Theban princes, who both loved Emilia, sister of Hippolyta, and were imprisoned by Theseus. Boccaccio narrates their history in the 'Teseide,' which was used by Chaucer for 'The Knight's Tale.' In 1487 appeared Anne de Greville's poem in French, 'Palamon and Arcite,' and in 1634 Fletcher's 'Two Noble Kinsmen' dealt with the same theme. There were two plays, now lost, dealing with this story, one by Edwardes, produced for Elizabeth at Oxford in 1566, and one mentioned by Henslowe as performed in 1594. The story is also told by Dryden in 'Fables' (1700).

PALANAN, pā-lā'nān, Philippines, a pueblo of the province of Isabela, Luzon, on a river, five miles from the Pacific Coast, at the foot of the Sierra Madre Mountains, 36 miles east of Ilagan. A mountain trail begins at this point and Palanan is the trade centre for the surrounding region. It was here that Aguinaldo was located and captured. Pop. 1,140.

PALANDER AF VEGA, pā-lān'dēr äv vā'gā, Adolf Arnold Louis, Swedish naval officer and explorer: b. Karlskrona, 1842. In 1868 he was with the Nordenskjöld expedition to Spitzbergen and was again a member of the expedition of 1872-73. In 1878-79 Palander was navigator of the *Vega* in the search for the Northeast Passage. He was awarded a pension by the Riksdag; was made aide-de-camp of Oscar II; created a knight and also made an admiral. He was Minister of State in 1901-05 and published an account of his search for the Northeast Passage.

PALANPUR, pā-lān-poor', **PAHLANPUR**, or **PAHLUMPUR**, native state of India in the province of Gujarat, Bombay division, south of Rajputana. The state is crossed by the Rajputana-Malwa Railway, on which the town of Palanpur, capital of the district, is a junction for the British cantonment of Deesa. The native state has an area of 1,766 square miles and population of about 222,627. A political agency including this and other surrounding states contains 6,393 square miles and has a population of 467,691. The town, with a population of about 17,799, like the state and the agency, suffered terribly from plague, so that the population has decreased enormously.

PALANQUIN, pāl-ān-ēn, **PALANKEEN**, or **PALKI**, a vehicle commonly used in India and Oriental countries. It is a sort of litter or covered carriage, borne on the shoulders of four porters, eight of whom are attached to it and who relieve each other. It is usually provided with a bed and cushions, and a curtain, which can be dropped when the occupant is disposed to sleep.

PALATE, the roof and the superior aspect of the mouth or oral cavity toward its hinder or posterior portions. Anatomists are accustomed to speak of the hard and the soft palate. The former is constituted by the palate and superior maxillary bones; the latter is the more or less mobile prolongation of the hinder part of the roof or lining membrane of the mouth which is attached to the posterior border of the hard palate. The hard palate supports the tongue when that organ is employed in tasting, in the production of articulate sounds, in mastication and in swallowing. The membranes and tissues which cover the bones forming the hard palate are of thick conformation and are closely bound to the surface of the bones. The tissues are thinner toward the middle line of the palate or raphe. The palatine glands exist in a row on each side of the hard palate and are most numerous and of larger size as the hard palate is continued backward to form the soft palate. The mucous membrane of the hard palate is of a whitish color, this appearance being produced by a thick layer of epithelial cells covering the membrane.

The soft palate exists only in the crocodiles out of the class *Mammalia*. In the *Cetacea* it forms a muscular canal, which prolongs the hinder nostrils downward and backward, and is thus adapted to the breathing-process of these aquatic forms. In the ant-eaters the soft palate is nearly eight inches in length. It consists in all of mucous membrane and muscles and forms a semi-partition between the mouth and the hinder nostrils. In front it is attached to the hard palate. Behind it is free, and in the middle a pointed process, the uvula, is situated. This is found fully developed only in man and the apes. Its upper surface, or that next the nasal passages, is convex and is prolonged to form the floor of the nose. The lower or under surface is concave, so as to adapt it to receive the back of the tongue; and on this surface the soft palate bears a median ridge, showing the early stage of its formation, when it consists of two halves. Non-union of these halves and of those of the hard palate produce the deformity known as cleft palate. This is likely to interfere with nutrition in the child and with articulation, and may be complicated by harelip. It can and should be remedied by operation in early infancy. Mucous glands are abundantly distributed in the membrane forming the soft palate, these structures secreting the mucus which serves to lubricate the throat during the passage of food. Above these glands muscular tissue is found and the upper surface is formed of mucous membrane of the nasal passages already alluded to. The uvula, depending in the middle of the soft palate, gives to the latter the appearance of a divided or double arch. This structure, the uses of which are undetermined, consists of numerous mucous glands and a muscle known as the azygos uvulae. The uvula varies in length in different subjects and at different times in the same person. Its permanent elongation gives rise to an irritant cough produced by its tickling the throat, and for the relief of this complaint its lower border is frequently excised.

In front the soft palate becomes continuous with the tongue and pharynx or back part of the mouth through two mucous and muscular folds

on either side known as the anterior and posterior pillars of the fauces. The anterior arch of each side exists as a curve from the uvula to the side of the tongue. The posterior arch begins at the uvula, follows the free edge of the soft palate and ends at the side of the pharynx. The pillars of each side separate or diverge in a triangular manner from their point of origin and within the triangle of each side a tonsil is contained.

The muscles of the soft palate number five pairs. These are the levatores palati, which raise the soft palate and bring it to the horizontal position in swallowing. The *tensores palati* draw the soft palate downward and tighten it, and their action also includes the keeping patent and open of the Eustachian tube. The *palatoglossi* and *palato-pharyngei* muscles form the bulk of the arches of the soft palate; and the *azygos uvulae* muscle constitutes the last structure of this description included in the soft palate. The tonsils or *amygdalæ* ("almond-like") are placed between the palatine arches. The substance of each tonsil contains numerous follicles, which open externally by 12 or 15 openings, and more deeply placed are masses of adenoid or lymphatic tissue similar to the Peyer's patches (q.v.) of the intestine. The tonsils are liable to hypertrophy and inflammatory affections, and are excised for disease without leaving any bad effects. Enlarged tonsils may obstruct the breathing and may produce deafness by occlusion of the Eustachian tube. (See *TONSILITIS*). Both the hard and soft palate are supplied with blood by the descending palatine branch of the internal maxillary artery, and with nerves by the palatine branches of the superior maxillary nerve. The use of the soft palate is chiefly to close the posterior nares or nostrils and so to prevent the escape of the food by the nose in swallowing; during which process the palate is elevated by the levator muscles from its usually dependent position to the horizontal position. In the latter position it lies upon the back of the pharynx and so closes the nares. The arches of the palate assist in swallowing. The anterior arches during deglutition contract, so as to prevent the food from returning into the mouth; while the posterior arches contract at the sides and so preclude the escape of food into the nose. The whole process of swallowing is performed firstly by the mass of food being brought to the back of the tongue. The lower jaw being next closed to afford a fixed point for the action of the muscles which raise the larynx, the food is sent into the elevated pharynx by the pressure of the tongue on the palate. The posterior palatine arches and soft palate prevent the escape of the food into the nose at this stage; the anterior palatine arches and tongue prevent it returning to the mouth; the epiglottis is shut over the upper opening of the larynx so as to prevent the food entering the windpipe; and by the action of the constrictor muscles of the pharynx the food is finally shot into the œsophagus or gullet, along which tube it is propelled to the stomach by the peristaltic contraction of its muscular walls. See *MOUTH*; *NOSE AND THROAT*; *PHARYNX*; *TONGUE*.

PALATINATE, *The*, (1) a comprehensive term for two states of the German Empire, which, until 1620, were united. The name Pala-

tinate (German, *Pfalz*) was originally given to the imperial castles dispersed over the German Empire, in which the emperors resided alternately, with a view to maintain order by their presence and to administer justice impartially in all the provinces of the empire. The palatine or count palatine was the highest civil and judicial officer in these castles. Finally, the title was retained by only two of the territorial magnates of the empire, whose states were distinguished as the Upper and Lower Palatinate, or as the Palatinates of Bavaria and the Rhine. The Upper Palatinate was included in the circle of Bavaria and was bounded north by the county of Baireuth, east by Bohemia, south by the county of Neuburg, west by Bavaria and the territory of Nuremberg. Its capital was Amberg. The Lower Palatinate (Palatinate of the Rhine) was contained in the electoral circle of the Rhine and was situated on both sides of the river. It was bounded by the territories of Mainz, Katzenellenbogen, Württemberg, Baden, Alsace, Lorraine and Trèves. It was composed of the Palatinate proper or Electoral Palatinate on the right bank of the Rhine, one of the most fertile countries in Europe, and of the principality of Simmern, the duchy of Deux-Ponts (Zweibrücken), the half of the county of Spannheim and the principalities of Veldenz and Lautern. The counts-palatine of the Rhine, whose original seat was Aix-la-Chapelle, in the 11th century were already in possession of the office and of the lands pertaining to it, and were among the most powerful princes of the German Empire. In 1227 the entire Palatinate fell into the possession of the house of Bavaria and underwent a series of successions until 1619 when Frederick V, of the Simmern line, who had succeeded in 1610, was put to the ban of the empire for aspiring to the crown of Bohemia. (See *GERMANY*; *THIRTY YEARS' WAR*). His electorate and estates were given in 1623 to Maximilian, Duke of Bavaria. Charles Louis, son of Frederick V, recovered the Lower Palatinate by the Peace of Westphalia (1648), and a new electorate, the eighth, was created for him, with the office of high-treasurer. The Upper Palatinate and the former rank of the elector-palatine in the electoral college remained with Bavaria. In 1742 the electorate fell to the Sulzbach line, represented by Karl Theodor, and in 1777 he succeeded to the electorate of Bavaria, a portion of the estates of which, however, fell to Austria. This was accompanied by the recovery of the old electoral office of the Palatinate and the transference of the grand-treasurership to Brunswick. Toward the close of his reign the Palatinate was conquered by the French. He died without issue in 1799 and was succeeded by Maximilian Joseph, Duke of Zweibrücken. At the Peace of Lunéville (1801) he was compelled to surrender the Palatinate. The possessions on the left bank of the Rhine were annexed to France, a considerable part of the remainder was given to the Grand-Duke of Baden and the rest was distributed among other princes. At the Peace of 1814 the German states recovered their possessions on the left bank of the Rhine and the Palatinate was redistributed among Bavaria, Baden, Hesse-Darmstadt and Prussia. The portion belonging to Baden is included in the circles of Mannheim, Heidelberg and Mosbach; the Darmstadt

portion constitutes the provinces of Starkenburg and Rheinhessen. Bavaria received the whole of the Upper Palatinate and the portion of the Lower Palatinate forming the Bavarian circle of Rhenipfalz. The Prussian portion was added to the Prussian province of Rheinland. The area of the Rhenish Palatinate is 2,372 square miles (pop. 937,085); of the Upper Palatinate, together with Regensburg, which is joined to it into one province, is 3,862 square miles (pop. 1,600,284). Speyer is the capital of the Rhenish Palatinate, Regensburg that of the Upper Palatinate. The population of Speyer is about 23,000. Consult Nebenius, 'Geschichte der Pfalz' (Heidelberg 1874).

(2) The term palatinate or county palatine came into use in England during the 13th century, the counts or earls-palatine ruling over entire counties, acting as independent princes, exacting feudal rights and contributions and simply swearing homage and fealty to the king. The principal counties palatine were Lancaster, Chester and Durham. In the colonial days of the United States Maryland was granted to the Baltimore family as a county palatine on the model of Durham.

PALATINE ANTHOLOGY, a Greek anthology compiled in the 10th century by Constantine Cephalas. For several centuries it was lost but in 1606 Salmasius found it in the Palatine Library, Heidelberg. It was first published in Brunnck's 'Analecta' (1776). Consult Thackeray, 'Anthologia Græca' (London 1877).

PALATINE HILL (Lat. *Palatium*, later *Mons Palatinus*), the most central, the earliest settled and (save for the Capitoline) the most famous and important of the seven hills of Rome. About 130 feet above the Tiber and 36 more above the sea-level, the hill is an irregular quadrilateral and to this shape is due the name of the *Roma quadrata*, the primitive city which the legend attributes to Romulus. The name Palatium, which the Romans connected with the Arcadian city Pallantium, is probably related with Pales, an Italian rural divinity. On the Palatine the Lupercalia was celebrated in honor of Romulus; there were the ancient temples (of Victory, Jupiter Stator and the Magna Mater) in the days of the early republic, the residences of Cicero, Marcus Scaurus and others in the last period of the republic and at the beginning of the principate Augustus' own home (to which fact the use of the word "palace" from the *Palatium* is due), the temple of Apollo dedicated in 28 B.C. and the Latin and Greek library. Tiberius and Caligula built additions to Augustus' palace; the latter emperor bridged the Capitoline to the Palatine. The Palatine was no longer used as an imperial residence after the time of Alexander Severus and there was no more splendid building there until Pope Paul III built the villa called Orti Farnesiani. Excavations of the hill began in 1762 under Bianchi's superintendence and was renewed a century later by Rosa at the expense of Napoleon III. The Italian government purchased the Farnese Gardens in 1871 and now has charge of excavations.

PALATKA, pa-lăt'ka, Fla., city, county-seat of Putnam County, on the Saint John's River, and on the Florida East Coast, the Florida Southern, the Georgia Southern and Florida and the Jacksonville Atlantic Coast Line rail-

roads, 47 miles in direct line south of Jacksonville. It is the centre of a prosperous agricultural and fruit region, is in daily steamer communication with Jacksonville and exports large quantities of oranges, sugar, cotton and cypress lumber. It is also popular as a winter resort. It is the seat of the Putnam County High School and of the Saint Joseph's Academy and Day School (Roman Catholic). Pop. 5,102.

PALAWAN, pä-lä'wän, Philippines, the most southwestern island of the archipelago, lying west of Mindoro, Panay and Negros; it is bounded on the west by the China Sea, which it separates from the Sulu or Mindoro Sea; area, 4,027 square miles; with dependent islands, 5,238 square miles. It is one of the largest islands of the Philippines, and from its geographical position one of the most important, as it lies in the trade route between India and China and Manila.

Topography and Climate.—The island is long and narrow in shape; the greatest length from northeast to southwest is 278 miles, and the width averages only 17 miles, and is nowhere more than 30 miles, being only 4½ miles in the centre. The coast is indented with numerous sounds, gulfs and bays, most important among them Malampaya Sound (q.v.). A mountain system which divides Palawan into two watersheds extends the length of the island following the general direction of the coast; the highest summit of this system is Manta-lingajan in the south (6,843 feet); the average height is from 2,500 to 3,000 feet; between the summits are high table-lands. There are a number of rivers, which are all short; in the northern part there is a lake which opens into the ocean by a subterranean river. The climatology of the island shows two seasons, the southwest monsoon or wet season and the northeast monsoon or dry season; the heat is not extreme; malarial fevers are common on some parts of the coast. Earthquakes are relatively rare.

Forests and Fauna.—The mountains are very heavily wooded, the forests contain valuable building, dye and medicinal woods, including ebony, sandal, logwood, bamboo, ipil (a very hard wood), apiay, camphor, gum mastic, molave; a number of the trees found in Palawan exist nowhere else in the Philippines. Dammar, a gum which exudes from a large tree, is found in many places in deposits in the earth, which have, however, never been fully worked. The nipa palm grows luxuriantly along the rivers, and rattan is an important article of export. There are also numerous plants of varied character, including orchids and pitcher plants; among the latter is a trailing variety, the pitchers of which will hold a pint and a half of water.

The wild animals of Palawan are not very numerous; there are several varieties of the monkeys, also the pakdá or big ape, and porcupines; the birds are mostly of unusual species. Reptiles are abundant; alligators are commonly found in the lakes and swamps, and the pythons are unusually large, specimens over 22 feet long having been found.

Industrial Resources.—The resources of the island are as yet poorly developed. The chief industry is the raising of cattle, hogs and goats; goats and fowls are bartered with the ships along the coast. Rice, tobacco, nutmegs,

sweet potatoes and other food products are raised for home consumption, and there are a few primitive manufactures also for domestic use. Edible birds' nests are found in large numbers in the rocky caverns of the coasts; they are of excellent quality, being considered second only to those of Peñon de Coron (q.v.), and have brought twice their weight in silver in the Chinese market. Honey and wax are also collected and brought to the coast for trade. There are no roads, except a few portages, but a number of trails; the rivers also afford means of transportation near the coast. Only the coast is suitable for agriculture.

People and History.—Next to the Visayans, the dominating race of the northern and central parts of the island are the Tagbanuas (q.v.), a peaceful and docile race of mixed Malay and Negrito blood. The Moros predominate in the southern part, south of the 10th parallel of latitude. Previous to the 18th century Palawan was a part of the sultanate of Borneo; in the early part of that century, the Spaniards established several garrisons in the northern part of the island for the purpose of protecting their dominions on the north from the Moro pirates, and the island was soon afterward ceded to Spain. In 1885 a special attempt was made by the Spanish government to colonize Palawan by offering settlers free transportation and other privileges, but this failed. An attempt to establish a convict settlement was also unsuccessful, and Spanish authority was recognized only along the coast. The United States troops occupied Palawan in the early part of 1902, and in June of that year civil government was established in that part of the island lying north of the 10th parallel of latitude. This region with its dependent islands is known as the province of Paragua. Its capital is on the island of Cuyo. The part south of this parallel, known as the country of the Moros, is as yet without civil government. The most important town of Moro Palawan is Puerto Princesa, which has not 2,000 inhabitants. The island of Balabac, lying south of Palawan, is governed in accordance with the terms of the treaty with the Sultan of Sulu. At Iwahig near Puerto Princesa there is a modern penal colony on liberal lines. On the small island of Culian there is a leper colony. Population of the island about 35,000.

PALAWAN PASSAGE, the route through the Balabac Strait and along the east coast of Palawan, used by vessels in the trade between China and Manila during the latter part of the southwest monsoons, because more sheltered than the China Sea route to the west of Palawan. This route was first explored in 1850 by Captain Bates of the British navy, and soon afterward generally adopted.

PALAY, a tropical African climbing plant (*Cryptostegia grandiflora*) of the milkweed family. Its stalk-fibres, which are strong and white, are spun into a very fine yarn; and its milky juice forms a kind of caoutchouc. It is used for this latter purpose in Burma.

PALAZZO PITTI, pā-lăt'sō pīt'tē, a palace in Florence. See FLORENCE.

PALE, in heraldry, a figure of the group known as ordinaries, consisting of a broad perpendicular band in the middle of the shield.

Several charges of any kind are said to be "in pale" when they stand over each other perpendicularly, as do the three lions of England. A shield divided through the middle by a perpendicular line is said to be "parted per pale." When divided into an even number of parts by perpendicular lines, it is "paly of" so many pieces.

PALE, The English, Ireland, a name applied in the 14th century to that part of Ireland which was completely under English rule, to distinguish it from the parts where the old Irish laws and customs prevailed. It varied in extent at different periods, consisting of Dublin and more or less of the neighboring country.

PALE OF SETTLEMENT, that part of Russia within which Jews are allowed to reside. The Pale was established in 1791 to prevent the Jews of White Russia, who came under Russian dominion in 1772, at the first partition of Poland, from spreading throughout Russia. Its boundaries have varied from time to time; in 1904 it contained the governments of Bessarabia, Vilna, Vitebsk, Volhynia, Grodino, Yokaterinoslav, Kovno, Minsk, Moghilef, Podolia, Poltava, Taurida, Kherson, Chernigov and Kiev. Within these governments the Jews were not in general permitted to settle outside the cities and towns. They were allowed to live in Poland also, but this was not considered as part of the pale. Under certain narrow restrictions, they were also permitted to live in Courland, the Caucasus and Turkestan. They were entirely excluded from Finland, and except in the case of convicts and their children, from Siberia. In Moscow, too, they were subject to particularly narrow restrictions. In 1903 the restrictions on the Jews were somewhat mollified. In 1904 the pale of settlement might be left by merchants of the first guild and their families, persons possessed of a higher education, those who had completed the military service before 1874 and skilled artisans. The same classes were permitted to reside in villages. Unrestricted rights of residence were accorded to veterans of the Japanese War, manufacturers and counsellors of commerce. Restriction to the pale has been abolished by the Russian revolutionaries in 1917 along with all other religious and racial disabilities.

PALEA, plural **PALEÆ**, the bracts, usually membranous and colorless, on the receptacle of a composite plant between the florets; the chaff. Also the bracts-immediately surrounding the fertile leaves organs in grasses. See BRACT; FLOWER.

PALEARIO, pā-lā-ä'rē-rō, Antonio, more correctly, ANTONIO DEI PAGLIARICI, and according to his Latinized title AONIUS PALEARIUS, Italian religious innovator: b. Veroli, Roman Campagna, 1500; d. Rome, 1570. He was a teacher of rhetoric at Perosa, Siena, Padua, Lucca and Milan, whose reputation had spread over all Italy and abroad. He made his home especially at Siena, and in 1567 was brought before the Holy Inquisition at Rome, and three years later suffered martyrdom at the stake. His principal work is a long Latin didactic poem, 'De Immortalitate Animarum.' Famous as his poetic and theological writings were,

equally popular was the work attributed to him, 'Del Beneficio de Giesú Christo Crocifixso' (1548), which was translated into several languages, but in 1549 was suppressed by the Inquisition. It was published at Cambridge, England (1853), and at Leipzig with a German translation by Tischendorf (1856). Ranke maintained it to be the work of a Benedictine monk, Benedetto of Mantua. Consult Young, 'Life and Times of Antonio Palerío' (London 1860); Bonnet, 'Aonio Palerio' (Paris 1863).

PALEMBANG, pä-lēm-bäng', Sumatra, Dutch residency in the southeastern part of the island; also the capital city of the residency. The country is drained by the Musi (or Moesi) River, along the banks of which there are valuable supplies of petroleum. An alluvial plain and plentifully watered, it is very fertile. Its native inhabitants are Moslem Malays, except a race called Orang-Kubu, living by the chase in the thickest jungles and exhibiting a very primitive culture. Palembang residency has an area of 53,497 square miles and a population of about 700,000, of whom 373 are Europeans, 1,876 Arabs and 6,451 Chinese.

Its capital city of the same name lies on both banks of the Musi, 80 miles from its mouth, in a swampy region, the houses being sometimes built in the very stream. The old Javanese name for the city seems to have been Malayo, so that it may be the Malajour of Marco Polo and the Mo-lou-yu of the Chinese geographers. An attempt has been made to prove that the town was once held by Hindus, an occupation like that in Java. The main building is an 18th century mosque. Coffee and pepper are exported; and there is some trade in silks, carvings and goldsmiths' wares. The Dutch built a factory here in 1618, but the country remained independent until 1812 when it was occupied by the English. It passed to the Dutch after 1825. Pop. over 60,000.

PALENQUE, Mexico, the most individual and distinctively interesting of the ruined cities belonging to the pre-Columbian civilization of America.

Palenque lies in the foot-hills, on both sides of the mountain stream Otolum, or Otula (the Place of Falling Stones). It is some six miles from Santo Domingo del Palenque, Chiapas. Owing to the dense tropical vegetation which abounds in this district the ruins have been but very imperfectly explored. But enough has been ascertained concerning them to fix their character undoubtedly as a very important pre-Columbian religious centre. The absence of fortifications of any kind and the open character of the buildings together with their peculiar structure would seem to indicate this; and the mythological scenes depicted in the stucco work within several of the edifices confirm this opinion.

Owing to its peculiar character, its one-time undoubted importance, its proximity to other places visited by the Spaniards shortly after the Conquest and the fact that it is mentioned in none of the accounts or reports of this period, would seem to indicate that Palenque was a deserted city previous to the discovery of Yucatan and Mexico. Up to the time the ruins were discovered in 1746 and officially brought to the attention of the Spanish government, apparently their existence had not been known

except to the aboriginal inhabitants of the surrounding district. But commencing shortly thereafter and continuing down to the present time, numerous partial examinations and explorations of the ruins, official and private, have been made; yet not enough of a sufficiently-extended character has been done to definitely settle the relationship of Palenque to the other civilizations by which it was surrounded, either at the time of its foundation or subsequent growth to power and influence.

Many of the original buildings of Palenque must have disappeared; in fact, Calderón, one of the first to describe the city says that he counted 206 buildings, most of them more or less in ruins. Of these the most distinctive and important is the edifice known as the "Palace." This stands upon a pyramid some 60 feet high, which rises from a narrow plain on the left bank of the river. Up the eastern side of the pyramid, which is 263 by 310 feet square, runs a broad stairway centrally placed. There was probably a similar one on the north. The sides of the pyramid were originally faced with blocks of cut stone, but these are now displaced and many of them thrown down by the excessive growth of tropical vegetation. This was the more easily effected since the mass of the pyramid is composed of earth and loose stones. The "Palace" crowning the pyramid is 240 feet long and 180 wide. It is surrounded by a narrow passageway formed by the summit of the pyramid. The Palace has over 40 doors, 9 feet wide and $8\frac{1}{2}$ high, facing outward on to this passageway. These lead, on the north and east, into one long corridor-like apartment running along both these sides and 60 feet around the south end and 40 feet around the west side, a total distance of over 500 feet, without an intervening wall or obstruction of any kind. On the west, the whole length of the corridor contains only two divisions, while on the south there are five, two of which are pierced by connecting doors. Within this great corridor runs a second corridor of like width facing on an immense patio or courtyard. Half of this corridor is taken up with one long room running round the north and east sides. Many doors open from this latter corridor into the courtyard, which is divided into four nearly equal parts or smaller courts. In these courts are subsidiary buildings, one of which contains seven rooms, one quite large. From the patio rises a great tower 30 feet square at the base, and standing 60 feet above the level of the court, in five sections consisting of the base proper and four stories. It is probable that the 100 or more doors of the palace were covered with curtains which would have been sufficient protection in a tropical climate. In the rooms of the building, on the stairways and outer walls is a luxuriant display of excellent stucco and bas-reliefs showing well-executed human figures and stucco tablets. The edifice is plastered throughout. Numerous stone stairways connect the corridors and the rooms with the courts. Underneath the "Palace" and within the pyramid are numerous rooms, all of which so far as explored are plastered. They are apparently the same in form as the upper rooms and connected with them by stairways. They are said to have once contained decorated tablets; but if so the dampness has destroyed them. A similar building in form and position

to the "Palace" is the "Temple of the Three Tablets." The incline side of the pyramid from which it rises is 110 feet on the sloping side. The Temple itself is 76 feet long, 25 feet wide and 35 high. In the façade are five wide doors; on the walls between are well-executed bas-reliefs in stucco and on the corner front walls are columns of hieroglyphics. One long room takes up the front of the building and from this three doors lead each into a back room. Here are two large stone tablets and nearly 400 sculptured hieroglyphics, which are supposed to have been used either for educational purposes or for the administration of the law. "The Temple of the Beau Relief" contains a life-sized figure sitting on a throne terminating on the right and the left in finely executed tiger's heads. The whole, which is in stucco, is one of the best pieces of native modeling found in America. The building is also situated on a pyramid and is 20 feet square by 25 feet high. Another noted building in Palenque is the Temple of the Cross, not so much on account of the edifice itself as through the famous "Palenque Cross" that once stood within its shrine. It stands upon a stone-faced pyramid which measures 134 feet up the sloping side. The Temple is 50 feet long, 31 feet wide and 40 high. It has three wide doors in the façade, and between them tablets in stucco and other skilful decorations. The space between the outer doors and the corners are covered with hieroglyphics; and the sloping roof with artistic stucco decorations. On the roof is a two-story structure 35 by 30 feet and 16 feet high, also decorated in elaborate stucco. The Temple consists of an outer room from which doors lead into three rooms at the back. In the centre or larger of these rooms on the rear wall was the tablet of the cross, or rather the three tablets of the cross, which are now in the National Museum in Mexico City. (See CROSS OF PALENQUE). The Temple of the Sun, which stands on a twin pyramid almost as high as that of the Temple of the Cross, is similar to the latter in form and plan. It is still more remarkable than the other buildings for its variety of fine stucco work and ornamentation. It has the same disposition of stucco work and hieroglyphics on the façade, which is 38 feet long, the depth of the building being 28 feet. On the rear wall of the inner sanctuary is the tablet of the Sun consisting of three slabs, the centre of which contained the main subject, the offering to the sun, and the other two, like those of the cross, are covered with explanatory hieroglyphics. The space covered by the tablets is 8 by 9 feet. Near here is an aqueduct of stone 217 feet long. But it was at one time evidently longer. North of the palace are the foundations, mounds and other remains of 11 buildings; and on a hill to the east is another foundation and around it other ruins. At least two ancient bridges exist north of the Palace, one of which is 56 feet long by 42 wide and built of large hewn blocks of stone; while another lies some distance west. Some way south, in the tropical forest, are two other pyramids of considerable height, while in every direction are still the evidences of a once populous centre. Consult Bancroft, H. H., 'The Native Races of the Pacific States' (5 vols., San Francisco 1883); Bandelier, A. F. A., 'Report on an Archæological Tour, in Mexico

PALEOBOTANY. The science of the extinct plants and plant assemblages of the globe. That branch of paleontological science dealing with the endless succession of plants which have inhabited the earth since life first came into existence. Its story is the history of vegetations and their interactions with complex and ever-changing environments through eons of time that resulted in populating the earth's surface with a succession of floras and finally in the production of the relatively modern and highly specialized races of flowering plants. Its aim is not the mere assembling of facts, but the understanding and interpretation of these facts in their relation to the evolution of individuals and communities and earth history.

History.—Despite the great abundance of fossil plants in the countries of the classical world surrounding the Mediterranean, the limestone quarries of the Greeks, the petrified forests of Nubia and the vast public works of Imperial Rome, none of the writers of antiquity mention fossil plants, although some of them carried on a lively discussion regarding the nature of animal fossils. Petrified wood is not recorded until about the middle of the 13th century (Albertus Magnus) and fossil foliage not before the latter half of the 17th century (Major Lhwyd). The earlier commentators explained fossils as due to the mystical action of the stars or the mysterious working of spiritual forces like the *vis lapidifica* of Avicenna or the *virtus formativa* of Albertus Magnus or the stone-making spirit of Sperling. Nothing was farther from the accepted thought than that fossils were the remains of real organisms that once lived, the nearest approach to such a view being that they were some of the models used by the creator, or that they had developed from abortive germs of animals and plants that had become lost in the earth. After the view that fossils were the remains of organisms had gained many adherents they were regarded as evidence of the universal deluge—an interpretation suggested by Martin Luther in 1539. This flood theory or diluvial hypothesis found numerous advocates throughout the 17th and even far into the 18th century. For example, in the 'Transactions' of the Royal Society for 1757 James Parsons figures numerous fossil fruits from the early Eocene deposits of Sheppey in the Thames estuary. These he thought would furnish evidence of the season of the year in which Noah and the rest of creation were obliged to take refuge in the ark, and he concludes from the maturity of these fossil fruits that the deluge commenced in the fall of the year and not in the spring as his contemporary Dr. Woodward had supposed. Johann Jacob Scheuchzer (1672-1733) was the

great exponent of the flood theory, publishing his *Herbarium Diluvianum* at Zürich in 1709, and even figuring the bones of one of Noah's less fortunate brethren which he found among the fossil leaves at Oeningen and which subsequently proved to be the bones of a large Miocene amphibian. The flood theory passed through various phases of opinion. At first the fossil plants were regarded as similar to those still growing in the vicinity—a natural enough belief when the universal acceptance of the Mosaic cosmology and a world but 6,000 years old is borne in mind. Subsequently when the differences in the fossils became apparent they were thought to represent forms still existing in the tropics that had been swept to Europe and buried by the waters of the flood. When with the progress of knowledge of tropical plants this last view became untenable it was thought that the fossils represented plants that had been exterminated by the flood, and from this it was but a slight step to the opinion advocated by Volkmann, which appealed to many, that the antediluvian vegetation was of a far higher order than that of the present, with none of the thistles or other weeds of modern times, and that our modern forest trees are the degenerate descendants of delightful Adamitic fruit trees—a phylogenetical fall paralleling and ascribed to the fall of man. Gradually it came to be recognized that fossil plants were not only unlike recent ones, but that they were very ancient and not merely antediluvian, but pre-Adamitic, a view first advocated by Blumenbach (1790). The first year of the 19th century saw the publication of the 'Beiträge zur Flora der Vorwelt' by Ernst Friedrich von Schlotheim (1764-1832) in which 14 plates of fossil plants were published and these plants were segregated into 5 classes and 12 orders based upon the method of preservation. The next work of importance with a somewhat different point of view, as its title indicates, was the 'Versuch einer geognostisch-botanischen Darstellung der Flora der Vorwelt,' published in parts from 1820-38 by Kaspar Maria von Sternberg (1761-1838). The vegetation of the world was divided into three periods—an older insular period characterized by the coal plants; a period marked by cycadean types, which corresponds roughly with the modern Mesozoic, and a period introduced by fucoidal remains and characterized by dicotyledonous leaves, which corresponds with the modern Cenozoic. The real nestor of paleobotany, however, was Adolphe Theodore Brongniart (1801-76), son of Alexandre who was associated with Cuvier in his great work on the Paris Basin. Brongniart commenced publishing on fossil plants at the early age of 21 and in 1828 in his *Prodrome* to the 'Histoire des végétaux fossiles' he drops the prevailing point of view and treats fossil plants as none the less plants, endeavoring to fit them into the natural system of classification of Jussieu, and recognizing the true position of the gymnosperms a generation or more before the students of the modern conifers arrived at the same point of view. Brongniart maintained that there had been a steady progress from lower to higher forms. He believed in a gradually ameliorating climate, and divided the vegetation into four periods, the first extending from the beginning to the end of the Carboniferous, the second corresponding to the

early Triassic (grès bigarre), the third including the later Triassic, the Jurassic and Cretaceous, and the fourth making up the Tertiary and Quaternary or Cenozoic. He thus laid the foundations of the science in a broad way and was the inspiration of numerous students who grew to productivity under his tutelage and example. During the remainder of the 19th century a vast body of literature was built up by an ever-increasing number of students of whom the most illustrious were H. R. Goeppert (1800-84) of Silesia, Franz Unger (1800-70) of Styria, Oswald Heer (1809-83) of Switzerland, Gaston de Saporta (1823-95) of France and C. von Ettingshausen (1826-97) of Austria. In Britain W. C. Williamson (1816-95), following the pioneer work of Witham (1833) and Binney (1868), succeeded in placing the anatomical study of petrified plants of the Carboniferous on a solid foundation, and this phase of activity is still assiduously cultivated by a considerable number of contemporary British botanists, among whom D. H. Scott unquestionably stands at the head. In France the most active contributors in recent years have been Bernard Renault (1836-1904) to the anatomical side and C. Rene Zeiller (1847-1916) to all phases of the subject. Probably the most capable of contemporary paleobotanists is A. G. Nathorst of Stockholm.

The pioneer workers in North America were J. W. Dawson (1820-99) in Canada, and Leo Lesquereux (1806-89) and J. S. Newberry (1822-92) in the United States. Unger in his 'Genera et Species Plantarum Fossilium' had essayed a complete manual of the subject as early as 1850, but a sufficiently large body of facts had not yet been accumulated to give his work lasting value, although it was of immense importance at that time. This task was accomplished by W. P. Schimper (1808-80) in three volumes of text and one of plates of the 'Traité de paléontologie végétale' (1869-74). A less usable work covering the same field in a different way was the 'Paleophytologie' contributed by Schimper and Schenk to Zittel's 'Handbuch der Paläontologie' which was completed in 1890. More recently A. C. Seward has essayed to cover the field in a four-volume work on fossil plants (1898-1918) in which little space is devoted to other than the morphological aspects of the subject and in which the flowering plants are entirely omitted. Other of the more important treatises on paleobotany are listed in the bibliography at the end of the article.

Methods of Preservation.—Fossil plants have been preserved by two principal methods. They either became water-logged and buried in sediment ranging from mud to sand, or were infiltrated by some mineral solution or were replaced molecularly by silicic acid, calcium carbonate or other mineral substance. The first method is called inclusion and the degree with which the details are preserved in the resulting impression depends on the fineness of grain of the sediment. Very fine muds preserve every detail with great fidelity. Therefore shales, which are simply lithified muds, furnish beautiful fossils, as in the roofing shales that overlie so many coal seams. The redeposition of calcium carbonate in the form of travertine often entombs well-preserved plant remains as do the alluvial muds of river

flood plains. Volcanic dust falling in water forms an admirable matrix. Impressions of plants constitute the bulk of the objects with which the paleobotanist has to deal. The substance of the enclosed plant fragment may remain as a carbonaceous film, it may be replaced by salts of iron or other mineral or it may be entirely dissipated, leaving merely the impres-

Plant remains are often found in a good state of preservation in nodules of iron or calcium carbonate. Coal or lignite beds are simply examples of the inclusion of vegetable *débris en masse*. In coarse sediments, or occasionally in finer materials such as tuffs or travertine, more resistant objects like seeds or stem fragments have left nothing but the cavity or cast,

and such objects often furnish satisfactory subjects for study. Amber or other fossil resin has also frequently preserved mummies of plants or other organic remains, especially delicate objects like flowers. The cuticularized integument of pollen grains or spores is very resistant and is frequently preserved. Similarly the cuticles of leaves retaining the outlines of the epidermal cells and the stomata are often found to be intact after the remaining tissues have become completely disorganized. These can sometimes be peeled from the fossils and mounted for microscopical examination or if this is impossible colloidal casts of the surface can be made and by the proper handling of the illumination yield satisfactory microscopic details. The second and third methods of preservation, or more generally a combination of infiltration and replacement, are usually termed petrification. The internal structure of the plant material is conserved with more or less perfection according to the rapidity of permeation before the tissues rotted and the completeness with which replacement took place. If this happened before the tissues became disorganized thin sections may be ground and the histology elucidated. Petrified woods, especially of coniferous trees, either silicified, calcified or ferruginized, are common at many geological horizons. More delicate plant fragments are only rarely preserved in this way. Such remains, where the replacement has been by calcium carbonate, characterize certain horizons of the English Coal Measures, and similar "coal balls" have been discovered more recently in Moravia, Westphalia and Russia. Silici-

FIG. 1.—Diagram Showing the Geological History and Increasing Complexity of the Vegetable Kingdom.

sion. Occasionally lignified remains such as those from certain localities in the Upper Cretaceous may retain their internal structure more or less intact and by special methods may be sectioned and studied microscopically. The fire-clays of the coal measures often furnish beautiful impressions in dark tints on a light drab background, and some of the light-colored clays of the Upper Cretaceous of South Carolina, where the leaf substance has been replaced by iron oxide, yield handsome red impressions.

fied plant fossils are found at certain horizons in the Permian of Saint Étienne and Autun in France and often the most delicate thin-walled tissue such as cambium and phloem is well preserved. The stumps of Cycadeoidea from the American Lower Cretaceous are silicified, usually denoting a burial in sandy deposits, and range in perfection from those of the Lower Cretaceous of Maryland which are little more than sandstone casts to some of the wonderfully preserved stumps of the Black Hills

and Wyoming in which even the embryos in the ovules are completely preserved.

General Principles.—The general principles which paleobotany has elucidated or illustrated can be but briefly indicated. First among these is the fact, roughly traced in the subsequent discussion, that the history of plants shows a gradual transformation from early simplicity to later complexity and a progressive differentiation of both structures and habits in the successively higher groups, thus exemplifying the universal principle of evolution. The original scene of plant activity was in the water. Gradually the main theatre of operations was transferred to the land and the distinction between vascular and cellular plants in this respect is analogous to the distinction between vertebrate and invertebrate animals. Each successive group of plants that appeared upon the scene illustrates a second great principle—that of adaptive radiation. That is, by progressive modifications (the mutations of Waagen) groups became dominant, as, for example, the *Lepidophytes*, *Arthropytes* and *Pteridosperms* of the Carboniferous or the *Cycadophytes* of the Mesozoic or the *Angiosperms* of the Cenozoic; their members became adapted for a great variety of environments and tended to occupy all of the available situations on the land or in some cases became secondarily adapted for an aquatic existence, like the water ferns or the various aquatic angiosperms. Paleobotany shows one group after another thus dominating, becoming specialized during the process and then waning or becoming entirely extinct. The accompanying diagram illustrates the successive dominance of different plant types and the increasing complexity of the vegetable kingdom as a whole. (Fig. 1). Another principle is illustrated by the progressive loss of plasticity as organisms or organs became complex and specialized. It was the simpler organisms that outlasted the complex or gave origin to new types. The more complex lost their power of adaptability to change and readily succumbed when such changes in their environment came. For example, it was not the complex arborescent lepidodendroids that gave rise to the modern club mosses, nor were the lofty calamites the progenitors of the modern mares tails, but in each case simpler forms saved the phylum from extinction. Fern synangia may have given rise to seeds by modification and peripheral sterilization, but no seed has or ever will become modified into a synangium. Thus evolution either of organs or organisms is non-reversible. The earlier forms of the successive plant groups, in accordance with the a priori conclusions of evolutionary philosophy, are in general synthetic or generalized in structure, i.e., they combine features of various categories that subsequently became characteristic of diverging lines of evolution. Thus all of the earlier plants had motile sperms, none had true vessels such as characterize the wood of angiosperms, cryptogamic or centripetal wood formation was an almost universal feature, and many other similar characters could be mentioned. The *Sphenophyllales* were synthetic in that they combined certain characters of their fern ancestry with features that subsequently became stereotyped in the *Lepidophytes* and *Calamites*—they are thus considered as representing an

approach to the common ancestor of the balance of the *Lepidophytes* and of the *Arthropytes*. The earliest ferns show combinations of features that subsequently became the property of different fern families; while the *Pteridosperms* combined the characters of ferns and *cycadophytes*. Another principle illustrated by paleobotany is that known as recapitulation, or the fact that, theoretically at least, the ontogeny or development of the individual is an epitome or abridgment of the phylogeny or development of the race. This principle is, however, difficult of application since its underlying factors are unknown and the ontogeny may show acceleration, modification or obsolescence that renders the bearing of recapitulation questionable unless corroborated by other lines of evidence. A familiar instance of the retention by the seedling of ancestral adult characters is furnished by the conifers, most of which have needle leaves on the shoots of the juvenile forms while with age these needle leaves of the long shoots are replaced by scales as in an adult pine or become reduced to concrescent leaves with a cyclic instead of a spiral arrangement as in the juniper, or become reduced to scales while the shoot (phylloclad) functions as a leaf as in *Phyllocladus*. From these changes in foliage in the earlier part of the life history of the various conifers it is inferred that the scale leaves of *Pinus*, the double leaf of *Sciadopitys*, the phylloclad of *Phyllocladus*, the concrescent cyclic leaves of the *Cupressaceæ* and the deciduous habit of the larch (*Larix*) and bald cypress (*Taxodium*) are all derived characters. Another principle is derived from the study of persistence of organisms or organs. Such conservative organisms as the *Bacteria* or the *Cyanophyceæ* have existed unchanged for millions of years. Conservative organs are those like roots, whose functions and environment have remained uniform for ages. Thus all roots are found to be much alike in their organization. Various enthusiasts have proclaimed the conservatism of the vascular cylinder, while others conceive that the parts concerned with spore or seed formation are more conservative. Foliage in general is apt to be conservative in both form and structure, as witness the similarities in the fronds of the *Cycadophytes* retained from the Permian to the present during which their stem structure and especially their fructifications varied through wide limits. *Ginkgo* leaves have an equally long history and many existing angiosperms acquired their distinguishing leaf form during the Upper Cretaceous. Another general principle derived from the study of the geological distribution of plants—a principle for the most part unrealized by biologists or meteorologists—is that relating to geological climates, of which plants are the most satisfactory known tests. The early paleobotanists drew extreme pictures of former vapor-laden atmospheres and tepid torrid climates, but these are found to have no basis. On the other hand it has become increasingly clear of late years that the sort of climate under which the history of man has been passed is an abnormal climate from the standpoint of geological history. From the first appearance of terrestrial plants in the Devonian down to the present there are only two periods at which it is pos-

sible to distinguish anything approaching climatic zoning. For example, Devonian plants are known from Ellesmere Land on the north to Australia on the south and no differences are discernible in the floras from lat. 85° and those contemporaneous in central Europe. This uniformity and cosmopolitan distribution continues throughout the Lower and Upper Carboniferous. In the Permian, however, there are well-marked floral provinces succeeding widespread glacial conditions. Again from the late Triassic throughout the Jurassic and Cretaceous there were no polar, temperate or equatorial zones—the same plants are found within a few degrees of the poles as within a few degrees of the equator. Even in the earlier Tertiary tropical floras extended half way across the temperate zones and temperate forests are known from within five degrees of the pole. At the close of the Tertiary the successive glaciations of the Pleistocene changed all this cosmopolitanism and to-day man is living in a Pleistocene climate, with well-marked climatic zones and seasonal variations. The principle may be stated thus: That for geological time, as a whole, climates have been more uniform than at present and marked variations from this uniformity are occasional and are the concomitants of glacial conditions, both apparently the results of a similar but little understood cause.

Relation to Other Sciences.—Paleobotany both contributes to and borrows from the other earth sciences. Its relation to botany in the accepted sense of that term is peculiar since Paleobotany is the botany of all geological time while botany is that of but one geological period, namely—the present. It is now quite impossible to obtain a broad foundation for phylogenetic, morphological or distributional studies of existing plants without a consideration of their extinct ancestors. In the interpretation of the far distant past paleobotany and its sister science paleozoology contribute fundamental data to geology, not only in furnishing the “medals of creation,” which constitute the best basis for a geological chronology yet discovered; not only as comprising the subject matter of the biology of the past, which is a legitimate part of earth history; but in the elucidation of the climate and other physical conditions of past times, subjects which may be embraced under the terms of Paleoclimatology and Paleogeography. Paleogeography, or the Physical Geography of past times, also derives some of its most important facts from the study of the character and distribution of fossil organisms.

Thallophyta.—As a convenience and because of their lack of importance as fossils the old term Thallophyta will be used for the great mass of thallus plants, formerly thought to constitute a single sub-kingdom but now known to represent several phylæ. The thallophytes embrace plants of the simplest type, but they exhibit nevertheless a very wide range in the structure and degree of differentiation of the vegetative body and in their methods of reproduction. The plant body may be a single minute and often motile cell multiplying by fission, or the thallus may be an aggregate of cells with a well-marked physiological division of labor, and differentiated into parts analogous

to the roots, stems and leaves of the higher plants, and with a corresponding histological complexity. The thallus best-known plants to the non-botanist are bacteria, such fungi as molds and toadstools and seaweeds. With but few exceptions marine plants are thallophytes, although immense numbers are also found in fresh water and in various terrestrial habitats. In general the larger and more complex are marine and some of these are among the most gigantic of plants. The thallophytes are primitive types and their existence unquestionably antedates the geological record, although they are now known in considerable variety from the pre-Cambrian. They furnish little that is of paleobotanical interest since they are either so slightly resistant that they have left only illy defined impressions in the rocks, or, if they had hard parts as in the so-called calcareous algæ, these, while they are often abundant, as in the various limestones of Paleozoic, Mesozoic and Cenozoic age, add little to the knowledge obtained from a study of existing forms. They are, however, of great philosophic interest since they point to the steps in the evolutions of the first life forms and since also they are unquestionably the ancestors of the land plants which appear in the Devonian deposits and from which all of our existing terrestrial vegetation has been evolved. A few of the more important fossil types will be briefly enumerated. Proterozoic algæ are represented by the large concentrically laminated calcareous deposits known as Cryptozoon, as well as by other forms referred by Walcott to the genera *Weedia*, *Collenia*, *Newlandia*, *Kinneyia*, *Greysonia*, etc. Thousands of obscure tracings in the Paleozoic and later rocks have been described as fossil seaweeds but large numbers of these supposed furoids have been shown to be the casts of trails, burrows and similar tracks of worms, trilobites and other marine organisms while others are rill or current markings of non-organic origin. Nevertheless there is no reason for doubting the presence of algæ from the pre-Cambrian onward, particularly when the supposed fossils show a carbonaceous residue as in the genus *Spirophyton* of the middle Devonian. The genus *Nematophycus* of the Silurian and Devonian includes gigantic forms with their internal structure preserved, the silicified stems of *N. logani* being sometimes several feet in diameter. The Diatomaceæ (*Bacillariaceæ*), whose siliceous frustules accumulate as ooze in the present marine and fresh waters, occur as fossils from the lower Jurassic onward. They are sometimes present in the Tertiary as relatively pure beds many feet in thickness and made up of billions of tests of these tiny forms, as in the Miocene Calvert formation of Maryland and Virginia, or in the Pliocene of California. The Chlorophyceæ or green algæ include many doubtful fossil forms and numerous others that are well authenticated, particularly in the somewhat unique group of *Siphonææ*. Joints of the verticillate or tubular calcareous forms occur in the older Paleozoic (Cambrian to Silurian) where they are represented by the genera *Ascosoma*, *Primicorallina*, *Sycidium*, *Callithamnopsis*, etc. This type becomes exceedingly common at certain Mesozoic and Cenozoic horizons, as in the Mediterranean Trias-

they have been recorded from the Paleozoic, especially by the early students, these forms usually resolve themselves into fragments of Lepidophyte, Arthrophyte or Coniferophyte foliage. None are conclusively known earlier than the Mesozoic and the liverworts antedate the true mosses in the record, furnishing therefore conclusive evidence of the latter group being unknown in rocks older than the Tertiary.

Pteridophyta.—The Pteridophyta as here understood is restricted to the fern phylum—the Filicales—the so-called fern allies (club mosses and horsetails) being grouped in the phylæ Arthrophyta and Lepidophyta. The Pteridophyta are a very ancient stock, always megaphyllous and phyllosiphonic. The fructifications are borne upon but slightly modified foliage leaves and were never strobiloid. The known forms are prevailingly homosporous, although heterospory must have been evolved early in their history since the Pteridosperms are clearly derived from the early, at least pre-Devonian fern stock. Among existing ferns the Rydropterales, or so-called water ferns, of somewhat questionable relationships, are also heterosporous.

Living ferns are usually segregated into two major groups—the Eusporangiate and Leptosporangiate according as the sporangium develops from a group or from only a single cell. While this distinction is not without exception, it is one not observable in fossils, where the mature features must be relied upon. On the whole the Eusporangiate sporangia are large, attached by a broad base, with a wall more than one cell thick, and without a definite annulus, though some of the cells may be thickened; moreover in the Marrattiales, one of the important orders from the paleobotanical viewpoint, the sporangia are united to form synangia, which by some students are thought to be a modification of the sporangiophore so prominent in the Arthrophyta, and vestigial in the Lepidophyta. In the present treatment the Pteridophyta are segregated into the four classes—Cœnopteridæ, Eusporangiatæ, Leptosporangiatæ and Hydropteridæ—which will be considered separately.

The Cœnopteridæ or Prinofilices comprise a group of Paleozoic ferns known almost entirely from the anatomy of stems and petioles, the features of which are probably overestimated in discussing their inter-relationships. The group is considered to have been much wider than is indicated by our knowledge of the two families Botryopteraceæ and Zygopteraceæ, and in the accompanying phylogenetic diagram is used as the starting point of the fern phylum.

Without attempting to formulate the theoretic charters of the Eofilices or setting diagnostic bounds to the Cœnopteridæ as here used we may pass to a brief consideration of the two known families.

The Botryopteraceæ at present embraces three genera—Grammatopteris and Tubicaulis based upon Permian stem anatomy and Botryopteris based upon stem and sporangial structural remains ranging in age from the Lower Carboniferous to the Permian. Little is known of the habits or fronds of these types and they have not been definitely correlated with ma-

terial preserved as impressions. They had slender monostelic stems exarch in Grammatopteris and Tubicaulis, endarch in Botryopteris, with scalariform or reticulate tracheids. In *B. forensis* the sporangia were pedicellate in groups of from two to six on the ultimate divisions of compound fronds. They were pyriform with walls of two layers of cells and on one side had an annulus several cells in width suggesting comparison with the Osmundales. The leaf-traces vary from rectangular in Brammatopteris and oval in some species of Botryopteris to omega shaped in other species of that genus.

All known Botryopteraceæ were small plants thought to have had slightly fleshy pinnules, and abundantly clothed with epidermal hairs.

The family Zygopteraceæ is based largely on a variety of structural remains of petioles, although the stem anatomy and sporangial structure are known in several instances. They range in age from the Devonian (Clepsydropsis) to the Permian. The leaf traces show a variety of complexities of form and histology and in cross section range from an hour glass or H shape to the stellate form of *Asterochlæna*.

The sporangial characters show considerable variation. In Zygopteris the sporangia were grouped and annulate much as in Botryopteris. In *Diplolabis* and *Stauropteris* an annulus was not developed; the former had the sporangia grouped in sori or synangia while in the latter they were borne singly on the ultimate divisions of the frond. The class as a whole shows relationships with the Ophioglossales, Osmundales and Marattiales.

The Eusporangiate class of ferns comprise two known orders, the Ophioglossales and Marattiales, the former regarded as very primitive by most students and but slightly represented in the fossil state, although the Paleozoic Rhacopteris and Ophioglossites and the Mesozoic Chiropteris have often been considered as representing this order.

The Marattiales, on the other hand, had an extended geological history. In the present state of our knowledge, confused as it is by the resemblance of Pteridosperm microsporangia to Maratteaceus synangia, it is difficult to give a satisfactory estimate of the relative importance of the Marattiales in the Paleozoic, but they certainly occupied a prominent position, and this prominence, rests on the evidence of the cosmopolitan frond genus *Pecopteris*, the stem anatomy of the forms referred to *Psaronius* and its allies, and upon a variety of fructifications. The *Psaroniaceæ* were tree ferns sometimes 50 feet or more tall, with fronds in cases where actual connection has been established of the *Pecopteris* type, and arranged in crowded spirals (*Psaronius polystich-Caulopteris* impressions), in four vertical rows (*Psaronius tetrastichi*) or in two opposite vertical rows (*Psaronius distichi-Megaphyton* impressions). A very large number of species have been described from the Upper Carboniferous and Permian. They have been favorite objects of histological investigation since they are common in a petrified condition in Saxony, France and elsewhere. Anatomically the stems have a complex system of laterally elongated, concentric curved steles of scalariform tracheids surrounded by phloem and immersed in a paren-

chymatous ground mass with some sclerotic bands below the leaf gaps. Some of the polyarch roots show secondary wood but none has been observed in the stems, the central one cauline and the outer ones giving off numerous leaf-traces and adventitious roots. Outside the sclerenchymatous zone which bounds the stem proper is a very broad zone, formerly thought to be cortical, consisting of closely packed adventitious roots embedded in a dense felt of hairs which spring from both the stem and the roots. The petioles usually show a single horse-shoe-shaped trace although sometimes a second lies within the first. The occasional presence of lacunae in the root cortex of some of the species suggests a swampy sub-stratum.

Pecopteris fronds represent the one type among the many familiar fern-like fronds of the Paleozoic that is frequently found in a fruiting condition. Some have been demonstrated to have been borne upon Psaronius stems and this is probable of the majority. The fructifications are of a variety of types. Those known as *Asterotheca* had large syngangia in two rows one on either side of the median vein on the under surface of the pinnules each consisting of five or six sac-like confluent sporangia forming a close ring. Other confluent syngangia known as *Ptychocarpus* characterize an Upper Carboniferous and Permian series of Pecopterids. These syngangia consist of five to eight Sporangia united laterally to form a close ring and adherent to a central receptacle and embedded in continuous enveloping tissue. They discharged their very numerous small spores through apical pores and greatly resemble the arrangement in the modern genus *Kaulfussia*. A third Paleozoic type is *Danaëites* and *Parapecopteris* in which each pinnule bore two continuous rows of ovoid sporangia more or less united and embedded in the lamina and opening by apical pores. A fourth type known as *Scolecopteris* shows the sori in two rows and consisting of four or five long-pointed pendant sporangia more or less confluent proximad united internally for about one-third their length to a central stalk, suggestive of the modern genera *Marattia*, *Kaulfussia* and *Angiopteris*, particularly the first. Other fructifications (Grand'Eurya, *Dactylothea*) have partially or entirely free exammulate sporangia. Many other supposed marattiaceous fructifications have been described from the Paleozoic rocks, e.g., *Hawlea*, *Urnatopteris*, *Renaultia*, *Sphyropteris* and *Discopteris*.

The Marattiales were represented in Triassic floras by numerous widespread forms variously referred to the genera *Marattia*, *Marattiopsis*, *Angiopteridium*, *Angiopteris*, *Danaë*, *Danaëopsis*, *Pseudodanaëopsis*, *Asterotheca*, *Taniopteris* and *Macrotaniopteris*. They occur on all the continents and make a particularly large display in the late Triassic (Keuper and Rhaetic) at which time palustrine, often coal-forming, conditions with apparently identical species of plants occur from the Arctic to the Antarctic and from Tonkin and Australia to Virginia, California and Chile. The identity of these Triassic Marattiales with existing forms rests on the form and venation of the fronds, the arrangement and structure of the sporangia, and even the spores.

The Marattiales were less dominant in the overlying Jurassic and they were still more

reduced during the Lower Cretaceous (*Angiopteridium*, *Nathorstia*, *Taniopteris*).

Subsequent to Lower Cretaceous times Marattiaceous remains are infrequent although occasionally brought to light in the Upper Cretaceous and Tertiary. A *Marattia* is described from the English Eocene and a second from the French Oligocene.

The order Osmundales includes the two recent genera *Osmunda* and *Todea* with large sporangia arranged in small groups, in linear and often confluent sori, or clustered around the axis of the much reduced fertile pinnæ. An annulus is represented by a group of thick-walled cells below the apex. These stand somewhat apart from the balance of existing ferns and are wide-ranging forms, some of which are found on all the continents, *Osmunda* being cosmopolitan and *Todea* antipodean. Aside from morphological considerations the evidence that the Osmundales constitute a relatively primitive line of fern evolution is furnished by impressions like *Todea Lippoldi* Stur from the Lower Carboniferous of Silesia, petrified sporangia such as *Todeopsis primæva* Renault from a similar French horizon or *Sturiella* from the German Upper Carboniferous, and finally by the phylogenetic series of petrified stems described by Kidston and Gwynne Vaughan, among which the genera *Bathypteris*, *Anomorphæa*, *Thamnopteris* and *Zalleskya* come from the Upper Permian (Thuringian) of the Ural region. Space does not permit a description of their histology but it may be pointed out that the order appears to have been derived from an ancestor with a solid stele like the Cœnopterian species *Diplolabis Ræmeri* and to have undergone an evolution more or less paralleling that of the *Zygopteraceæ*. The stem is continued by Jurassic and Lower Cretaceous species of Osmundites from South Africa, New Zealand and Canada, and by Tertiary species from England, South America and Hungary. Impressions of both sterile and fertile fronds allied to *Todea* are abundant and cosmopolitan in the late Triassic and Jurassic and continue into the Cretaceous, while *Osmunda*-like fronds are common throughout the Lower and Upper Cretaceous and Tertiary in all parts of the world.

A class of ferns including the existing heterosporous *Rhizocarps* or so-called water fern includes the order Hydropterales and possibly an extinct order the Sagenopterales. The two existing families, *Marsiliaceæ* and *Salviniaceæ*, are small, more or less widespread aquatic forms. The *Salviniaceæ* contain the genera *Azolla* and *Salvinia* with between 15 and 20 existing species of the warmer regions and the leaves of the latter, not appreciably different from those of the existing species, are found throughout the Tertiary period.

The *Marsiliaceæ* consists of three genera—the monotypic Brazilian *Regnellidium*, *Pilularia* with about six species and *Marsilia* with over 50 widely distributed existing species. The last has been found fossil as early as the Upper Cretaceous but is rare and more or less uncertain in the fossil state. The extinct genus *Sagenopteris* is based for the most part on groups of two to five large asymmetrical reticulate veined pinnules borne digitately at the apex of a long and rather stout stipe, and

found as impressions from the Triassic to the Cretaceous. Associated with some of the older forms are oval or spherical bodies thought to represent sporocarps.

The remainder of the living and fossil ferns excepting certain illy understood extinct types such as the Devonian and Lower Carboniferous Archæopteridæ and the Mesozoic Tempskya, may be grouped together in the Leptosporangiate or Eufilicalean order Polypodiales, although there is some evidence for recognizing the Gleicheniales and Matoniales as independent orders.

The Polypodiales embrace the great majority of living ferns and include the most specialized and abundant families. Without taking space to give their diagnostic characters, it will be desirable as well as interesting to glance at the geological record of the various families.

The family Schizæaceæ with between 75 and 100 existing, mostly tropical species, segregated into the genera Schizæa, Lygodium, Mohria and Anemia, appears to be present as early as the Upper Carboniferous in the genus Senftenbergia. Triassic forms are not certainly recognized but the Jurassic genus Klukia shows fructifications that render its reference to this family conclusive. During the Lower Cretaceous the genus Ruffordia of Europe and America appears to represent the genus Anemi while Schizæopsis, found in a fruiting condition in the Lower Cretaceous of Virginia, represents Schizæa. The genus Acrostichopteris, based upon sterile fronds which range from the bottom to the top of the lower Cretaceous, and found in both Europe and America also almost certainly represents an extinct type belonging to this family. In the Upper Cretaceous petrified sporangia of the Schizæa type have been found in Japan (*Schizæopteris mesozoica*). Undoubted species are common and widespread during the Tertiary.

The family Gleicheniaceæ embraces about 100 tropical and subtropical gregarious species now segregated to form the genera Gleichenia, Platyzoma, Dicranopteris and Stromatopteris—the last monotypic on New Caledonia and Platyzoma monotypic in northern Australia. The family is evidently an old one and appears to be present as early as the Carboniferous in the genus Oligocarpia which had sphenopteroid foliage and circular sori consisting of from 6 to 10 pyriform sporangia with a complete transverse annulus (Zeiller 1888, *vide* Scott, 1908). The Carboniferous genus Gleichenites Göppert and the dichotomous branching genera Mariopteris Zeiller and Diplothemema Stur are all now considered as probable Pteridospermophytes and it is evident that the Gleichenoid habit of growth was common in both Paleozoic and Mesozoic and is without especial bearing on botanical relationship. The family is not known to have been abundant in the Triassic or Jurassic, the Keuper genus Mertensides of Fontaine being often referred to the Marattiales. A species of Gleichenia with well-marked fructifications is, however, recorded from the Keuper of Switzerland and the genus is known from the Rhetian of Franconia. Jurassic species are recorded from California, India, Italy and Poland. Throughout the Cretaceous Gleichenia becomes almost worldwide in its

distribution. While the number of species has probably been excessively multiplied the records show 15 Lower Cretaceous forms. No less than 25 different species have been recorded from the Upper Cretaceous. Gleichenia becomes much less abundant in the Tertiary and all of the known Tertiary records are pre-Miocene. Four species are known—two Oligocene species in Saxony, an Eocene or Oligocene species in Nevada and a middle Eocene species in the south of England.

The family Matoniaceæ, with but two existing species of Borneo and the Malay Peninsula, was prominent in older Mesozoic floras from the Upper Triassic through the Jurassic, at which time it was represented by a variety of widespread species referred to the genera Lacopteris and Matonidium. Still more interesting is the family Dipteriaceæ with a single existing genus, Dipteris, with but four species confined to the Malayasian region and found growing in association with Matonia. The Dipteriaceæ became dominant slightly earlier than the Matoniaceæ and the magnificent fronds of some of the species are exceedingly common in the Triassic at which time the genera Dictyophyllum, Clathropteris, Thaumatopteris and Camptopteris are represented. They had lyre-shaped fronds of large size, consisting of many separate or slightly united, serrate-margined and netted-veined pinnules, arranged digitately on a forking stipe. Clathropteris and Dictyophyllum survived into the succeeding Jurassic where they were on the wane, becoming replaced in the Cretaceous by forms more like the modern Dipteris and referred to the genus Protorhipis (Hausmania).

The family Hymenophyllaceæ, comprising the existing filmy ferns, is practically unknown in the fossil record although several Paleozoic genera (Hymenophyllites, Rhodea, Acrocarpus) have been referred to it upon insufficient grounds.

Without mentioning the various small modern families unknown in the fossil state there remains the two families Cyathaceæ and Polypodiaceæ. The former are almost exclusively tree ferns in the modern flora. They are represented in the Mesozoic by Coniopteris, Dicksonia and Thyrsopteris, to which Dennstædia is added in the Tertiary.

The Polypodiaceæ, which comprise the bulk of existing ferns and exhibit a very great variety in form and habit, are relatively modern. Some at least of the older Mesozoic species which are referred to the form genus Cladophlebis belong to this family. Cladophlebis which appeared in the Triassic became cosmopolitan in the Jurassic and Lower Cretaceous where it was associated with species of Onychiopsis, Asplenium, Dryopterites, etc. Pteris, Onoclea and other genera are added in the Upper Cretaceous and a great variety of generic types appear in the Tertiary (Adiantum, Polypodium, Acrostichum, Oleandra, Woodwardia, etc.).

Arthrophyta.—The Arthrophyta constitute a well-marked phylum and comprise plants ranging in size from herbaceous forms to large trees and found from the oldest horizons containing land plants down to the present. They are characterized by invariably articulated and prevailingly-ribbed stems, the leaves in whorls (verticillate) at the nodes and free or more or

less connate, dichotomously compound in the earlier groups (Pseudoborniales, Protocalamariaceae), palmately lacinate in some Sphenophyllae, progressively reduced during the history of the phylum until in the modern forms the stems and branches perform most of the photosynthesis. They are all sporangiophoric and strobiloid, although there is a considerable range of variation in morphological and histological details. Some are homosporous and others heterosporous. The phylum is unique in that it attained its maximum development in the Paleozoic and has been practically unrepresented since Triassic times except by the single genus *Equisetum*, which survives to the present with less than two score ubiquitous and rather uniform species. The phylum appears to have been of Pteridophytic origin and to have been primitively megaphyllous. Taxonomically it corresponds rather closely with the Articulatae of Lignier and the Sphenopsida of Scott. As known at the present time it consists of two classes—the Sphenophyllae and the Calamariæ, and the latter includes three rather well-defined groups or orders, namely—the Pseudoborniales, the Equisetales and the Calamariales—the last including two families, the Protocalamariaceae and the Calamariaceae.

The most primitive of these subordinate groups constitutes the class and single order Sphenophyllales of the class Sphenophyllae. This was a synthetic alliance of mostly small forms that combined certain fern characters with those of the Calamariæ on the one hand and the Lepidophyta on the other. They are regarded as representing the specialized descendants of a pro-Sphenophyllum stock which was more truly intermediate between the Arthrophyta and Lepidophyta and which is supposed to have flourished in pre-Devonian.

Sphenophyllum ranged from the Devonian to the Permian and was practically cosmopolitan except for its partial extinction in Gondwana Land during and immediately subsequent to the Lower Permian glaciation. A considerable number of rather uniform species based for the most part upon the impressions of the slender jointed ribbed stems with nodal whorls of cuneate leaves (hence the generic name) are known. The ribs did not alternate at the nodes and consequently the leaves of successive whorls were superposed and not alternating. The leaves, normally six to a whorl and cuneate with entire or toothed apical margins, were frequently dichotomously lacinate and in some forms with numerous narrow leaves in each whorl these are legitimately regarded as corresponding to the lacinate segments of the digitately-leaved species. The stems branched frequently at the nodes. The fructifications were fairly large cones, superficially resembling those of calamites. The stem anatomy was characteristic and sufficiently unique. In the centre there was a triangular strand of primary wood without any pith or parenchyma and either triarch or hexarch in structure, with the protoxylem or primitive spiral elements at the angles and centripetal in its development. The spiral elements sometimes pass into articulate tracheids and the later and more central tracheids are pitted. Secondary wood formation commenced early in the ontogeny by the activity of a normal cambium. The secondary wood

had its elements very regularly arranged and consisted of radial series of large tracheids with bordered pits, chiefly on their radial walls. Interspersed among the tracheids were vertical strands of parenchyma connected radially by short cells or strands that did not form continuous medullary rays. Beyond the normal cambium was the phloem surrounded by internal periderm formed by a phellogen, first in the cortex and subsequently passing inward until it arose in the phloem itself. In *Sphenophyllum insigne*, a Lower Carboniferous form of Britain and Silesia, the stem was rather larger than the average although still not over a centimeter in diameter, and differed in having continuous medullary rays, so that the complicated system of vertical and radial parenchyma of the later forms may have been a derived rather than a primitive feature. The leaf anatomy presents no unusual characters except its strong mechanical construction, thus precluding the idea advanced by some botanists that the Sphenophylla were aquatic forms. The root anatomy shows no features of special interest. At least seven types of cone organization are known, indicating generic differences unsuspected from the external appearance or vegetative habits of the plants. In some fructifications the slender cones consisted of a central axis with whorls of proximally connate bracts, the latter with long imbricated pointed tips. Each bract bore two slender, one long and the other short, stalked sporangiophores, so that there were two concentric series to each whorl of bracts. A single pendulous sporangium was borne at the tip of each sporangiophore. The spores were somewhat variable in size which has been interpreted as indicating incipient heterospory and appear to have been all of one kind. A second type (Bowmannites) had similarly connate whorls of imbricated bracts, each of which enclosed three concentric verticils of short-stalked bisporangiate sporangiophores. A third type (*S. fertils*) had peltate bisporangiate sporangiophores but was unique in that both the dorsal and ventral lobes were fertile, i.e., the sterile bracts or morphologically dorsal foliar lobes were replaced by sporangia-bearing fertile lobes. A fourth type (*S. majus*) had lax cones made up of repeatedly forked bracts each with four sessile or very short-stalked sporangia on their upper (morphologically ventral) surface. A fifth type (*S. trichomatosum*) had a single sporangium near the axis on each bract. In a sixth form (*S. marginatum*) the sporangiophores were borne on the axis instead of on the bracts. A seventh and remarkably complicated type known as *Cheirostrobis* is often made the type of a distinct family, the *Cheirostrobaceae*. It is unfortunately known only from a few petrified cones from the base of the Lower Carboniferous of Scotland. These cones were large, three to four centimeters in diameter and about 10 centimeters long, and consisted of closely packed verticils of compound sporophylls, each consisting of three upper (ventral) fertile lobes and three lower (dorsal) sterile lobes. Each of the fertile lobes or sporangiophores bore four radially elongated homosporous sporangia. The second class of arthrophytes—the Calamariæ, include three orders, the ancient Pseudoborniales, the Calamariæales comprising the large and diversified calam-

ites of the Paleozoic and the Equisetales, sparingly represented in the Paleozoic, somewhat more abundant in the Mesozoic and represented in the existing floras as the sole survivors of the whole arthrophyte phylum. The Pseudoborniales are imperfectly known, being based upon impressions from the upper Devonian of Bear Island. The main stems were of considerable size, reaching 10 centimeters in diameter, with non-alternating ribs. The leaves, of relatively larger size, were in whorls (probably in fours) short-stalked and palmately and repeatedly dichotomous. The fructifications were long, lax cones with whorled sporophylls resembling reduced vegetative leaves and the sporophylls bore sporangia on their lower surfaces. These important plants, unfortunately too little known, show decisive evidence of megaphyllus ancestry. The Protocalamariaceæ, which are common in the Devonian and Lower Carboniferous, occurring as late as the Pottsville formation of the Upper Carboniferous, are generally referred to the genus *Archæocalamites*, although the terms *Bornia*, *Protocalamites*, *Asterocalamites*, etc., have also been used. The stems most frequently preserved as casts were often of considerable size; they show low, flat, non-alternating ribs separated by shallow furrows; the internodes were of unequal lengths and the lateral branches were irregularly grouped at some and not at other nodes. The leaves were free and in whorls; they were narrow and lanceolate or repeatedly dichotomous with linear or filiform segments. According to Renault the pith cavity was large and surrounded by a woody cylinder of wedge-shaped groups of tracheids with secondary rays. A carinal canal was located at the apex of each primary group and the primary rays were shut off by interfascicular wood early in the course of secondary thickening. In a stem from the basal Carboniferous of Scotland a considerable arc of centripetal wood was formed inside the carinal canal. Such incomplete accounts as are available indicate that the cones may have exhibited variations comparable with those among the *Sphenophyllas*. In the cones described by Renault there were no sterile bracts and each sporangiophore bore four sporangia, while in other cones (*Pothocites*) sterile bracts appear to have been more or less developed. The leaves suggest the Pseudoborniales and some of the *Sphenophyllæ*; the stele was like that of a calamite, while the absence of sterile bracts in some of the cones suggests the Equisetales. There can be no doubt but that the Protocalamariaceæ represent a more synthetic group than the Calamariaceæ although probably ancestral to them and the Equisetales. The family Calamariaceæ was one of the dominant groups of plants during the Carboniferous and various of its members often reached a large size with a corresponding complexity of structure. Pith casts upwards of 30 feet in length and 12 inches in diameter have been recorded and Grand'Eury estimated the height of some of the French calamites as about 100 feet and with a trunk diameter of several feet. Secondary wood was usually formed, although the common mode of preservation was as casts of the fistular medullary cavity. The vascular bundles usually alternated at the nodes. The

foliage of the Carboniferous forms comprised two main types, namely, *Asterophyllites*, in which the leaves were linear univeined and generally free from the others of the nodal whorl. This type of foliage was very common and it would seem that the bulk of the calamites had foliage of this sort. The second type of foliage known as *Annularia* was like the former in habit but the leaves were relatively broader, of unequal lengths in each whorl, and appear to have been slightly connate proximad. It is impossible to correlate foliar branches with stem casts, cones and structural material, so that while all of the parts of the calamites are well known, in different examples it is necessary to maintain these different categories for the different classes of remains. The foliage varied considerably not only from species to species, but on the same plant, and while the two foregoing types constitute useful form genera it is not always possible to differentiate sharply between them. The genus *Nematophyllum* of the West Virginia Permian shows greatly elongated linear leaves from 10 to 20 in a whorl and suggests a modification in the direction of the Triassic *Schizoneura* and *Neocalamites*. *Schizoneura*, a type of the Permian and Triassic, had leaves which were at first united in a sheath or in several broad sheath segments that subsequently split into a varying number of multiple-veined divisions. *Neocalamites* of the Triassic had free univeined leaves in some of the late Triassic species greatly resembling those of *Annularia*. *Phyllothea*, a Permian and early Mesozoic type, had acicular slightly connate univeined leaves and sporangia borne on peltate sporangiophores alternating with whorls of sterile bracts. *Nematophyllum*, *Schizoneura*, *Neocalamites* and *Phyllothea* are all based upon impressions so that a knowledge of the structure or the details of organization of their fructifications is unfortunately wanting. Structurally calamite leaves show a central trace surrounded by a broad zone of mesophyll. Several generic types of calamites have been based upon stem anatomy. These include *Arthropitys* (the Calamites var. of British botanists) in which the pith was large and hollow except peripherally, with persistent diaphragms at the nodes. Surrounding the pith was a ring of collateral vascular bundles, the protoxylem in all but the youngest stems being disorganized to form longitudinal passages known as carinal canals. The wood was entirely centrifugal in its development. Secondary wood formation started early and consisted of scalariform or radially pitted tracheids and variable rays which continued with undiminished width through the vascular cylinder or tapered outward or were abruptly shut off by interfascicular wood. The cortex consisted of an inner thin-walled zone of cells and an outer denser zone in which there was a very great development of periderm. The courses of the leaf traces was somewhat varied and more complicated than in the Equisetales, otherwise *Arthropitys* was much like an *Equisetum* with the addition of secondary thickening. A second type known as *Anthrodendron* and confined to the British coal measures had a thin zone of wood in which the primary bundles were widely separated by the principal rays which consisted of elongated fibrous elements (prosenchyma) within which there were

secondary rays of parenchyma like those of the secondary wood. In the latter the tracheids are reticulate and the infra nodal canals very large. A third type, *Calamodendron*, of the European Upper Carboniferous and Permian, had radial bands of prosenchyma containing secondary rays between the normal rays and the radial bands of secondary wood. The roots of calamites preserved as impressions, of widespread occurrence, are known as *Pinnularia*. Structural root material, known as *Astromylon*, shows a usually persistent pith surrounded by a ring of centripetally developed primary wood alternating with groups of primary phloem. The

alternate equidistantly with usually twice as numerous sterile bracts, connate or free basally flexed and imbricated proximally. In some species the spores appear to be all of one kind (homosporous), although they are somewhat unequally developed. Other species were heterosporous although both microspores and megaspores were borne in the same region of the cone. Still other species had radial sterile plates connecting the sporangiophores with the adjacent bracts, thus enclosing each group of four sporangia in a radial compartment. Although the sporangiophores were borne on the cone axis midway between the whorls of sterile

FIG. 3.—Geological History of the Arthrophyta. [Courtesy of Johns Hopkins University]

zone of secondary wood was wide; the endodermis appears to have been double; and the cortex was very thick with large lacunar intercellular spaces, denoting a swampy or aquatic habitat. Great numbers of a variety of calamite cones are known from impressions, as the large cones of *Macrostachya*, the more openly constructed cones of *Huttonia*, and the curious cones of *Cingularia*. The two types *Calamostachya* (*Volkmania*) and *Palæostachya* are also represented by a considerable amount of petrified material with the structure preserved. In *Calamostachya* the whorls of peltate sporangiophores, each bearing four pendant sporangia

bracts their supply bundles have a common origin forking at the nodes and that of the sporangiophore passing upward more or less across the interval of the internode and then bending downward and entering the sporangiophore, thus indicating that although widely removed from the bracts the sporangiophores were morphologically their ventral appendages as in *Sphenophyllum*. *Calamostachya* is usually, but not invariably, associated with the *Asterophyllites* type of foliage. Petrified material of *Palæostachya* is less common than that of *Calamostachya*. The former cones differ in having the sporangiophores inserted in the axils

of the bracts and inclined upward—features usually discernible in impression material. The bracts were imbricated and more or less connate proximad. The sporangiophores, half as numerous as the bracts, bore four pendant sporangia from their peltate tips. Some cones appear to have been homosporous and others heterosporous. It has been commonly assumed from the axillary position of the sporangiophores that *Palæostachya* was more primitive than *Calamostachya*, but in one species at least of the former the supply bundles pursue a similar at first ascending and subsequently descending course similar to what obtains in *Calamostachya*.

the bracts. The sporangiophores were ligulate and divided distad and each division bore two large pendant sporangia.

The final order of the Calamariæ, the Equisetales, consists of the single family Equisetaceæ and comprises at the present time the single genus *Equisetum* with 25 to 30 rather uniform, widely distributed, mostly small and chiefly temperate species of scouring rushes or mares' tails. The cones are terminal on fertile shoots or on branches from the vegetative shoots and entirely lack sterile bracts. They consist of peltate sporangiophores carrying from five to 10 homosporous sporangia. The rhizomes or

FIG. 4.—Mutual Relationships of the Lepidophyta.

Some of the *Palæostachya* cones were of large size and they are usually associated with the *Annularia* type of foliage. *Macrostachya* is the name applied to exceedingly large cones of calamites preserved as impressions. They show considerable variation and are said to have been heterosporous. *Huttonia* includes large cones somewhat resembling those of *Macrostachya* but more open and characterized by a disc-like protective flange pendant from the bract whorls. *Cingularia* comprises long and lax cones with widely spaced whorls of coherent bracts at right angles to the axis, subtended by whorls of non-alternating sporangiophores, equal in number to

underground stems of the species with annual shoots commonly form tubers and these often occur abundantly as fossils as in the Lower Cretaceous of Maryland. The Equisetales were represented by a number of small and imperfectly known Paleozoic species referred to the genus *Equisetites*. During the Triassic they were represented throughout the world by stem casts, often of large size, with alternating ribbed stems and the leaves united into sheaths at the nodes. They continued as not uncommon types throughout the Jurassic in all parts of the world, decreasing gradually in size and abundance during the later Mesozoic until their status and

size in the Cenozoic floras was much as in the existing flora.

The generalized geological ranges of the various arthrophyte groups as well as their relative importance at different periods and their filiation are shown in the accompanying diagram (Fig. 3).

Lepidophyta.—The Lepidophyta occupy a somewhat isolated position among vascular plants although there are not wanting students who connect them with the Hepaticæ or the Sphenophyllales on the one hand, and with the seed-bearing plants on the other. The phylum includes the tiny existing quillworts and herbaceous clubmosses as well as the often gigantic Lepidodendrales which occupied such a prominent position in Paleozoic floras.

Features which serve to unite the somewhat diverse members of this phylum are the small simple leaves, spirally arranged and not verticillate as in the Arthrophyta. All the known Lepidophytes are microphyllous, the only departure from a simple type of leaf being the double leaftrace in the Paleozoic Sigillariopsis. A second consistent feature is the presence of branch gaps and the absence of leaf gaps in the vascular cylinder, which is thus cladophonic, with an exarch protostele. A third feature is the apparently simple relation between the sporangium and the sporophyll, which can be interpreted as due to progressive sterilization according to Bower's well-known theory, or may be explained as a reduction from the same or similar sporangiophoric ancestors that give rise to the Arthrophytes phylum.

The Lepidophyta are prevailing strobiloid and are known from the Devonian to the present. Some are homosporous, other heterosporous while still other Paleozoic forms had practically crossed the boundary that separates spore production from seed formation. Further details are best given in the discussion of the various types which follow. The mutual relationships of the different members of the phylum are shown in the accompanying diagram (Fig. 4) and in the light of present knowledge may be expressed in tabular form in the following manner:

Order Lypidodendrales	{	Family Bothrodendraceæ
		" Lepidodendraceæ
		" Sigillariaceæ
Order Lycopodiales	{	Family Lycopodiaceæ
		" Selaginellaceæ
Order Isoetales—Family Isoetaceæ		
Order Psilotales—Family Psilotaceæ		

It will make for clearness to consider the existing forms and their fossil representatives before describing the wholly extinct Lepidodendrales. The Lycopodiales comprise two families. The Lycopodiaceæ include two genera, *Lycopodium* and *Phylloglossum*. *Lycopodium* has about 100 widely distributed existing species of mostly perennial-erect or trailing herbaceous forms of shaded woods, marshes, etc., some tropical species, epiphytes. But one kind of spores are formed and the sporangia are borne on or in the axils of scarcely modified foliage leaves more or less distinctly aggregated into strobili.

Fossil species of *Lycopodium* or *Lycopodites*, which is often preferred as a less definite name, are especially liable to be confused with the foliage of some of the Lepidodendrales or Coniferophytes unless represented by fructifica-

tions. Among the rather numerous forms referred to *Lycopodites* and scarcely different from the existing forms may be mentioned *L. Stockii*, Kidston from the Lower Carboniferous, *L. Gutbieri*, Göpp, and *L. Reidii*, Penhallow from the Devonian; *L. macrophyllus*, Goldenberg; *L. Zeilleri*, Halle from the Upper Carboniferous; *L. lanceolatus* (Brodie) and *L. Scanicus*, Nath, from the Upper Triassic; *L. falcatus*, *L.* and *H. L. tenerrimus*, Herr; *L. victoriae*, Seward from the Jurassic; and *L. cretaceum*, Berry from the Upper Cretaceous. While *Lycopodium* like forms were never apparently very different from what they are at present, they represent a very ancient line and were present as a minor element associated with the diversified arboreal Lepidophyte flora of the Paleozoic.

The genus *Phylloglossum* contains a single reduced species of Australia and New Zealand and is unknown in the fossil state.

The second family, the Selaginellaceæ, consists of the single genus *Selaginella* with about 500 species of mostly mesophytic small plants not differing greatly from the Lycopodiaceæ except that after the mother cell stage the spores differentiate into micro and megaspores. The foliage is usually dimorphic and both foliage leaves and sporophylls have a ligule. The cones are not highly differentiated from the vegetative leaves. Sometimes but one megaspore is developed in a sporangium and fertilization may take place before shedding, thus illustrating steps in the acquisition of the seed habit. Fossil species of *Selaginella*, unless they are fruiting, are not certainly distinguishable from *Lycopodites*, nevertheless several undoubted species have been recorded from the Carboniferous (*Selaginellites Suissei* Zeiller, *S. primævus* Goldenberg, *S. elongatus* Gold, *S. ciliatus* Kidst). Less authentic species are recorded from Mesozoic and Cenozoic deposits of widely scattered regions.

The second order, the Isoetales, consists of the single genus *Isoetes* with about 60 existing aquatic or palustrine species with a reduced tuberous stem and a crowded rosette of grass-like ligulate leaves, which are relatively larger than in the majority of Lepidophytes. Microspores and megaspores are produced, both characterized by their large size and by the formation of trabeculæ or strands of sterile tissue often completely dividing the sporangia cavity. Secondary thickening occurs and morphological resemblance to the ancient Sigillaris and modern Monocotyledons have frequently been insisted upon although without logical basis. Fossil forms are exceedingly rare, Saporta recorded a form from the Lower Cretaceous (Barremian) of Portugal (*Isoetes Choffati*). Aside from untrustworthy records *Isoetes* occurs in the Oligocene of France and the Miocene of Switzerland.

The third order, the Psilotales, is one which has excited a great deal of discussion. It comprises the two genera *Psilotum* and *Tmesipteris*; the former with two species of both tropics and the latter with a single Australasian species, although more are frequently recognized. Both genera are considered to be more or less saprophytic. The sporophylls of *Psilotum* consist of a much shortened bifurcated axis bearing a bilocular or trilocular synangium producing but one kind of spores. In *Tmesipteris* the

sporophylls alternating with foliage leaves or more or less zonal in their development, consist of a short axis terminating in a pair of lanceolate lobes and bearing adaxially an elongated bilocular slightly stalked synangium, and producing but one kind of spores. Both genera show a decided tendency toward repeated branching of the sporophylls, a feature much emphasized by Thomas, Scott and Bower, but believed by the writer to be without significance. Whether the sporophyll be regarded as morphologically a branch or a leaf is disputed.

Those who accept the latter view regard the Psilotales as sporangiophoric and closely related to the Sphenophyllales. Others consider that the necessities of nutrition of large sporangia with many spores resulted in the formation of sterile plates such as occur in *Isoetes* and in the sporangia of some of the *Lepidodendrales* and regard the bi- or trilocular sporangia of the Psilotales as septate unilocular sporangia. The view that these masses of sterile tissue may represent vestiges derived from sporangiophoric ancestry has not been sufficiently emphasized and will be referred to in a subsequent paragraph. Meanwhile it may be said that the action of Scott and others in separating the Psilotales from the Lepidophytes and grouping them with the Arthrophytes is greatly to be deprecated. The fossil history of the Psilotales is unknown. Various fragmentary specimens described as Psilotales are without value. Among the doubtful forms that have been related on the Psilotales are the Devonian genera *Psilophyton*, *Dimeripteris* and *Pseudosporochus* and the Permian genus *Gomphostrobus*.

The order *Lepidodendrales* merits a more extended consideration. It consists of three well-marked families, the *Bothrodendraceæ*, *Lepidodendraceæ* and *Sigillariaceæ*, very prominent in Paleozoic floras. Although herbaceous remains are known the vast majority of the *Lepidodendrales* were arborescent and some of them reached a height of 100 feet or more. The most ancient of these families, the *Bothrodendraceæ*, unites in many respects the features that later characterized the *Sigillariaceæ* on the one hand and the *Lepidodendraceæ* on the other. The *Bothrodendraceæ* are especially characteristic and cosmopolitan during the Devonian and Lower Carboniferous. A number of generic types have been recognized although our information regarding them is vague in a good many particulars. *Bothrodendron*, or *Cyclostigma* as it has frequently been called, is not very different in appearance from some species of *Sigillaria*. The stems were dichotomously branched. Bolsters are usually wanting and the leaf scars are remote, small and circular or rhomboidal; they show a central leaf trace scar and two lateral parichnos scars; immediately above and close to the leaf scar is a small ligular pit. The leaves were small, linear lanceolate, univeined and more or less persistent. In one species (*B. punctatum*) the self-pruning of branches resulted in the large scarred impressions known as *Ulodendron*. The term *Rhytidodendron* has been used for some species and recently the genus *Proden-dron* has been proposed for certain forms from the Lower Carboniferous of Russia and Spitzbergen that were formerly referred to *Bothrodendron*. Anatomically the stems show either a small pith or a solid core of wood with ex-

ternal protoxylem. The secondary zone of wood was thin and the cortex was less differentiated than in the *Lepidodendrales*.

A cone, *Lepidostrobus Olryi* Zeiller, which is considered to have belonged to *Bothrodendron minutifolium* is of the usual *Lepidostrobus* type with elongated sporangia. A small cone with a histology that suggests its having been borne by *Bothrodendron mundum* lacks the radially elongated sporangia and instead has them extended upward inside the sharply flexed bracts and is conspicuously ligulate. It bore microsporangia in the distal and megasporangia in the proximal region. Another type of cone *Lepidostrobus Zeilleri*, which may belong to *Bothrodendron tenerrimum*, appears to lack sterile bracts.

Another genus, distinguished from *Bothrodendron* by the surface ornamentation of fine raised lines between the remote leaf scars, is *Pinakodendron*. Several species have been described and in one, *P. Ohmanni*, the megasporangia were borne on the basal adaxial faces of the sporophylls of the same size and form as the foliage leaves on certain parts of the branches but not terminal as were most *Lepidophyte* cones.

Other genera of somewhat doubtful affinity are *Leptophleum* in which the leaf scars are more crowded, and *Omphalophloios* in which rhomboidal bolsters were developed. *Leptophleum* occurs in the Devonian or Lower Carboniferous of North America, Europe, Asia and Spitzbergen while *Omphalophloios* is found in both America and Europe.

Other related forms are referred to the genus *Archæosigillarea* or *Protolopodendron*. The most remarkable of these is a large trunk from the Middle Devonian of New York, five meters in length and 38.5 centimeters in diameter at the swollen butt, and 12 centimeters in diameter at the distal end. In appearance the slender arching bifurcating branches with the subulate falcate persistent leaves gave it a weird aspect. The swollen base and tapering stem indicate some secondary thickening. At the base rootlets similar to these of *Stigmara* are preserved. The leaf cushions at the base are distant and irregular. Higher up they are in vertical rows on ribs separated by angular furrows as in *Sigillaria* while still higher up they pass gradually into typical rhomboidal spirally arranged *Lepidodendron* bolsters. The leaf scars are in the upper part of the bolsters, obovate in form or slightly cordate above, and show a subcentral leaftrace scar flanked by crescentic 'parachnoi' with a well-marked ligular pit immediately above the margin.

Protolopodendron thus unites the features of *Lepidodendron* and *Sigillaria* in one synthetic type and it seems probable that the majority of Devonian forms that have been referred to these two genera really represent *Protolopodendron*. Other species have been recorded from various European Devonian localities.

The majority of *Lepidodendrons* were tall trees reaching in some cases a height of 40 meters, with a straight shaft unbranched for a long distance above the ground, with a dense crown of dichotomously forked branches covered with crowded masses of long narrow simple spirally arranged leaves, and with large

terminal cones. The leaves were ultimately shed from the older portions of the trunk and the geometrically sculptured stems are among the commonest of Carboniferous fossils affording the characters by which several hundred species have been distinguished and utilized for stratigraphic purposes.

The essential features of the surface markings are of considerable importance. The leaf cushions or bolsters were crowded in spiral arrangement with angles above and below, and rounded sides (rhombic), always longer than broad and truncated above the middle where the abscission of the leaf occurred. The leaf scar is subcircular and shows three scars, a central one representing the leaf trace and laterals on each side known as parachnoi. Just above the leaf scar is a small triangular print left by the ligule, while below the leaf scar there are frequently two rounded prints or depressions on either side of the keel which like the parachnoi are tracts of thin-walled tissue which functioned as aerating tissue. Other markings of an ornamental character are frequently present on the bolsters. With the decay of the cortex the characteristic *Lepidodendron* features gradually become obliterated. If merely the epidermis is gone the resulting features are those of *Bergeria* once thought to represent an independent genus. If decay has removed part of the cortex the forms are known as *Aspidaria*, and if all of the outer cortex is gone showing the imbricated leaf-traces it is known as *Knorria*.

Anatomically the stem is monostelic with centripetal primary wood which may extend to the centre or enclose a pith. There is usually a considerable development of centrifugal secondary wood consisting of scalariform tracheids and medullary rays. Primary phloem has been recognized but there is some doubt regarding the presence of secondary phloem or of any persistent cambium. In forms that have not been demonstrated to have formed secondary wood secondary thickening takes place in the outer cortex through the development of a periderm.

Leaf traces, collateral in structure, pass off from the stele without leaving any gaps and pass obliquely through the cortex to the leaves, each leaf receiving a single bundle. The cortex is of great thickness and variable according to age and species. Usually there is an inner parenchymatous zone poorly preserved. The outer cortex consists of thicker walled elements, usually with an enormous development of pheloderm, which served for mechanical support.

The leaves had a single central vascular bundle surrounded by a sheath of transfusion tissue and the stomata were commonly restricted to two deep grooves on the lower surface. What corresponds to the roots in higher plants are peculiar organs known as *Stigmaria*, which as casts or impressions are among the commonest Coal Measure fossils, particularly in the underclays beneath the coal seams. In complete specimens the main axis is seen to divide into four main forks which run horizontally and branch dichotomously. The surface is smooth or irregularly wrinkled and covered with well-spaced umbilicate scars to which in well-preserved material cylindrical radiating rootlets are seen to diverge. These are slightly constricted at the base and lack root hairs. The

main axis consists of a central pith, a ring of centrifugal wood accompanied by phloem and surrounded by a cortex with abundant periderm. Sometimes no distinction between primary and secondary wood is observable while in other specimens centripetal primary wood is present. The rootlets show a different anatomical arrangement each containing a monarch stele with radial vascular strands connecting the protoxylem with groups of cortical tracheids. They arise from the inner margin of the primary wood although the outer cortex is continuous with that of the main axis.

Stigmaria have frequently been found attached to both *Lepidodendron* and *Sigillaria* trunks. There has been much discussion regarding the morphological nature of *Stigmaria* since they do not conform to the usual morphology of true roots, but whatever their morphological homologies, physiologically they are roots.

The fructifications of the *Lepidodendraceæ* have been described under a variety of generic names, the most common being *Lepidostrobus*. *Lepidostrobus* had an axis similar anatomically to a vegetative twig and bore numerous spirally arranged sporophylls each bearing a single, very large radially elongated sporangium on its adaxial surface. The sporophyll had an up-turned blade and these formed an imbricated protective surface. Between the sporangium and the blade a ligule was present. It seems probable that the *Lepidodendrons* were always heterosporous, the two kinds of spores being produced on different parts of the same cone or upon different cones. The microspores were small, tetrahedral in form and very plentiful. The megaspores were relatively very large, few in number, tetrahedral in form, with a hairy surface and commonly opening by apical flaps. The prothallus within the megaspore is occasionally preserved and even archegonia have been recognized. In another cone genus, *Spencerites*, the sporangia were united to the sporophyll by a distal neck and the spores were winged. In some *Lepidodendron* cones large masses of sterile tissue are developed within the sporangia suggesting a vestigial sporangiophore and in *Mazocarpon* the large sausage-shaped megaspores are embedded in a solid parenchymatous tissue.

Still another type of *Lepidodendron* fructification was *Cantheliophorus* in which the sporophylls were commonly deciduous. Each sporophyll bore two large sporangia separated by a median sterile plate interpreted as representing the sporangiophore of the ancestral *prosphephenophyllum* stock.

The vast majority of stem impressions represent minor variations of the common *Lepidodendron* type. In the genus *Lepidophloios* the bolsters were very prominent and became recumbent in old age so that the normal leaf scar appears to be at the base. The *Halonia* branches with their spirally stalked deciduous cones appertain particularly to *Lepidophloios*, which, anatomically was, exactly like *Lepidodendron*.

The *Sigillariaceæ* were much like the *Lepidodendrons* in essential features but different considerably in habit. They attained their maximum development in the Upper Carboniferous and gradually waned during the Permian although they appear to have survived into the

Lower Triassic. The trunks were generally massive and for the most part unbranched, giving them a peculiar appearance and at one time suggesting a relationship with the cycadophytes, since discredited. Stem impressions, which, like those of *Lepidodendron*, are exceedingly common throughout the Coal Measures, can readily be distinguished by their vertically arranged scars often on prominent ribs, by the slight development of bolsters and by the scars being wider than high with the angles at the sides and rounded above and below. Very many species have been described and the variations observed are very useful for stratigraphic purposes and have resulted in an elaborate analysis of the types of surface ornamentation. These fall naturally into two main groups — the *Eusigillariae* with ribbed stems and the *Sub-sigillariae* with smooth stems.

The *Eusigillariae* show broad longitudinal ribs separated by furrows and are segregated into two subordinate groups, i.e., *Favularia*, in which the ribs are separated by zigzag furrows and the scars transverse furrows and *Rhytidolepis*, in which the ribs are separated by straight furrows and are often much broader than the close set or spaced scars. Where the furrows are broad and intercalated narrow ribs without leaf scars are developed the forms are sometimes set apart under the name *Polleriana*, and when transverse furrows appear the forms are grouped under the name *Tasselata*.

Various stages of preservation yield characteristic surface features thought to indicate distinct genera by the older student but useful now as descriptive terms. Thus when partially decorticated the inwardly enlarging strands of *aerochyma* result in vertical rows of pairs of large mammillae and such stems have been called *Syringodendron*. Petrified material of *Sigillaria* is rarely found. The pith was very large and the vascular cylinder thin and sometimes broken up into separate bundles. Tracheids reticulate or scalariform increasing in size centripetally. Secondary wood consisting of radially arranged scalariform and pitted tracheids, centrifugal in development with narrow medullary rays. Cortex was thick with an inner soft zone and an outer mechanical zone as in *Lepidodendraceae*. The leaftraces had an inner centripetal primary strand surrounded by a centrifugal secondary zone. The leaves are much like those of *Lepidodendron* with a central concentric vascular strand surrounded by a considerable development of transfusion tissue. In some instances the strand is double. The cuticle was dense and the stomata were confined to the two furrows on the lower side which were clothed with multicellular hairs.

The cones of *Sigillaria*, usually going by the name of *Sigillariostrobus*, are common as impressions, but are practically unknown in a petrified condition. They were often very large, being as much as five or six centimeters in diameter in *S. nobilis*. They agree in having long peduncles covered with needle-like bracts. The fertile part bears crowded sporophylls of somewhat variable shape with flexed and imbricated distal blades. The sporangia were sometimes attached for nearly their whole length to the adaxial face of the sporophyll while in other cases they are thought to have been attached distally. Some cones are known to have been heterosporous and this was prob-

ably the rule throughout the family. It was formerly thought that both the *Lepidodendraceae* and *Sigillariaceae* became extinct with the Paleozoic but cones considered to be related to the *Lepidodendraceae* and named *Lycostrobus* are recorded from the Upper Triassic (Rhätic) of Sweden, and certain remains from the Lower Triassic (Bunter) of Europe, known as *Pleuromeia* and sometimes made the type on a separate family, are now believed to represent the *Sigillariaceae*. *Pleuromeia*, which is imperfectly known, is represented by stem casts of simple stems 9 to 10 centimeters in diameter, the surface covered with remote rhomboidal, *Clathraria*-like, leaf-scars. Basally the stem separates into four lobes suggestive of *Stigmara* or *Isoetes* and covered with rootlet scars like those of *Stigmara*. Poorly preserved terminal cones of crowded imbricated sporophylls are also known. The form of the stem and the growth separation of the leaf scars indicates secondary thickening; decorticated specimens resemble *Knorria*; and the thin central cylinder all point to a close affinity with the true *Sigillarias*. The cone genus *Poecilostachys* from the Triassic of France also indicate a third surviving type of the *Lepidodendrales*.

There remain for consideration two examples which indicate that some of the *Lepidophytes* had definitely progressed beyond heterospory to what amounts to the acquisition of the seed habit. The first of these, *Lepidocarpon*, comes from the Lower Coal Measure of England. The cone was of the *Lepidostrobus* type in all its immature details. Only a single megaspore reached maturity in each sporangium practically filling the whole cavity, and as it matured it was enclosed with a complete investment (integument or velum) which grew up from the adaxial surface of the sporophyll and open by only a narrow apical micropylar slit. At maturity the whole sporophyll with its integumented megasporangium was shed as a closed seedlike reproductive body.

The second spermatophytic *Lepidophyte* type, known as *Miadessmia* and coming from the Lower Coal Measure of England, was borne on a slender herbaceous form. Each sporophyll bore a ligule like those of the vegetative leaves and had a fringed lamina. The megasporangium was attached to the proximal adaxial face of the sporophyll and developed a single megaspore which filled its cavity, and was enclosed in an integument arising from the proximal region of the sporophyll which completely invested the megasporangium except for a circular micropylar opening at the beaklike distal apex of the sporangium. The micropyle was surrounded by numerous integumental hairs or tentacles which probably facilitated fertilization. Some megaspores are filled with prothallus. The whole sporophyll was shed at maturity. In some respects *Miadessmia* was more advanced than *Lepidocarpon* and while neither are morphologically homologous with the seeds of the other spermatophytes, they are physiologically true seeds which apparently did not evolve further along lines leading to higher plants as did the seeds of the *Pteridospermophytes*.

It cannot be said that there is any unanimity of opinion regarding the phylogenetic position of the *Lepidophyta*. Some students regard

their origin as entirely independent of the Arthrophyta while others regard them as probably distantly related to the pro-Sphenophyllum stock that represented the Arthrophyte ancestral line. At the other end of the phylum there are students (Seward, Potonié) who considered that the Araucariales and perhaps the balance of the Coniferophytes diverged from the Lepidophyte stock, while others justly doubt that the phylum had any higher issue.

The view advocated here, an opinion frequently advanced, is that the Lepidophyta represent a group of forms derived by reduction from more megaphyllous ancestors, and that the prevailing simple relationship between the sporangia and the sporophylls is due to simplification or reduction from sporangiophoric ancestors closely related to the theoretical pro-Sphenophyllum type. This view is based in part on a consideration of the paired sporangia of *Cantheliophorus* with their central sporangiophoric plates, on the ventral pad of *Spencerites*, the core of sterile tissue in *Mazocarpon*, the sterile plates in various *Lepidostrobus* sporangia and the stalked sporangia of the modern *Psilotales*. A consideration of the details of morphology and the fossil record, too extensive a subject for presentation in the present brief review, leads to the conclusion that the Lepidophytes are not related to any of the higher seed plants and never gave rise to more highly organized types.

Pteridospermophyta.—The recognition and partial elucidation of the seedferns of the Paleozoic is one of the outstanding paleobotanical achievements of the last decade. It is needless to dwell on the immense advantages which seed-bearing confers on the plants which have acquired this habit. The mere fact that seed plants are the dominant existing plants is sufficient proof of this. Over a generation ago Stur suggested that the fronds of *Neuropteris*, *Alethopteris* and others form genera of fernlike fronds exceedingly common in the Paleozoic, were probably related to the cycads since they were never found in a fruiting condition like normal ferns. Subsequently the anatomy of certain petrified stems showing a combination of fern and cycad characters led to the proposal of a group, the *Cycadofilicales*, for these intermediate types. Meanwhile the structure of a considerable number of Paleozoic seeds suggestive of cycads, ginkgos and gnetales had been described, but beyond correlating some of them with *Cordaites* little was known of the plant which bore the majority. In 1903 Oliver and Scott succeeded in proving that certain seeds (*Lagenostoma*) were borne on fronds of the *Sphenopteris* type and these in turn were attached to stems known as *Lyginodendron*. This discovery stimulated an interest in the subject and a succession of discoveries followed so that enough is now known to warrant considering a large number of the supposed Paleozoic ferns as Pteridosperms or seed ferns. The manifestly primitive characters show in one feature or another, such as the more or less free nucellus, the complex vascular supply of the seeds, their total lack of an embryo, the fact that both megasporangia and microsporangia were borne upon but slightly modified foliage leaves of decomposed fernlike fronds, and various recondite histological characters, justify regarding the seed ferns as representing a dis-

tinct phylum—the Pteridospermophyta. They were gymnospermous in habit and some students regard them as a subordinate class of gymnosperms—a taxonomic term that has outlived its usefulness for other than descriptive purposes.

The Pteridospermophyta may be tentatively characterized as plants with the habit and to a large extent the anatomical features of ferns, but differing in producing integumented megasporangia or seeds borne on the usually but slightly modified fernlike foliage and never aggregated into true strobili, having secondary thickening in both stems and roots.

From the rapidly increasing contributions to the knowledge of the Pteridosperms it will suffice to describe a few of the better known forms. Among these the best known is *Lyginodendron*, or *Lyginopteris* as it is more properly called. *Lyginopteris* represents a group of species with slender, scrambling, mostly unbranched, stems of considerable length bearing large forked decomposed fronds upward of a metre in length and long known under the name of *Sphenopteris Hæninghausi*, whose persistent petioles (*Rachiopteris*) were almost as large as the main stem on which they were arranged in a two-fifth spiral. The roots (*Kaloxylon*) were partly adventitious. The stem cortex was fibrous and reticulate and was clothed with spines and capitate glandular hairs. The seeds (*Lagenostoma*) were borne in lobate cupules, while the pollen was on the other and more reduced fronds in rosettes of six or seven fusiform bilocular sporangia (*Crossotheca*).

Lyginopteris was monostelic with a large pith containing sclerotic tissue. Primary wood of five to nine collateral strands. In all but the most immature stems there is a broad zone of secondary wood of pitted tracheids and medullary rays. The cambium was persistent and is sometimes petrified, as is the phloem. The cortex comprises a thin periderm and an inner poorly preserved soft cortex and an outer cortex characterized by radial bands of fibrous tissue. Leaftraces mesarch and double. Anomalous features are the occasional formation of inverted secondary wood by the intrusion of the cambium through a foliar gap.

The seeds, five or six millimeters in length, were borne in a lobed cupule and were orthotropous and radially symmetrical, with a single integument confluent with the nucellus except distad. The free part forms a plug and the pollen chamber was hence reduced to a conical slit. The integument was supplied by nine vascular strands which ran to the apex which formed a fluted dome or radially septate canopy at the apex of the barrel-shaped seed.

The microsporangia were found in connection with vegetable fronds and are of a type known as *Crossotheca*. Other types of microsporangia may well have been present in different species of *Lyginopteris*, as for example those called *Telangium*, in which the sporangia are crescent proximad. A second genus of seed ferns which is fairly well known is *Heterangium* which had long slender angular stems with large and graceful forked (*Sphenopteris elegans* Brongn.) fronds arranged in a three-eighths spiral. While the evidence is less conclusive than in *Lyginopteris* there are good reasons for considering the seeds known as *Sphaerostoma* as those of *Heterangium*. Hete-

rangium had a monostolic stem like *Lyginopteris* but the pith was replaced by mesarch primary wood as in some recent ferns. The secondary zone was thin. The seeds (*Sphaerostoma*) are small with an inner integument and an outer integument or cupule, both with an elaborated vascular supply. The free apical part of the nucellus is a relatively flat plinth surmounted by a central dome or lagenostome which is surrounded by an annular pollen chamber. The free apical part of the integument formed a frill or canopy with eight radial crests around the micropyle. Heterangium had a greater range than *Lyginopteris* being found from the Lower Carboniferous to the Permian. Seeds of *Lyginopteris* or Heterangium are found in the French coal measures associated with the frond genera *Sphenopteris elegans*, *S. dissecta* and *S. obtusiloba*.

A second family type to which at least four genera are referable is the *Medullosaceae*. These are characterized by the enormous development of the fronds of the *Neuropteris* and *Alethopteris* type with petioles several centimeters in diameter. This enormous display of foliage is doubtless to be correlated with the peculiarities in the anatomy of the stems. The most primitive known genus, one indicating the point of departure of the other and more specialized members of the family, is *Sutcliffia* of the English Lower Coal Measures.

Sutcliffia had a large pithless central stele of centripetally formed wood from which meristemes branch and divide and fuse irregularly and eventually give rise to leaftraces, a large number of which enter each petiole where their structure is concentric. Secondary wood is but feebly developed. The next stage in the evolution of these forms away from the Heterangium type is furnished by *Medullosa anglica* which is polystelic with normally three steles, each developing secondary wood. The stems were as much as seven or eight centimeters in diameter and bore spirally arranged decompound fronds with decurrent petioles. Many adventitious roots were formed.

Without stopping to dwell on the histological details we pass to the exceedingly complex *Medullosas* of the Permian in which the steles become very numerous and are differentiated into inner "star rings" and outer "plate rings" systems, the latter forming a peripheral zone which is an almost closed woody cylinder. Successive extrafascicular zones of wood and bast were developed in several species. The leaf traces which are at first concentric break up into strands with external protoxylem, several from different levels of origin entering each petiole. The peculiar arrangement in these later *Medullosas* is a necessary outcome of large polystelic stems with secondary thickening and appears to have constituted a rather impractical experiment in attempting to develop secondary thickening around numerous steles in a single stem. If the theory advocated by Worsdell, Chodat and others is substantiated it would appear that certain of the Permian *Medullosas* solved this problem in the mechanics of stem structure by suppressing the centripetal portions of the steles while the centrifugal and continuous portions characterized forms which passed by gradations into the *Cycadophytes*. Scott and Solmslaubach on the other hand regard the *Medullosaceae* as a highly

differentiated derivative of a Heterangium-like ancestor which became so specialized that it became extinct during the Permian.

Other genera that appear to belong to this family are *Colpoxylon*, *Rhexoxylon* and possibly *Steloxylon*, all based upon fragments of petrified stems from the Paleozoic of Europe, Africa and Asia.

Medullosa petioles are referred to the genus *Myeloxylon* and structural material has been described from both Europe and America. The foliage of *Medullosa* was of the frond types known as *Neuropteris*, *Alethopteris* and *Linopteris* all of which were exceedingly abundant and cosmopolitan in the later Paleozoic floras. Impressions from the Scotch Carboniferous show large *Rhabdocarpus* seeds attached to the fronds of *Neuropteris heterophylla* and similar but still larger seeds attached to Belgian specimens of *Neuropteris obliqua*.

The microsporangia appears to have been four valved and terminal on naked pedicels in *N. heterophylla* or marginal on orbicular or cuneate pinnules as in *Potonia*, *N. gigantea* and *N. Carpentieri*. Although no seeds have been found in actual connection with *alethopteris* there are good reasons for believing that some species at least (e.g., *A. lonchitica*, *A. serlii*) bore seeds of the *Trigonocarpus* type. The latter, which are often exceedingly common as impressions and casts, as described from petrified material are elongate-oval radially symmetrical. The testa is thick and consists of an outer flesh (sarcotesta), a shell (sclerotesta) and an inner flesh. The shell has three longitudinal ribs which characterize the seeds when preserved as casts after the decay of the outer flesh. Less prominent lines are intercalated between the main ribs. There was a long triangular micropylar canal leading to a small pollen chamber in the apex of the nucellus and the latter is free to the base.

Other genera that may represent sporangia of different types of *Medullosaceae* are *Codonotheca*, *Schützia*, *Whittleseyia*, *Dolorophyllum* and *Ottokaria* (?).

The bulk of the remaining types which are referred to the *Pteridospermophyta* are based upon anatomical studies of stem or petiole fragments ranging in age from the Devonian (*Kalymma*) to the Permian and will not be described in the present connection. In addition to these, several types of fronds formerly referred to the ferns have been proven to be seedbearing. Thus fronds referred to *Pecopteris Pluckenetii* but probably representing *P. sterseli*, had slightly reduced pinnules bearing terminal oval seeds with a thick sarcotesta giving the impressions the appearance of having narrow wings. This discovery is of special interest since typical *Pecopteris* fronds have been shown to have constituted the foliage of *Psaronius* (an undoubted fern) and they frequently show fern fructification of the *Asterotheca* or *Scoleopteris* type. A second fern, *Aneimites fertilis*, from the Appalachian Pottsville had small bilaterally symmetrical seeds on the somewhat reduced pinnules, the fleshy sarcotesta giving the impressions the appearance of having narrow wings. Other associations of seeds and fronds not found in organic union are the frond species *Eremopteris artemisifolia* and the seeds *Samaropsis acuta*,

the frond species *Aneimites bellidulus*, and the seeds *Lagenospermum Arberi*.

It has been suggested that the Gondwana genera *Glossopteris* and *Gangamopteris* were *Pteriosperms*, but there is as yet no basis for this view. The peculiar Permian frond genus of Asia and North America known as *Gigantopteris* is found in constant association in the latter country with flat cordiform alate seeds borne in the concavity of an abovate reduced pinnule with the *Gigantopteris* venation and associated with these are detached two ranked strobiloid organs consisting of similar bract like pinnules bearing small oval pendant microsporangia—not true cones but definitely more strobiloid than any demonstrated *Pteridospermophyta*.

It is evident that the *Pteridospermophyta* constituted a large and varied plexus of synthetic seed plants our knowledge of which is too imperfect to warrant an extended discussion of their phylogenetic relations. That they were descended from the ferns is obvious, but whether from the more complex *Cœnopteridæ* (e.g., *Asterochlana*) through the polystelic *Medullosacæ* or from a simple protostelic form of *Botryopteracæ* through *Lyginopteris* is debatable. They seem to show an as yet undemonstrated relationship with the Paleozoic *Marattiaceæ*. Within the phylum Scott regards them as showing two lines of descent, one through the evolution of a single stele and leading in the direction of the *Cycadophytes* and the other toward polystely which eventually became extinct. Chodat on the other hand regards *Lyginopteris* as a true fern with specialized megasporangia without higher issue, while he considers the *Medullosacæ* as the ancestors of the *Cycadophyta*.

Whatever the details of descent the *Pteridospermophyta* in some of their forms undoubtedly stand in an ancestral relationship to the *Cycadophytes* and they may well have merged in their earlier manifestations with the same stock that gave rise to the *Cordaitales* and *Ginkgoales*.

Cycadophyta.—No existing group of plants has excited more interest in recent years than the existing cycads (order *Cycadales*). Before the peculiarly organized Mesozoic forms were understood, the wealth of foliar impressions of cycad-like fronds in the Mesozoic rocks throughout the world and similar less abundant remains in the later Paleozoic, led to the conclusion that the cycad line was simply another example of an ancient, persistent, rather uniform, stock derived from the ferns, whose existing representatives were the straggling survivors of a type which attained its maximum development in the older Mesozoic. The researches of Carruthers, Solms, Laubach, Nathorst, Lignier and Wieland have shown that the group was large and diversified and includes at least two extinct orders very different from the existing cycads; that its origin is to be looked for among the seed ferns rather than the true ferns; and that existing cycads represent relatively modern and never very abundant derivatives of this ancient stock.

In sketching the morphology of the *Cycadophytes* the reader has to bear in mind that we are dealing with an extensive group that appeared in the record as early as the Carboniferous (Westphalian) and continued to the present, and that aside from the recent forms and a few

exceptional fossil forms like the Rhatic *Wielandiella* and the Lower Cretaceous *Cycadeoids* and *Williamsonias*, we have only the remains of foliage as a clue to relationships and practically no information regarding anatomy or fructifications; the latter we infer from the analogy of known forms were highly variable. As sketched in the following paragraphs the *Cycadophyta* are somewhat arbitrarily segregated into three subordinate groups—the aberrant *Cycadeoidales*, which are not as far removed from the second group, the Mesozoic and existing *Cycadales*. The third group, for which the inappropriate name *Williamsoniales* is retained, includes the balance of the *Cycadophytes*. It is not a compact group and the progress of discovery will doubtless show it to be unnatural. In its beginnings it approximates the *Pteridospermophyta* and also shows points of possible contact with the *Gnetales* and *Ginkgoales*. In its more evolved members (e.g., *Williamsonia*) it approximates the *Cycadeoids* to such an extent that Wieland and other authorities group the former and the latter together. The two points of view are entirely in agreement regarding the facts and differ merely in the placing of the boundary between the two groups—a not very serious difference in an evolving series of forms.

The *Cycadeoidales* appear to represent an evolution from the older *Williamsoniales* stock and according to our present knowledge they are confined to the Jurassic and Lower Cretaceous. Their prevailingly tuberous trunks are individually abundant in a silicified condition in certain sandy strata of those ages, particularly in the Portland Dirt Bed of the Isle of Wight, the Patuxent formation of Maryland and the Morrison beds of the Freezeout Hills in Wyoming. By far the largest number have been found in the similar strata of the Dakota formation, which outcrops in the Black Hills rim. Similar remains in less abundance have been found in France, Italy, Galicia and elsewhere. Their wonderful preservation and exceptional morphological features have resulted in unusually painstaking researches which have shown that the group as a whole was one of rather limited variation and stereotyped organization, relatively no more abundant in Jurassic and Lower Cretaceous time than are the *Cycads* in existing floras. The salient features briefly enumerated are a tuberous or short columnar stem, sometimes an aggregate of tuberous stems, as in some species of *Encephalartos*. The stem was encased in a heavy armor of persistent leaf bases, which largely obviated the necessity for the development of a thick zone of mechanical woody tissue in the stem. The interstices of leaf bases were filled with multicellular scales (unicellular hairs in the Liassic *C. Micromyela* Morière) corresponding to the ramentum of ferns, in some cases (as in the genus *Cycadella*) very long and enclosing the whole trunk in a felt-like mass. This ramental covering appears to have facilitated their subsequent silicification, so that normally the fossil trunks show the ramental areas as prominent partitions, separating the subrhombic angular cavities left by the leaf stalks which had decayed or were shed before fossilization. Among the leaf bases occur numerous short axillary branches each terminated by a solitary fructification or flower. The anatomy of the stem is much like that of

the cycads. There is a thick cortex, a comparatively thin vascular cylinder and a very large pith containing secretory sacs rather than gum canals. The vascular bundles are collateral, the protoxylem is next the pith (endarch) and the few spiral marked tracheids are soon replaced by scalariform tracheids which appear to characterize the phylum, although pitted tracheids are recorded in *Cycadeoidea micro-myela*. In the leaves, however, the structure is mesarch, suggesting their pteridophytic ancestry. The leaf traces are single and direct and thus more simple in their arrangement than in existing cycads.

The axillary branches bear reduced leaves or bracts spirally arranged and are of a length to bring the terminal flower at about the general level formed by the persistent leaf bases. The branch axis expands into a subhemispherical or conical receptacle. At its base and immediately beyond the enclosing bracts was inserted a whorl of compound microsporophylls, united into a continuous sheath proximad, expanding distad into a bipinnate frond with alternate pinnae, all of which, except the apical and basal pairs, bearing two rows of syngangia, suggesting those of a marattiaceous fern, the whole greatly resembling a fertile fern frond rather than a verticil of stamens, and like the former circinate in vernation. The surface of the receptacle above the staminate collar is beset with slender pedicels each bearing at its extremity a single orthotropous seed, the interspaces packed with sterile appendages known as interseminal scales, which expand apically so that only the micropylar part of the seed reaches the surface and the whole is compact and simulates a closed pericarp. The whole fruit-like body is ovoid or turbinate in shape, several centimeters in length, the surface a mosaic of the expanded tips of the interseminal scales, between which the micropylar tubes of the seeds protrude. The microsporophylls are only preserved in immature strobili. They have disappeared at a later period but their former presence can usually be inferred from the basal shoulder that marks their insertion on the receptacle. The probabilities are that all the cycadeoids were bisporangiate, although this is disputed in the case of some species. The seeds are very small as compared with those of living cycads and have a two or three layered testa, prolonged upward into a micropylar tube the outer palisade layer of which at the shoulder where it joins the seed being expanded by radical extensions forming five or six radial wings. The cavity of the seed is completely filled by a large dicotyledonous embryo which in its developments, unlike any living gymnosperms, destroys all of the endosperm.

A variety of cycadfronds are found in the deposits which have yielded the petrified trunks, but our information regarding their actual foliage is furnished by small unexpanded petrified material which show pinnate fronds of the *Zamia* type, circinate in venation with erect pinnules. It seems probable from the large number of cones in the same stage of development in some trunks and their complete absence in other large trunks, that seed formation was the culminating event of many seasons of vegetational activity, possibly occurring but once at the maturity of the plant, but more probably repeated at increasing intervals throughout life.

Fronds indistinguishable from those of cycadeoids are cosmopolitan from the Triassic to the Upper Cretaceous, but there is no means for determining to what an extent they belong to the cycadeoids and the probabilities are strongly in favor of considering most of them as the fronds of the order that I have termed the Williamsoniales. The Williamsoniales comprise a much more protean and long-lived group of forms, unfortunately known almost entirely from impressions. They appear in the later Paleozoic in the genera *Plagiozamites*, *Pterophyllum* and *Sphenozamites*, are very prominent in the Triassic, Jurassic and Lower Cretaceous and are still present but in reduced numbers in the Upper Cretaceous after the cycadeoids had become extinct. The nature of their remains precludes a concise summary of their features. Both the very abundant foliar remains as well as such fructifications as have been preserved indicate a much wider variability than among the other two orders of cycadophytes. The sole feature that at present can be considered as probably characteristic of the order is the relative slenderness and elongation of the stem and the frequency with which it branched, often dichotomously. It is not possible to consider the various foliar types in the limits of the present paper, a subject requiring much study and never adequately discussed and only a few of the more representative types will be mentioned. Among these one of the most remarkable is the genus *Wielandiella* from the Rhaetic of Sweden. *Wielandiella* had an elongated slender stem not over two centimeters in diameter, with repeated dichotomies, prevailingly naked except in the region of the forks where it bore spirally arranged rather reduced fronds of the *Nilssonia* or *Anomozamites* type. In each fork was a subsessile fructification surrounded by bracts. These fructifications are met with in two forms, probably representing different ages and states of preservation. In the one it consists of a small pyriform axis separated from the peduncle by a swollen striated collar bearing oval microspores on the surface of greatly reduced scale-like sporophylls. Ovulate structures on the pyriform axis appear to have been vestigial. In the second type the axis is hidden by the linear bracts but its surface reveals a regular pattern of interseminal scales between which the micropylar tubes project, indicating an ovulate organization like that of the cycadeoids and Williamsonia.

Another old genus is the Rhaetic genus *Cycadocephalus*, also from Sweden and based on impressions of a large fructification 10 centimeters long and seven centimeters in diameter. The peduncle is slender and shows no leaf or bract scars. No trace of a central ovulate receptacle is discernible, the head consisting of a cluster of linear microsporophylls with a keel-like midrib on their inner faces and bearing on either side of this midrib linear pointed syngangia.

A third Rhaetic genus is *Weltrichia* from Franconia, based upon a funicular fructification, the cup of which was formed by the concrescent bases of about a score of broadly linear microsporophylls, the whole 10 centimeters in length and nine centimeters in diameter. The free lanceolate apical portions of these bear linear appendages five to eight millimeters long

attached to their inner faces, comparable with the synangia of Cycadocephalus. No traces of ovulate structures are known, so it cannot be determined whether either Cycadocephalus or Weltrichia were unisexual or bisexual.

As previously mentioned, a variety of frond genera of late Triassic, Jurassic and Lower Cretaceous ages are found from Japan and New Zealand on the east to California and Alaska on the west, and from Franz Josef Land, Spitzbergen and Greenland on the north to Graham Land on the south. No continent is without an abundant representation. Associated with these frond genera at many localities, particularly in India, England and southern Mexico, are the objects commonly referred to the genus *Williamsonia*.

The most celebrated of these is perhaps *Williamsonia gigas*, discovered early in the last century in the Jurassic outcrops along the Yorkshire coast, and the basis for Williamson's historic restoration. These have been found in organic union with foliage and stems. The stems (*Bucklandia*) were slender, five centimeters in diameter, covered with rhomboidal leaf scars, with a crown of Zami-like fronds about two feet long, and bearing at the summit slender peduncles 20 to 30 centimeters long, covered with spirally arranged scale leaves and terminated with an ovulate receptacle bearing pedicellate seeds similar to those of Cycadeoidea, surrounded by bracts or sterile sporophylls united proximad to form a disc or cup. No trace of microsporophylls are certainly known in this species, although the probabilities are that it was bisporangiate, in fact certain staminate discs have been referred to this species by various students.

Naturally a very large number of different species of *Williamsonia* have been described from a variety of Mesozoic horizons and localities, but few of these show essential features or have been exhaustively investigated. A very characteristic form (*W. virginiensis*) occurs in the Lower Cretaceous of Virginia and another in the Upper Cretaceous of Delaware.

Among the better known forms are *W. spectabilis*, from the Yorkshire Jurassic, which shows a funicular disc prolonged into linear lanceolate microsporophylls bearing on their inner faces fertile pinnæ carrying reniform synangia. A central ovulate receptacle is wanting. *W. whitbiensis*, also from the Yorkshire Jurassic, is similar to the preceding, but the fertile pinnæ are reduced and the reniform synangia are borne on either side of the midrib along the inner face of the free part of the microsporophylls.

Still another type is *W. mexicana*, from the Lias of Southern Mexico, in which the cup is deeply campanulate with 10 short, narrow, free lobes bearing two rows of lateral synangia.

The only petrified *Williamsonia* known is the imperfectly preserved *W. Scotica*, from the Jurassic of Scotland, which shows hairy bracts, no traces of microsporophylls and a central receptacle consisting of interseminal scales and pedicellate seeds exactly similar to Cycadeoidea.

An interesting and more reduced type, whose affinities indicate the survival to the middle Jurassic of the *Wielandiella* type, is one made the basis of the genus *Williamsoniella*. If the various parts are correctly correlated

they show slender frequently dichotomous stems bearing scattered leaf scars and believed to have borne the associated type of foliage known as *Taeniopteris vittata*. In the stem forks are pedunculate bracteate fructifications consisting of a whorl of cuneate microsporophylls, bearing five to six sessile reniform synangia on either side of the inner keel. Within the whorl of microsporophylls a pyriform receptacle with a sterile crown is covered with small interseminal scales and short stalked seeds like those of *Williamsonia* and *Cycadeoidea*.

Remarkably well-preserved fronds from Greenland and elsewhere described as *Cycadites* have recently been shown to possess a double midrib separated by a stomatal groove, and these forms have consequently been made the basis for a new genus, *Pseudocycas*, although nothing is known of the plants which bore these anomalous fronds.

A frond genus that deserves mention is *Podozamites* to which a very large number of often detached pinnules have been referred, some of which are with difficulty distinguished from the coniferophyte genera *Nageiopsis*, *Araucaria*, etc. These are widespread and more or less abundant from the Triassic to the Upper Cretaceous. In the more perfect specimens *Podozamites* shows a slender rachis with somewhat irregularly spaced parallel veined lanceolate pinnules, often deciduous. *Podozamites* may well be composite. In certain species the pinnules appear to be borne on definite short shoots, and the associated fructifications (*Cycadocarpidium*) consist of loose cones of sporophylls much like the vegetative leaves and bearing proximad ovules with pointed wing-like appendages. *Podozamites* in some of its forms may thus constitute a point of contact between the cycadophytes and coniferophytes or it may really belong with the latter phylum and have no cycadean relationship.

The Cycadales have tuberous or columnar, sometimes subterranean, sparingly or not at all branched, stems, covered with persistent leaf bases, bearing a crown of large compound leaves and apparently terminal dioecious strobilæ (truly lateral). The cortex is thick, the vascular cylinder thin and the pith large. Bundles are collateral and endarch in the stem, but often misarch and even concentric in the leaf traces and strobilar axes. The leaf traces girdle the stem, entering leaves on the opposite side from which they separate from the vascular cylinder.

The existing cycads constitute a rather compact group of nine genera and about 110 species indigenous in the warmer regions of both hemispheres — *Cycas*, with some 16 Oriental species, and *Zamia* with about 30 occidental species being the dominant genera. Besides *Zamia* the genera *Microcycas*, *Dion* and *Ceratozamia* are American; *Encephalartos* and *Stangeria* are African, while *Cycas*, *Macrozamia* and *Bowenia* are Asiatic or Australian. In individual abundance they do not play a leading rôle in any forest assemblage, although the small *Stangeria paradoxa* forms thickets in south-eastern Africa and *Macrozamia spiralis* forms a scrub over considerable areas in eastern Australia. For trunk-forming plants they are inconspicuous and vary from the dwarf *Zamias*

with underground stems or epiphytic forms to some of the species of *Cycas* which reach a height of 20 metres and live to a great age.

The Cycadales and presumably the majority of the fossil cycadophytes send down a primary root which continues as a tap root, often approaching the trunk in size. All the forms have compound leaves. The leaves are in whorls crowning the stem or the branches in branched forms, giving a strikingly handsome appearance. Each whorl alternates with a whorl of scale leaves. The whorl may consist of but a few to over 100 fronds, varying in size from a length of 10 centimeters to more than three meters, and the fronds may have but a few to as many as 250 pinnules. The structure is xerophytic and the pinnules generally have entire margins. They vary from lanceolate to linear and acicular. In some *Zamia* and *Stangeria* the margins are serrate. In *Dion* they are thorny and in *Encephalartos* they are inequilaterally lacerate.

A feature reminiscent of ancient habits and shared only by *Ginkgo* among existing seed plants is the fertilization of the egg cells by multiciliated swimming sperm cells.

The histological and morphological details of the Cycadales belong to modern rather than paleobotany and need not be dwelt upon in this connection.

Both the staminate and ovulate sporophylls are always aggregated in strobili, which are compact and rather uniform throughout the order, except that in *Cycas* the ovulate strobilus instead of being compacted in a cone consists of rosettes of sporophylls resembling reduced foliage leaves in which ovules replace the lower pinnæ or teeth.

The fossil record of the Cycadales is extremely meagre. It includes certain not conclusively determined ovulate cones from the Keuper of Switzerland, resembling those of *Zamia*; and more convincing carpellary leaves, like those of the modern *Cycas*, from the top of the French Triassic (*Cycadospadix hennoquei*), from the Kimeridgian of Italy and Scotland (*Cycadospadix pasianianus*) and from the Rhaetic of Sweden (*Cycadospadix integer*), which demonstrate the presence of true Cycadales in the late Triassic and Jurassic. The Cretaceous records are few and not especially trustworthy. During the Tertiary a few undoubted remains of cycads occur at scattered localities, demonstrating a more extended geographical range than obtains at present. Thus there are two species of *Zamia* in the lower Eocene along the shores of the Mississippi embayment. A third species occurs in the basal Eocene of Belgium and a fourth in the late Oligocene or lower Miocene of Chile. Oligocene species include a *Zamia* from France, an *Encephalartos* from Greece and a not certainly identified *Ceratozamia* from northern Italy. The Miocene records include a *Zamites* and a *Cycadites* from Switzerland.

Coniferophyta.—The Coniferophyta corresponds almost exactly to the Gymnospermæ of the older students. Their outstanding characteristic is the exposed ovules discovered by Robert Brown in 1827. This feature has ceased to be diagnostic since it is common to the Pteridospermophyta and Cycadophyta, and is evidently of ancient lineage. Although probably more continuously and abundantly repre-

sented in the geological record than any other group of plants, it cannot be said that our knowledge of either the comparative morphology or the geological history of the phylum warrants a dogmatic view of their phylogeny.

All the known coniferophytes are woody plants with pronounced secondary growth; nearly all are trees and it is extremely doubtful if the group ever contained herbaceous forms. They show rather uniform xerophytic structure, due possibly to the character of the water-conducting tissues or to the evergreen foliage, since of the existing species only the bald cypress, ginkgo, the larch and *Glyptostrobus* are deciduous. They usually cannot compete successfully with angiosperms under genial conditions. Structurally the bundles are collateral and a primary persistent cambium develops all of the secondary tissues. The water-conducting tissues are tracheids with bordered pits, and true vessels are found only in the Gnetales. Both mega and microspores are normally formed in cones (strobili), which are never bisporangiate.

The Araucariales and Taxales are dioecious while the Coniferales, Cordaitales and Ginkgoales are monœcious. The sporophylls follow the leaf arrangement and are hence spiral or cyclic. The staminate cones have two or more sporangia to the sporophyll, hence these are less numerous than in the Cycadophytes. They are exceedingly variable and very characteristic for genera. The ovulate cones are varied and their morphological interpretation has been warmly debated for a century. A digest of the various opinions advanced is given by Worsdell (*Annals of Botany*, Vol. 18, p. 57, 1904). Pollination is effected through the agency of the wind (anemophily). The stock is of great antiquity and contemporaneous groups are to be regarded as divergent or convergent and not directly filiated. It has been demonstrated beyond reasonable doubt that the Cordaitales, Ginkgoales and Cycadophytes are alike related to the Pteridosperms and Ferns. In the case of the Coniferales and Araucariales this is not so certain and some students (Renault, Campbell, Potonié, Seward) consider the later groups as of Lepidophytic origin. The most interesting order from an evolutionary standpoint—the Gnetales—since they seem to form a connecting link with the amentiferous Dicotyledonæ have an ancestry completely unknown, although they show certain structural and developmental points of contact with the Cordaitales, Ginkgoes and Cycadophytes.

In the present treatment the coniferophytes are grouped in six orders—Cordaitales, Ginkgoales, Taxales, Araucariales, Coniferales (Pinales) and Gnetales which are best discussed separately. The oldest of these orders, long since extinct, is the Cordaitales. The Cordaitales were exceedingly abundant and presumably varied at several horizons in the Paleozoic, and the synthesis of a study of impressions of their foliage and fructification, pith casts and petrifications enables us to draw a satisfactory picture of their general appearance and habit, although as yet it is usually impossible to correlate specific foliar impressions with petrified stems and seeds. They were tall and relatively slender trees with trunks that were frequently over 100 feet in height and unbranched except at the crown where their spirally arranged foliage of simple and often

large parallel veined leaves were displayed. Lafform has been used as a basis for the three forms genera—*Eucordaites*, with spatulate blunt tipped leaves often several inches in width and two or three feet in length; *Dorycordaites*, with pointed leaves approaching those of *Eucordaites* in size; and *Poacordaites*, with narrow linear leaves. The parallel veined leaves unbranched in *Poacordaites* but repeatedly forked in *Dory-* and *Eucordaites* resemble those of corn and the early writers consequently considered *Cordaite*s as a monocotyledon.

The stem has the general features of a modern conifer except for the much larger pith which was often discoidal as a consequence of the rapid elongation of the stem, so that casts yield characteristic forms described by the early writers as *Artisia* or *Sternbergia*. Structurally, the wood, commonly known as *Araucarioxylon* or *Dadoxylon*, was centrifugal with the narrow spiral protoxylem lying at the periphery of the pith, succeeded radially by spiral tracheids soon passing into scalariform elements which after an interval pass into pitted tracheids greatly resembling those of the modern *Araucariaceae*. The bordered pits, limited to the radial walls of the tracheids, usually in two or more rows and so densely crowded in alternating series that they tend to be hexagonal in outline. The rays were narrow, originally they may be three cells wide but those of the secondary wood are usually one or at the most two cells wide. The phloem, of sieve tubes, parenchyma and some bast fibres, was like that of modern conifers. The leaf traces were often double as in some *Pteridosperms* and *Ginkgo*. The bark was thick but is usually not well preserved. The roots were feebly developed for such large trees, diarch in structure with a broad zone of secondary wood, conforming histologically with that of the stem. The leaf structure is comparable to that of a cycad pinnule with collateral bundles and the stomata were confined to the lower surface.

The fructification shows considerable variation. The catkins, as commonly preserved as impressions under the name of *Cordaianthus* show an elongated axis with bracteate pedicels bearing the alate bilaterally symmetrical cordate seeds. Petrified material shows the staminate catkins to consist of a thick axis bearing spirally arranged bracts between which the microsporophylls were inserted, either singly or massed near the apex. Each microsporophyll consists of a pedicel surmounted by three or four or more vertically elongated pollen sacs which split longitudinally, and contain large pollen grains which often show a group of prothallial cells. In appearance the ovulate cones are much like the staminate. The axis is thick and clothed with spirally arranged bracts many of which are sterile. In the axis of others are found short stalked ovules with bracteoles. The ovules had two integuments—an outer fleshy one and an inner one which became crustaceous. The ovule shows a nucellus with a large pollen chamber and a beak like micropylar canal. The pollen grains found in the canal and pollen chamber are larger than those in the pollen sacs with their mass of prothallial or antheridial cells more extensively developed and it is hence inferred that the

habit of forming pollen tubes had not yet been developed and motile sperms were formed directly.

The seeds of numerous species are common as impressions and have frequently been found in a petrified condition. They exhibit considerable variation in size and form and commonly go under the name of *Cordaicarpus*.

Several additional types of Cordaitan wood anatomy are known. These include *Mesoxylon* of which several species have been described from the English Carboniferous, which help bridge the gap between *Cordaite*s and the family *Poroxyloaceae* of the Carboniferous and Permian. Both *Mesoxylon* and *Poroxylo* develop centripetal xylem in the primary wood. A third family the *Pityeae*, based on large trunks from the Lower Carboniferous of Scotland, is chiefly distinguished by the wide rays. Other anatomical genera in the Cordaitan plexus include *Callixylon* of the Upper Devonian of Europe and America, *Caenoxylon* of the Russian Permian, *Mesopitys* of the Permian, *Parapitys* of the Middle Carboniferous and *Archaeopitys* of the Lower Carboniferous of Kentucky. Evidently much remains to be learned before these and other as yet unknown Cordaitan forms can be properly allocated. The *Cordaite*s show clearly their origin from the same ancient plexus that gave rise to the *Pteridosperms*. They likewise show points of contact with the later coniferophyte orders especially with the *Ginkgoales*, *Taxales* and *Araucariales*.

Ginkgoales.—The *Ginkgoales* as a group can be characterized only by the features of the single existing species and these may be misleading when applied to remote ancestral forms. This obvious conclusion must be borne in mind in the attempts to relate these forms to the ancient *Cordaite*s on the one hand and the modern *Abietineae* on the other. Thus the formation of pits on the tangential walls of the tracheids at the end of the annual ring is a purely physiological response to an alternation of growth and resting periods and is due to climatic changes, as is the deciduous habit, and it is very probable that neither of these characters was present in early Mesozoic forms or has any phylogenetic significance. Similarly the paired sporangia appear to represent a reduction from the more numerous sporangia of the Mesozoic species.

The modern *Ginkgo* has a persistent primary cambium, collateral bundles, double leaf trace, no wood parenchyma, resin ducts in both pith and portex, tracheids with radial opposite pits separated by so-called bars of Sanio. The leaves are comparable anatomically with those of cycads but are simple and deciduous. They are borne on either long terminal shoots or in tufts at the apex of short auxiliary shoots—the latter habit shared by some fossil species of *Baiera*. The pollen is slightly winged and is formed in microsporangia which are normally in pairs, pendant from the expanded tips of sporophylls arranged in loose catkins in the axils of scale leaves at the end of short shoots. The megasporangia are also normally in pairs, although but one ovule matures, and are at the end of a long stalk which is morphologically a shoot and in some Mesozoic species bore more than two ovules. The sperms are ciliated and free swimming as in the *Cycadophytes* and

Pteridophytes. *Ginkgo* was formerly considered a member of the family Taxaceae although its resemblance to cycads has long been known. It appears to have been derived from the Paleozoic plexus of Pteridospermophyta, and shows points of contact with both the Paleozoic Cordaitales and the Mesozoic Williamsoniales. All three groups probably had similar ancestors, but there is no evidence that the Ginkgoales have been ancestral to any existing group of Coniferales. The modern *Ginkgo* is the most isolated as well as the oldest existing arborescent form, its stock being represented in the fossil record continuously from the Permian to the present. The leaves are so characteristic that there is little uncertainty regarding their determination, although some of the older forms referred to the Ginkgoales, simulate such digitate fern fronds as *Schizaea*, and some of these are of questionable identity. The limited space forbids more than a mention of the extinct genera that have been referred to this order and which in some cases do and in other cases do not belong to this stock. Some of these genera are *Ginkgoophyllum*, *Saportaea*, *Trichopitys*, *Dicranophyllum*, *Rhipidopsis*, *Whittleseyia*, *Psymphyllum*, *Gomphostrobus*, *Trichophyllum*, *Faidenia*, *Phœnicopsis* and *Czekanowskia*. Some of these such as *Saportaea* and *Rhipidopsis* seem clearly to represent early variants of the *Ginkgo* type but the two fossil genera that stand out beyond all question are *Ginkgo* itself and the allied genus *Baiera*—the latter segregated on account of the short petiole and the repeated dichotomy of the leaf blades to form narrow elongate ultimate segments in which the veins no longer fork. The modern *Ginkgo* sometimes furnishes instances of more than the usual number of pollen sacs and ovules, and its leaves also frequently become divided to simulate those of *Baiera*. Both *Baiera* and *Ginkgo* appear at least as far back as the Permian and become abundant and varied throughout the Triassic, Jurassic and Lower Cretaceous, where frequently the seeds, immature fruits and the pollen bearing catkins, as well as the leaves, are found fossil. *Baiera* attains its maximum range somewhat earlier than *Ginkgo*, and its distribution appears to have extended beyond the known range of *Ginkgo* in South America, South Africa and New Zealand. It is evidently a waning type during the Upper Cretaceous and becomes entirely extinct before the close of that period. *Ginkgo*, on the other hand, has been found in the Tertiary of Greenland, North America, Europe and Asia, the characteristic *Ginkgo adiantoides* being abundant and scarcely distinguishable from the still existing species. The latter, long thought to be extinct except as preserved by cultivation in the temple gardens of China and Japan, has recently been reported in a wild state in western China.

Gnetales.—This order includes but three existing genera which differ widely in habit, habitat, anatomy, gametophytic structures and in endosperm and embryo formation, and yet having a thread of common characters denoting their community of origin. *Ephedra*, with about 30 species of low straggling shrubs with jointed ribbed stems and reduced leaves, inhabits the more arid parts of both the Eastern and Western hemispheres. It is the least specialized of the three genera and more like the Conif-

erales. *Gnetum*, with about 26 species of both the Eastern and Western tropics, comprises small trees or woody lianas with opposite, netted veined, dicotyledonous-like leaves, and is most advanced in the direction of the angiosperms. The third genus *Tumboa* (*Welwitschia*) is a remarkable monotypic form of western South Africa with a shortened swollen axis and but two, excessively long, parallel veined leaves, and is obviously most specialized (aberrant). All of these modern forms are evidently the end products of an ancient and diversified group which unfortunately has not been certainly recognized in the older fossil floras—*Gnetopsis* of the Carboniferous (Stephanian) of Europe and North America being, according to Oliver and Salisbury, a pteridosperm related to *Corostoma*. *Gnetum* has been definitely recognized in the Pliocene of Holland while several species of *Ephedrites* have been recorded from the Jurassic, Cretaceous and Tertiary. The relationship of these latter cannot, however, be regarded as established beyond suspicion. Leaves suggestive of *Gnetum* are also present in the Lower Cretaceous of Virginia.

The point of chief interest in the Gnetales is their angiospermous characters shown in their possession of true vessels (absent in all other gymnosperms, in their broad rays, the presence of companion cells in the bast, the incipient perianth of the inflorescence, the floral morphology, the details of sporogenesis, fertilization and embryogeny with the elimination of archegonia, the organization of eggs and the dicotyledonous embryos). Such of these features as were known to the older morphologists suggested that the Gnetales were to be looked upon as representing the progenitors of the flowering plants and this view, which has long been in dispute, has recently come into prominence again and is supported by a considerable body of evidence. Lang and Thompson have shown that the Gnetales are undoubtedly related to the rest of the gymnosperms and are not to be considered true angiosperms, as Lige advocated. On the other hand the attempt to consider them as a reduction series from the Mesozoic Cycadeoidales must be considered an abortive speculation. Some light on their geological history is greatly to be desired since the most recent work with the existing forms indicates an ancient and collateral relationship with the balance of the Coniferophyta going back possibly to the same pteridosperm plexus from which the Cordaitales took their origin. Hence comparisons of the gnetalean flower with the fructifications of existing conifers is obviously futile. In the other direction the least aberrant genus, *Gnetum*, while in no sense a "missing link," furnishes good grounds for considering an as yet unknown group of gnetalean forms as the ancestors of the angiosperms through the primitive amentiferous families.

Taxales.—The Taxales are dioecious and they differ from all other Coniferophytes except the Ginkgoales and Gnetales in that true cones are not organized, the ovules developing into seeds with a partially fleshy testa (aril) or cupule. Normally only a single ovule of the sporophyll reaches maturity in the modern forms although more seem to have been developed in extinct genera like *Palissya*.

The Taxales contain but eight of the 36 ex-

isting genera of the Coniferophytes and only about 75 of the 325 existing species. At least two and probably three lines of descent are obvious. The first of these is the stock of the family Taxaceae, which is regarded as primitive and a probable offshoot of the Cordaitales by some students, and is considered a modern reduction series by others. Whatever the intricacies of morphological legerdemain it can be positively affirmed that the Taxaceae go back at least as far as the late Triassic and are hence more ancient than the ancestors assigned for them by nonpaleobotanical students. Moreover the disconnected geographical distribution of the 17 existing species is a conclusive indication of an extended geological history, as is the greater geographical range of all of the genera in the past than they attain at the present time. The fossil record, in addition to occasional species of *Taxus* (*Taxites*) and *Tumion* (*Torreya*) from the Cretaceous to the present, includes the Triassic genus *Palaeotaxus*, the Lower Cretaceous genus *Cephalotaxites*, the Upper Cretaceous genus *Cephalotaxites*, *Cephalotaxospermum*, *Vesquia*, *Taxo-torreya*, etc. *Cephalotaxus* fruits have been found in the Pliocene of Europe and all of the other existing genera appear to have been well represented during Cenezoic times.

That the resemblance of *Cephalotaxus* to *Ginkgo* and of *Taxus* to *Cordaitanthus*, the complex vascular anatomy of the seeds, the absence of resin canals, are not illusory features of the existing species is indicated by the foregoing brief survey of the fossil forms. The second line of descent in the Taxales is represented by the family Podocarpaceae often made to include two subfamilies, the Podocarpeae and the Phyllocladoideae, while some students consider the latter to represent a third evolutionary line.

The Podocarpaceae are to-day almost as distinctively characteristic of the Southern Hemisphere as the Taxaceae are of the Northern. They comprise over 50 of the 72 existing species of the order. *Podocarpus* is easily the dominant genus with over two score existing species and is found in all the southern continents, where they form extensive stands comparable to those of *Pinus* in the North Temperate zone.

The Phyllocladoideae are to-day confined to the Australian-New Zealand region, but both subfamilies have an extended geological history. Probably their oldest authentic representative is *Palissya* (*Elatocladus*) of the Triassic and Jurassic which had dimorphic foliage and remarkable lax cones made up of flat lanceolate foliar like sporophylls with two rows of small seeds in cupules on their upper (ventral) surface. *Palissya*, to which 10 or 12 species have been referred, is abundantly represented by sterile twigs in the older Mesozoic of Europe, Asia and America, as well as in the Arctic and Antarctic regions.

Another equally old genus, of great interest but not completely known, is *Stachytaxus* which has two or three species in the Rhaetic of Sweden and Greenland. It had yewlike leaves and loose cones, each sporophyll of which bore a pair of large seeds on their upper (ventral) face, which are compared by their discoverer (Nathorst) with the modern *Dacrydium*. *Podocarpus* itself contains about a score of fossil species which appear to have been abundant and

rather widespread during the Tertiary and are doubtfully recognized in the Upper Cretaceous. The allied genus *Nageiopsis*, represented in the modern flora by the *Nageia* section of *Podocarpus* with about a dozen broad leaved species ranging from Japan to the East Indies and New Caledonia, is exceedingly abundant in the Lower Cretaceous of North America and is represented in the English Wealden and the Asiatic Neocomian. It has also been recorded from the English Jurassic and the Mesozoic of New Zealand. *Phyllocladus* occurs throughout the Tertiary of Australia and various supposedly related genera such as *Phyllocladites* of Spitzbergen and *Protophyllocladus* of North America and Asia are present in the Upper Cretaceous. Wood known as *Phyllocladoxylon* has been described from strata as old as the Jurassic.

The difficulty of correctly determining foliar specimens and the lack of structural fossil material of this order leaves much to be desired in the knowledge of the geological history of the order, but such information as is available cannot safely be ignored by weavers of phylogenetic hypotheses.

Araucariales.—The ordinal rank of the Araucariales, first clearly emphasized by Seward and Ford, receives abundant confirmation from a consideration of their organization and geological history. The difficulties of homologizing their morphology with that of the Coniferales or Taxales has led to endless discussion and to the hypothesis, previously mentioned, of regarding them as independently derived from Lepidophytic ancestors. The existing forms, about 15 in number, are segregated into the large-leaved genus *Dammara* (*Agathis*) with four or five species of the East Indian—New Zealand region, and *Araucaria* with 10 or 12 species of South America and the Oriental region. They are dioecious and form large and complex cones in which the morphological distinction of leaf and bract is eliminated. The ovules are solitary and the pollen sacs are free and pendulous. Features of the vascular anatomy made much of by morphological speculators are the persistent leaf traces, the absence of resin canals, bars of Sanio, and wood parenchyma. The tracheids are characterized by crowded alternating and often flattened bordered pits, indistinguishable from those of the Cordaitales. Foliage leaves only are present, there being no traces of the scale leaves so characteristic of the Coniferales. The existence of a variety of Mesozoic genera which combine some of the features of Araucarian vascular anatomy with Abietinaceous characters and the cone and foliar habits of a variety of genera (*Widdringtonites*, *Brachyphyllum*, *Raritanian*, *Thuites*, *Androvettia*, *Araucariopitys*, *Woodworthia*, etc.) has led some students to regard the Araucariales as derived by reduction from the Abietiniaceae, which are usually considered the most modern and specialized coniferophytes. This ingenious hypothesis entirely ignores the geological record, and the cone and foliar habits of the forms, here regarded as the more significant.

For a more exhaustive discussion of this order, see article **ARAUCAIALES**, as only a summary of the geological history of the order will be given in the following paragraphs. Petrified wood from the Paleozoic cannot be accepted as an indication of the presence of this order since

the wood anatomy is practically indistinguishable from that of the Cordaitales, hence the term *Araucarioxylon* may be of dual significance. The Upper Carboniferous and Permian genus *Walchia* had foliage like that of the modern acicular leafed *Araucaria*, bossed pith casts caused by the interlaced sclerenchyma fibres at the periphery of the pith, spirally arranged leaf cushions, Araucarian wood anatomy and single seeded cone scales, and is commonly regarded as an early member of this order, as is also the Carboniferous genus *Schizodendron* (Tylo-dendron), and the Permian genera *Gomphostrobus* and *Ulmannia*. Permian leafy twigs have been referred to the genus *Araucarites* and various older Mesozoic genera such as *Albertia* and *Pagiophyllum* probably belong in this alliance. Undoubted Araucarian wood and single seed cone scales are cosmopolitan during the Jurassic and continue unabated throughout the Lower and Upper Cretaceous. *Dammara* foliage and conescales likewise become cosmopolitan during the Upper Cretaceous, and extinct genera such as *Pseudoaraucaria*, with two-seeded sporophylls, and *Protodammara*, with three-seeded sporophylls, have also been described. The order appears to have continued its worldwide range well into the Tertiary for unquestionable Araucarian remains of this age have been recorded from the New Siberian islands north of Asia, North and South America, Europe, the East Indies, on the border of Antarctica. Africa then as now is without records. That the Araucariales began to dwindle in the late Tertiary and during the Pleistocene is shown by their absence at those times through the northern hemisphere, their presence on Kerguelen Island and in the Pleistocene of the Falkland Islands and their subfossil occurrence beyond the present range of the existing species.

Coniferales.—The Coniferales as here understood is an order coterminous with the family Pinaceæ of the older botanists and would possibly be more appropriately termed the Pinales. The details of structure and distribution belong more properly to recent botany (see article CONIFERALES), and such as are mentioned in the present connection will be introduced in the brief sketch of the three families into which the order is segregated. These are the Taxodiaceæ, Cupressaceæ and Abietineaceæ.

The family Taxodiaceæ comprises eight existing genera and about 13 existing species characterized by a nearly complete coalescence of bract and scale, wingless pollen and spiral phyllotaxy. The extinct species greatly outnumber the existing and the family has evidently passed its climacteric stage and seems destined to extinction. Moreover none of the genera have more than three existing species (*Athrotaxis*), three have but two (*Sequoia*, *Taxodium*, *Glyptostrobus*), and four have but one (*Sciadopitys*, *Cunninghamia*, *Taiwania*, *Cryptomeria*). Their restricted range is also an indication of former greatness. Thus *Glyptostrobus* is Chinese, *Sciadopitys* is Japanese, *Taiwania* is confined to Formosa, *Cunninghamia* and *Cryptomeria* are Chino-Japanese, *Athrotaxis* is Australian, *Sequoia* is confined to the Pacific and *Taxodium* to the Atlantic border of North America. The family is unrepresented in Europe, South America or Africa at the present time. Its fossil history constitutes one of the romances of paleo-

botany illustrating the antiquity, growth to cosmopolitanism and subsequent wane of the various types. The oldest known genus that appears to represent this family is the Permian and Triassic *Voltzia*, with dimorphic distichous foliage, long, slender, cylindrical cones of imbricated three to five lobed sporophylls, and two or three winged seeds. There are at least half a dozen species known and they are recorded from Europe, Asia and South America, but not certainly from North America.

Another ancient and truly cosmopolitan genus was *Cheirolepis* with distichous twigs, short pointed leaves and five lobed two-seeded sporophylls. A genus of doubtful affinities is *leptostrobus* of the Jurassic of Asia and North America, although *Sequoia* appears toward the end of that period (Portlandian). In the Lower Cretaceous the more noteworthy genera are *Sphenolepis* and *Athroxopsis*, although *Sequoia* is undoubtedly represented by foliage, cones and structure material at widely separated localities.

The Upper Cretaceous genera are *Geinitzia*, which may belong to the Araucariales; *Ceratostrobus* and *Microlepidium*, European genera; *Cunninghamiostrobus*, a Japanese genus based upon structural cone material; *Cunninghamites*, which had numerous species in Greenland, Europe and North America; and *Sequoia* which is abundant and recorded from all the continents except Africa and Australia, and from Spitzbergen on the north to Graham Land on the south. During the Cenozoic, especially during the older Tertiary, *Sequoia* continued unabated and is recorded from all the continents except Africa. *Athrotaxis* is recorded from Europe, *Cryptomeria* is found in Europe and the Arctic, while *Taxodium* and *Glyptostrobus* are found everywhere throughout the northern hemisphere in the greatest abundance, and both genera are still present in Europe as late as the early Pleistocene.

The most obvious characteristic of the family Cupressaceæ is the cyclic arrangement of the reduced leaves, a feature which, acquired early in their history, has continued unchanged from the Cretaceous to the present. The cones are small and are hard or fleshy at maturity. The existing genera are nine in number and contain about 80 species, of which 40 per cent belong to the genus *Juniperus*. The smaller genera show apparent anomalies of distribution coupled with an extended history.

There are a number of Mesozoic genera of which *Brachyphyllum* (*Echinostrobus*) is the most prominent and including *Raritania*, *Thuites*, *Androvettia* and presumably *Moriconia* and *Inolepis*, which have been investigated anatomically and which show various combinations of the following features: sclerotic pith, lateral pits of ray cells, branched leaftraces, mucilaginous resin canals, uniserial spaced bordered pits of the tracheids passing into alternating and sometimes mutually flattened series, transfusion tissue not lateral to the foliage strands but showing a tendency to surround the phloem. These and other features are regarded in some quarters as indicating that these genera are descended from the Abietineaceæ and should be included in the order Araucariales—a view that has received but slight acceptance and one that is dissented from in the present article.

The family history goes back to Widdringtonites of the Triassic, and to *Palaeocyparis* and *Brachyphyllum* of the Jurassic. These are not altogether conclusive in their testimony, but the family springs into unquestionable prominence during the Upper Cretaceous at which time in addition to *Brachyphyllum*, *Thuja*, *Thuites*, *Juniperus* and disputed genera like *Androvettia*, *Moriconia* and *Inolepis*, there were well-marked species of Widdringtonites, and *Frenelopsis* in which the foliar features are substantiated by fructification characters, which in the case of the valvular cones of the *Actinostrobinæ* are unmistakable. The genera *Callitris*, *Cupressus*, *Chamaecyparis* and *Libocedrus* appeared in the Eocene, while many of the Cretaceous genera survived into that time and attained an extended range.

The family *Abietinaceæ* is characterized by almost completely distinct bract and scale, by winged pollen, short shoots, needle leaves and various recondite anatomical features of unproven phylogenetic import. They are admittedly the most complex morphologically, and are usually regarded as the most modern family of *Coniferophytes*, although some students consider them to represent the ancestral stock from which the *Araucariales*, *Taxales* and the *Taxodiaceæ* and *Cupressaceæ* have been derived by reduction. Whichever view finally prevails there can be no question but that in the light of present knowledge they have much the shortest geological history. There are nine genera and about 125 existing species, of which more than half belong to the genus *Pinus*, and they form extensive forested areas in the North Temperate Zone, to which they are practically confined. Extinct genera are rare and include the Upper Cretaceous *Prepinus*, *Entomolepis* and *Plutonia*. Among the still existing genera *Pinus* has numerous extinct species and goes back to the Lower Cretaceous (*Pinites* or *Abietites*). *Cedrus* goes back to the Lower Cretaceous, *Picea* and *Abies* to the dawn of the Upper Cretaceous, while *Tsuga*, *Pseudotsuga* and *Larix* are exclusively Tertiary and Recent. The family is especially varied and widespread in the relatively short period from the Oligocene to the Recent.

Angiospermophyta.—In contrasting the angiosperms with the coniferophytes or with any of the other great groups of seed plants one is impressed with the lack of knowledge of both recent and fossil forms. Making their appearance in the geological record during the Lower Cretaceous they soon outdistanced all competitors and from the Eocene to the present they have been the dominant plant group. Over 100,000 existing species are known and the fossil forms, even in the relative short period of their dominance, probably outnumber the recent, so that vast numbers of species and very imperfect knowledge render a generalized presentation impossible. The angiosperms undoubtedly show the most perfect adjustment of the plant organism to a strictly terrestrial existence. Adaptable to a degree unequaled in other phylæ they inhabit the most diversified environments and some have secondarily invaded the sea margins as well as the lakes and streams, while others have become parasites, saprophytes or epiphytes. The modification of their flowers for securing cross pollination through the agencies of insects or birds

is well known as are the various modifications of fruits and seeds for dispersal by wind, mechanical ejection, floating, passing unharmed through the alimentary tract of birds or mammals, sticking or clinging to fur or feathers, etc. (see articles *CROSS FERTILIZATION*; *DISPERSAL*). Ranging in size from tiny aquatics to giant trees several hundred feet tall and ranging in their life span from that of a single season to several thousand years they are the most impressive members of the vegetable kingdom. Fruits are confined almost exclusively to angiosperms and are apparently one of the effects of fertilization as specializations for protection and dispersal of the seeds. The variety of fruits is almost as great as that of flowers and must be considered an important factor in the success of the angiosperms as well as one of their prime benefits to humanity. It seems more than a coincidence that the evolution of a group of plants of the capacity of the angiosperms in which, as in some of the cereals, 30 per cent of the total weight of the plant is stored as elaborated food in the seeds, should have been contemporaneous with the evolution of the warm-blooded animals. At any rate it seems certain that human civilization could not have evolved but for the evolution of this plant phylum. The angiosperms are so numerous and present so many morphological diversities that it is impossible to give a succinct characterization (see articles *BOTANY*; *SEED PLANTS*). Their outstanding feature is angiospermy itself, i.e., pollination results in bringing the pollen spores in contact with a receptive surface of the carpel (stigma) and not with the ovule, as in all other known seed plants. All known angiosperms have closed ovaries and no other phylæ have. At the same time it should be recalled that angiospermy was itself a product of evolution and that some time a series of fossil forms may be discovered showing this character in the formative stage. Anatomically angiosperms are characterized, the dicotyledons normally and the monocotyledons primitively by the vascular system of the stem constituting a tubular cylinder (siphonostele) of collateral bundles and having leaf gaps. The wood is marked by the presence of vessels arising through cell fusion—a feature common to the gnetalean coniferophytes and one absent in certain specialized families of angiosperms such as the *Cactaceæ* and *Crassulaceæ* and in other possibly primitive families such as the *Trochodendraceæ*. The improved conductive and supporting tissues of the angiosperms result in a general improvement in storage tissues and in a great expanse of foliage and consequently a greatly increased production of nutritive materials. These histological features as well as the floral morphology to be alluded to presently are features of the sporophyte generation. The history of the male gametophyte does not differ materially from that which obtains in the various gymnosperm phylæ but the female gametophyte is not only more reduced but its development is associated with new and peculiar features. Free nuclear division in the egg is wanting (a feature common to *Gnetum* and *Tumboa* among the *Gnetales*). The process of what is commonly called double fertilization is a strictly angiospermous characteristic. Among the units organized in the embryo sac is what is known as an endosperm nucleus. One sperm unites

with the egg nucleus and the result of this union is the embryo, the second sperm nucleus unites with the endosperm nucleus and the result of this union is the trophophyte or endosperm which furnishes the nutriment for the developing embryo and the subsequent germinating plantlet. This course of events is strikingly uniform throughout the phylum and is unknown in other plants. Those who consider the formation of seeds as the most important characteristic of a definite group of vascular plants (Spermophyta) ignore the history of the origin of the seed habit and the result is no more natural than the Exogenous and Endogenous classes or than one which attempted to use homospory and hespory to define natural groups of the remaining vascular plants. Moreover such a treatment is confronted with the necessity of defining a flower. If a flower is considered as a group of sporophylls in order to include the gymnosperms it then includes many of the so-called flowerless plants. If, on the other hand, the gymnosperms are placed in their correct perspective and a flower is defined as a group of sporophylls associated with a perianth the limit of the flower corresponds almost exactly with the limits of the phylum (except Gnetales) and the necessity, if such exists, for abandoning the convenient term flowering plants, as some students have advocated, is obviated. The popular concept of a flower is too firmly entrenched to warrant any attempt to arrive at a more philosophical morphology and the fact that the floral envelopes are lacking either primitively or by reduction in some groups is no more pertinent than the fact that some flowers consist entirely of floral envelopes and lack sporophylls. The presence of floral leaves (calyx and corolla) surrounding the sporophylls and derived both from sterilized sporophylls and bracts appears to have been conditioned largely by the habit of entomophily. Although the primitive floral envelopes were probably protective in their function certainly their subsequent history and great diversity of detail are the result of entomophily. In the more primitive flowers the sporophylls tend to be free and the axis tends to be elongated with the members in a spiral arrangement. Evolution of the flower proceeded along the lines of reduction in axial length until the members passed to a cyclic arrangement when they tended to become definite and fewer in number and at length became confluent to a greater or less degree. The three marked stages are termed hypogynous, perigynous and epigynous and all grades of intermediate stages are present. Inequalities of growth result in other diversities. The members tend to evolve from a radial symmetry (actinomorphic) to a bilateral symmetry (zygomorphic) or to an isobilateral symmetry with two planes of symmetry and with the halves unlike.

Systematists segregate angiosperms into two series — monocotyledons and dicotyledons, and there has been almost endless discussion as to which line was the more primitive. Both were present in the Cretaceous so that history fails to shed any light on the problem. Formerly gymnospermous and other remains from the older rocks were thought to represent monocotyledons but none such are now recognized. Modern opinion tends in the direction regarding the distinctions between these two groups

as largely cumulative and that the number of the cotyledons and the correlative characters are of less phylogenetic importance than was formerly believed. The view is here advocated that the angiosperms are strictly monophylatic, that the monocotyledons are not primitive, nor did the primitive angiosperms exhibit combined monocotyledonous and dicotyledonous characters, but that the dicotyledonous type is the more primitive, and that it has given rise to the monocotyledonous stock, not, however, as a single or monophyletic line of evolution but by one such line combined with several reduction series derived from different regions in the dicotyledonous plexus. Systematists have long recognized the similarities between the monocotyledonous arums, pondweeds and screw pines on the one hand and the dicotyledonous peppers and willows on the other, as well as the convergence of certain Ranalian groups and the water plantains. The case of the water-lily family is a classic instance of a group of dicotyledonous origin which has essentially reached the monocotyledonous category. Analogies between the amphisporangiate "flowers" of the aberrant Cycadeoideas of the Mesozoic and such dicotyledonous flowers as those of the Magnolia have furnished a basis for a theory of angiosperm descent which while fascinating is believed to be illusory. More definite evidence for a revival of the old view that the angiosperms are related to the gymnosperms through the amentiferous dicotyledons and some gnetalean type similar to *Gnetum* has recently been accumulated. This evidence comprises the character of the inflorescence, the floral morphology, the details of sporogenesis, fertilization and embryogeny, the organization of vessels in the wood, the broad rays, companion cells in the bast, the habit and foliage, the dicotyledonous embryo, the elimination of archegonia and the organization of eggs. The foregoing considerations are derived entirely from a study of recent forms since no certainly determined fossil forms of Gnetales are known, and no known fossil angiosperms throw any light upon their phylogeny.

The taxonomy of the angiosperms is still in a most unsatisfactory state. The chief steps in their classification have been taken by Ray (1703), Jussieu (1789), De Candolle (1819), Endlicher (1836-40), Brongniart (1843), Braun (1864), Bentham and Hooker (1862-83), Eichler (1883) and Engler (1892). While very imperfect and founded to a too great degree upon floral morphology the classification proposed by Engler and derived largely from Eichler is the most satisfactory, and it has the additional advantage of having been elaborated as a comprehensive systematic treatise (see article BOTANY, CLASSIFICATION). The Monocotyledons and Dicotyledons may now be briefly characterized. In the former many of the forms are herbaceous which argues for modernity. Anatomically the bundles are closed (amphivasal), are without cambium, and are scattered through the parenchymatous ground mass of the central cylinder. Sometimes the bundles indicate a primitively circular arrangement such as obtains in the dicotyledons and the theory that a tubular central cylinder with foliar gaps was an ancestral condition accords with the view of phylogeny here advocated,

This does not mean, however, that the monocotyledons are strictly modern and monophyletic. The flowers tend to be trimerous and chalazogamy has not been observed. There is a greater reduction of sporogenous tissue in the megasporangium. There is one seed leaf or cotyledon which is terminal in position while the stem tip is lateral. The leaves are poorly differentiated into blade and stalk and tend to be entire, sheathing and lack stipules. The venation is closed and the primary and lesser systems are so sharply contrasted that the leaves are commonly considered parallel veined, and even when the latter feature is less obvious as in the arums and many tropical forms the contrast in calibre just mentioned remains obvious. In the dicotyledons the stem shows a tubular

and hence prevailingly netted veined and this results in all degrees of lobation and division of the laminae.

Historically the oldest known angiosperms are found in the Lower Cretaceous of Greenland, North America, Europe and New Zealand. These earliest known types do not appear to be primitive (only the foliage and secondary wood structures are known), and an extended early but unknown period of evolution seems to be demanded. By the close of the Lower Cretaceous both monocotyledonous and dicotyledonous angiosperms are not uncommon. These include palms and most of the principal families except the most specialized such as the orchids among the former and the composites among the latter. A second modernization of

cylinder (siphonostele) of collateral bundles, a persistent cambium form secondary phloem and xylem, both of which elements arise through cell fusion. Secondary thickening results in a relatively larger display of assimilative tissue (foliage) and a branching habit. The cotyledons are two in number and lateral in position and during germination the growing points and cotyledons are liberated by the elongation of the hypocotyl as contrasted with the monocotyledonous tendency to free the root and stem tip by the elongation of the cotyledon which functions as an absorbing organ suggestive of the "foot" of pteridophytes. The dicotyledonous flowers tend to be four or five merous. The leaves are well differentiated into petiole, blade and frequently stipules are present. The venation is graduated and open

the flowering plants took place at the dawn of the Tertiary and a third modernization in the Miocene. The Miocene floras were much like those of the present, but were richer in arborescent types and the forms were more widely distributed than they are at the present time. The bulk of the herbaceous vegetation appears to have been relatively modern in its evolution and those large groups or parts of groups that are especially characteristic of existing temperate floras, such as the Cruciferae, Boraginaceae, Labiatae, Compositae, Umbelliferae, Krameriaceae, Papilionaceae, etc., were relatively very modern and their main evolutionary deployment seems to have been largely Pleistocene and post-glacial. The subject is much too large for treatment in the present article but a somewhat full discussion of the geological history of the

angiosperms will be found in the 'Proceedings' of the American Philosophical Society (Vol. LIII, pp. 129-250, 1914).

Conclusion.—The mutual relationships of the various groups of vascular plants that have been briefly discussed in the preceding paragraphs are shown in Fig. 5, which aims to represent graphically their phylogeny as understood by the writer and their relative importance throughout geologic time.

EDWARD W. BERRY,
Professor of Paleontology, Johns Hopkins University.

PALEOCENE, the lowest (oldest) epoch of the Cenozoic Age, embracing in North America the Puerco and Torrejon beds of New Mexico, and the Fort Union formation of the region east of the northern Rocky Mountains. None of these are marine formations, and it is believed that at this period the continent had substantially its present outlines and mountain ranges; but the Appalachians were worn almost to levelness, and the plateau and mountain region on the Pacific slope were much less elevated than now. It is probable that Asia and Alaska were connected by land. The climate was semi-tropical in character, and the interior of the country contained large lakes and water-courses. "Vast stretches of subtropical and more hardy trees were interspersed with swamps where the vegetation was rank," says Osborn, "and accumulated rapidly enough to form great beds of lignite. Here were bogs in which bog-iron was formed." The animal fossils show a general resemblance to Mesozoic types, and consist largely of reptiles, such as huge turtles, crocodiles, lizards, with many fresh-water shells. The conditions at the time in South America seem to have been much the same; but in Europe the fossils of the Paleocene show that many of the beds were of marine origin,

and that the climate was cooler than in America. Consult Scott, 'Land Mammals in the Western Hemisphere' (New York 1913).

PALEOCLIMATOLOGY. Climatology treats of the changes in the atmosphere, geographically and in time. At the basis of these variations is temperature, and the source of the heat is nearly all solar. The earth is internally hot, but almost nothing of this heat attains the surface. It has been well said that the atmosphere is a kind of blanket put about the earth to keep it warm. The reason for this is that the air is transparent to those rapid vibrations of ether received from the sun which we know as light. On reaching the ground, however, a considerable portion of the light is transformed into much slower vibrations, which we perceive as heat. Now if there were no atmosphere, these heat vibrations would pass off into space and be lost; the result would be that the burning heat of the unmodified sunlight would be turned into almost the intense cold of outer space at night. This is prevented by the atmosphere, which retains the heat and thus moderates and equalizes the temperature on the surface of the earth. Of the various gases which compose the atmosphere, the oxygen and nitrogen are transparent to both the quick light vibrations and the slower heat ones; they could not therefore alone modify temperature in any great degree. The carbonic acid gas and especially the water in the air, on the other hand, while transparent to light, are more nearly opaque to heat vibrations, and it is due to them that the heat is retained. The larger proportion there is of them in the air, therefore, the more equable will be the temperature. This explains why deserts, with their dry atmosphere, suffer such changes of temperature between day and night, while the moist atmosphere of oceanic islands gives them such even climates.

It must not be understood that all sunlight is thus turned into heat, as a portion is absorbed in passing into the atmosphere and another part is reflected back as light and not transformed; it is the remaining portion that is thus effective.

The effects of the atmospheric changes not only condition the geographic distribution of the kinds of life, but also react physically and chemically on the lithosphere, so that the weathering of the rocks and soils is different in the cold and warm and in the wet and dry areas. It is well known that the mechanical alteration of rocks is greatest in cold climates, high altitudes, and deserts, while the chemical changes are most marked under warm, moist conditions. In fact, an abundance of moisture in warm climates stimulates a rich vegetal and bacterial growth that liberates much carbonic acid, and this, along with the oxygen of the air, brings about the highly decomposed soils of tropical lands.

The surficial areas of the present isothermal climatic belts, according to A. Supan, are as follows:

	Warm zone	Temperate zones	Cold zones
Northern hemisphere....	53.3	31.8	14.8
Southern hemisphere....	45.4	45.1	9.5
Average.....	49.3	38.5	12.2
or as 8 is to 3 and 1			

Paleoclimatology, on the other hand, is the study of the succession of climates, as observed in their reactions on the inorganic and organic materials throughout the geologic ages. The methods of study in the two sciences are therefore very different. In climatology, observation is direct, for we are living under the influence of the actual climates and so can study their character and effects upon the things alive and dead, while in paleoclimatology the atmosphere is not present, and the methods of study are indirect and determined from its operations upon the plants and animals of the past and upon the earth's sedimentary rocks.

During the first half of the 19th century, it was assumed by most astronomers and geologists that the earth began as a star, a small, hot, self-luminous body. In the course of time, the earth was said to have slowly cooled, and finally to have become non-luminous and encrusted, attaining only very recently its cooled climate and polar ice caps. We therefore see that the older geologists believed that the climates of the past were warm and equable the world over; the idea that the earth had recently passed through a glacial climate came into general acceptance only during the latter half of the previous century. More recently geologists have learned that the earth has had many cooled climates, most of which were localized, while at least three were glacial ones, affecting the whole earth. We now know, moreover, that the climates of the geologic ages have varied much, and through the added results attained by biologists and paleontologists regarding the biological regions of the warmth-loving plants and animals, it is seen that a new science—paleoclimatology—is in development.

The plants and animals are also self-registering thermometers, and the marine "life thermometer" indicates vast stretches of time of mild to warm and equable temperatures, with but slight zonal differences between the equator and the poles. The great bulk of known marine fossils are those of the shallow seas, and the evolutionary changes recorded in these 'medals of creation' are slight throughout vast lengths of time that are punctuated by short but decisive periods of cooled waters and great mortality, followed by quick evolution, and the rise of new stocks. The times of less warmth are the *miotherm* and those of greater heat the *pliotherm* periods of Ramsay.

On the land the story of the climatic changes is different; but in general the equability of the temperature simulates that of the oceanic areas. In other words, the lands also had long-enduring times of mild to warm climates. Into the problem of land climates, however, enter other factors that are absent in the oceanic regions, and these have great influence upon the climates of the continents. Most important of these is the periodic warm-water inundation of the continents by the oceans, causing insular climates that are milder and moister. With the vanishing of the floods somewhat cooler and certainly drier climates are produced. The effects of these periodic floods must not be underestimated, for the North American continent was variably submerged at least 17 times, and over an area of from 154,000 to 4,000,000 square miles.

When to these factors is added the effect upon the climate caused by the periodic rising of mountain chains, it is at once apparent that the lands must have had constantly varying climates. In general the temperature fluctuations seem to have been slight, but geographically the climates varied between mild to warm pluvial, and mild to cool arid. The arid factor has been of the greatest import to the organic world of the lands.

It is seemingly clear that the variability in the storage of solar radiation by the earth's atmospheric blanket and by oceanic waters and the consequent climatic variations of the past and present are due in the main to topographic changes in the earth's crust. These superficial changes alter the configuration of the continents and oceans, the air currents (moist or dry), and the oceanic currents (warm, mild or cool).

On the other hand, a great deal has been written about the supply and consumption of the carbonic acid of the ancient climates as the primary cause for the variable storage of warmth by the atmospheric blanket. A greater supply of carbon dioxide is said to cause increase of temperature, and a marked subtraction of it to bring on a glacial climate. This aspect of the climatic problem is altogether too large and important to be entered upon here. It is permissible to state, however, that the glacial climates are irregular in their geologic appearance, are variable latitudinally, as is seen in the geographic distribution of the tillites between the poles and the equatorial region, and finally that they appear in geologic time as if suddenly introduced. These differences do not seem to be conditioned in the main by a greater or smaller amount of carbon dioxide in the atmosphere, for if this gas is so strong a controlling factor, it would seem that at least the glacial climates should not be of such quick development. On the other hand, an enormous amount of carbon dioxide was consumed in the vast limestones and coals of the Cretaceous, with no glacial climate as a result; though it must be admitted that the great limestone and vaster coal accumulations of the Pennsylvanian were followed by the Permian glaciation. Again it may be stated that the Pleistocene cold period was preceded in the Miocene and Pliocene by far smaller areas of known accumulations of limestone and coal than during either the Pennsylvanian or Cretaceous, and yet a severe glacial climate followed.

Briefly, then, we may conclude that the markedly varying climates of the past seem to be due primarily to periodic changes in the topographic and geographic forms of the continents and oceanic areas, plus variations in the amount of heat stored and distributed by the oceans.

The factors in paleoclimatology are four in number, and stated in the order of their historic development are as follows:

(1) *Tillites*.—Glaciers of to-day deposit in front of themselves either sheets of glacial boulder clays or moraines that are composed of heterogeneous materials such as unconsolidated sand and muds and rocks that are subangular and rounded along with others that are faceted and striated. These are the glacial tills of the Scotch geologists, while the ancient ones of like origin, but now consolidated into hard rock formations, are known as tillites.

Our knowledge of glacial climates had its origin in the Alps and chiefly through the studies of De Charpentier between 1815 and 1834, and of Louis Agassiz beginning in 1836. From their teaching we now know that alpine glaciers and vast continental sheets of ice, thousands of feet thick, covered widely many parts of the world, not only polar lands but temperate parts as well, during the Glacial period. Through a study of the present glaciers and the work they do in spreading the tills far and wide over the lands as they melt and retreat, geologists have learned to discern in the tillites their significance as to the former glacial and locally cooled climates. Curiously, in early Permian time glaciers were widely spread to the north and south of the equator and not at all in northern temperate and arctic areas, resulting, however, in cool and semi-arid climates in North America and northern Europe. In fact, tillites are known as far back in geologic time as the early Proterozoic, and others are present in formations deposited in Ordovician, Silurian, Devonian and Eocene times.

(2) *Paleontology*.—On the basis of the present distribution of life (zoogeography), paleontologists have long been aware, through their studies of the fossils, that variations in the climates of the past may be discerned more especially in the higher plants, insects, corals, shelled cephalopods and foraminifers. When explorers in Arctic America brought the information that whole beds of limestone in that region are made of Silurian corals, and that in the Tertiary of Greenland occur leaves of the bread-fruit tree and other warmth-loving plants, it became apparent that these places must at times have had warm climates like those of Italy and Florida at present. In the course of a century of biologic and paleontologic endeavor paleontologists have learned much regarding the zonal distribution of ancient life. Therefore when they encounter an abundance of fossil corals and especially coral reefs and limestones made up of large forms of foraminifers in far northern lands such as Alaska and Spitzbergen, they regard this as conclusive evidence that the waters in which they lived were warm. Marine reefs of the present and past, built by calcareous algæ, sponges, calcareous hydroids, corals and tubiculous worms, and banks of thick-shelled bivalves, are all known to be indicative of warm and shallow waters. Gastropods with thick calcareous opercula are evidence of the same nature. Marine shell faunas in great variety of forms are of warm waters, while in cool to cold ones there is usually a great duplication of but a few species. Assemblages of large insects point to warm climates, while small ones show reduced temperature. Large-shelled cephalopods, like those of the Ordovician, Silurian, and more especially of the Jurassic and Cretaceous, bespeak warm waters.

On the lands, ringed woods are nearly always indicative of climates with winters, while palms, tree ferns, cycads, magnolias, figs, planes, tulip and bread-fruit trees are of warm climates. Trees and shrubs occur in far less variety under cool climates than is the case in warm ones. Turtles, snakes, lizards and dinosaurs do not live in cold climates, while mammals are in

greatest variety in temperate areas and in the semi-arid regions of the tropics.

(3) *Topography and Paleogeography*.—Geologists have long been pointing out that the earth's history is cyclic or periodic in nature. For very long times the lands are low and more or less widely flooded by the oceans. Then the climate throughout most of the world is oceanic, that is, it is warm, moist and nearly uniform. The lands are base-leveled and the geologic formations are essentially of the seas and oceans. Thin deposits and widespread limestones and calcareous shales are characteristic of these times, along with the formation of coal beds. Subsequently the earth for a time loses its isostatic balance and readjusts itself through internal rearrangements. The lands in relation to the strand lines are then higher and much larger, while their borders are apt to be elevated into mountain chains, and the climates are cooled or may become even glacial. Zonal and arid climates, from tropical to cold, are prevalent. The oceanic overflows are then also least in area, and the geologic formations, because of accelerated erosion, tend to be coarse and of greater thicknesses, together with the presence of fresh-water deposits that are usually barren of fossils and often red in color. It is essentially at these times that gypsums and salts and glacial deposits are laid down. The organic world then also loses its ecologic balance, is stimulated to change, and forced to readapt itself through evolution to the altering environment.

The climates of entire areas may be greatly altered by the formation of some new land or mountain range, or through the birth of a land-bridge uniting two continents, for these may divert or even bar air and oceanic currents. Think, for instance, of what would happen to northwestern Europe if the Panama bridge were deeply beneath the sea so that the equatorial currents flowing into the Caribbean would pass into the Pacific. There would be no Gulf Current to warm western Europe, and it would be as cold and inhospitable as Labrador. When mountain ranges are high, they divert the air currents and extract from them their moisture, causing one mountain side to be moist while the other may be more or less arid. And it may make a great deal of difference to the local climate as to how the mountains trend. Finally, when most of the continents are large, high and mountainous, as at present, then the earth has cooled to glacial climates.

(4) *Petrology*.—Johannes Walther was one of the first to direct attention to the sedimentary formations of the ancient seas, and more especially to those formed by fresh water and by the air, as having within themselves a climatic record. He pointed out that the deserts of central Asia are red in color, that carmine-red dunes are wandering across Arabia, while yellows are of wide distribution in Trans-Caspia and in Africa. In temperate regions, the soils are chiefly gray, yellow or brown in color, while in tropical ones they are red and the laterites are brown-red. In America Joseph Barrell has written much on the same subject. It is now evident that the color and chemical content of the geologic formations are largely connected with climate. Alternations in color from red deposits to gray and white sandstones

and conglomerates, with coal beds such as occur in the American Carboniferous succession, appear to indicate wide swings of climatic change from warmth and semi-aridity to cooled, humid and probably even cold climates. Accumulations of salts and bedded gypsums are indicators of dry climates, while widespread formations of limestones are looked upon as evidence of warm-water seas. On the other hand, coal beds are usually regarded as formed in swamps under temperate to cool climates. Loess is accumulated dust blown out of the deserts into moist grass-covered areas. Finally, all mudstones that are "sun-cracked" are evidence of seasonal exposing and the drying out of the contained water by the atmosphere. This phenomenon is particularly common in the oxidized red formations that were laid down under more or less arid climates. Through an understanding of the present operations of the laws of nature, we thus learn how to discern their effects throughout the geologic ages, and to see that the rocks, like the living organisms, have within themselves the records of their originations and something of their ancestral histories.

CHARLES SCHUCHERT,

Professor of Paleontology, and Curator of the Geological Department, Peabody Museum of Natural History, Yale University.

PALEOGEOGRAPHY. Geography is the science which describes the earth's surface, including the distribution of the living things upon it at the present time, and more especially of mankind, the dominating influence among the organisms. Paleogeography, on the other hand, treats of the succession of geographies of the past, i.e., the prehistoric geographies, as known to geology and paleontology. In other words, paleogeography is the synthesis of the earth sciences based on the record of the rocks of the earth's surface. The term paleogeography was first used by T. Sterry Hunt in 1872 for "the geographical history of ancient geological periods," but it is only since 1896 that it has come into wide usage.

When, in the beginning of the 19th century, geologists began to perceive the vast significance of the doctrine of the Scotch geologist Hutton, who taught that "the ruins of an earlier world lie beneath the secondary strata," and, further, that great masses of water-deposited rocks have been upheaved and thrust into mountain ranges, only to be later worn away by atmospheric agencies, it was but natural for them to look for the lands that had furnished the materials of these upheaved rocks. In this way the science of paleogeography had its origin, but because of the scantiness of geologic knowledge a century ago, the embryo science was almost wholly of a descriptive and not of a cartographic nature.

The French were the first to discern paleogeography, and it was Élie de Beaumont, between 1829 and 1852, who led the way by pointing out that the water-laid rocks had been elevated from time to time and pushed up to form the mountain chains of the earth's surface. We now know that where the seas have endured for many millenniums, and in the geosynclines of the continents where vast thicknesses of strata have accumulated, here later on a mountain range will rise and a new land be formed. The cause of these periodic risings of the moun-

tains is the continual shrinking of the earth's mass, resulting in the shortening of its circumference, and in the buckling up of its surface into mountain ranges. When an over-ripe apple dries out and becomes smaller in mass, its skin wrinkles, and in the same way the earth shrinks into a smaller mass and its surface from time to time wrinkles into mountain ranges. These great changes in the earth's surface also bring about alterations in the atmosphere, and at times even produce severe glacial climates that affect the whole earth outside of the tropical regions. Furthermore, because of these changes, there come about marked alterations in the evolution and distribution of life.

The evolution of the earth's surface is cyclic in nature. During the longer part of each cycle, the lands are being leveled and reduced to a peneplain, and at these times the oceans flood the continents most widely. The long accumulations of shrinkage constantly going on within the earth attain the breaking stage, and the resulting movements produce on its surface high lands and mountain ranges. Then the seas begin to retreat more and more and are drawn into the oceanic basins, the continents at the same time attaining their largest size and greatest altitudes. In this way erosion again becomes active and another cycle of deposition and continental flooding is started. The sands and muds and the solution materials of the rivers are but the fragmented and dissolved mountains and high lands in transit to the oceans. For every grain of land transported into the marine waters, there is just so much water displaced. The result is that during the long quiet second part of the cycles, when the earth's crust moves but little, the oceans are constantly rising and flowing ever more widely over the continents. The oceanic level at rare intervals is also lowered by hundreds of feet over wide areas in the tropical region by the subtraction of the water and the piling of it upon the land as ice in the polar and temperate regions. The closing events of the cycles, or, better, periods of time, are known as the "disturbances," but during some of them mountain making was by no means localized, for mountains may have been elevated almost simultaneously in several continents or even throughout most of the world. The times of widespread mountain making are known as "revolutions" in the history of the earth. In general it may be said that as the earth periodically shrinks, the lands become widely elevated in relation to the strand-line, while the oceans subside in compensation to the reduced mass.

More than 17 such cycles are recorded in geologic history in North America, and in this way the continent has been flooded over areas varying between 154,000 and 4,000,000 square miles by great inland shallow seas. These facts show how greatly the geography of the geologic past has been undergoing change. To-day we are living in the last phase of the first part of a new cycle, and the oceans have already begun their spread over the continents, as is demonstrated by the inland or marginal seas such as Hudson Bay, North Sea, Baltic Sea, and the continental shelves that border all continents.

Élie de Beaumont, at least as early as March 1831, in his geologic lectures in the College of France and at the Paris School of Mines, used

to outline to his students the relation of the lands and the seas in the centre of Europe at the different great geologic periods. His first printed paleogeographic map appeared in 1833, and in the following year the Sicilian geologist Gemmellaro published six maps of Italy and De La Beche one of England. In America the first to show paleogeographic maps was Arnold Guyot in his Lowell lectures of 1848, but it appears that James D. Dana was the first to publish such maps, three of which were included in his epochal work of 1863, the *Manual of Geology*. Of world paleogeographic maps, Jules Marcou published the first one in France in 1866, but the most celebrated of these early greater attempts was the well-known map published by the Viennese paleontologist Neumayr in 1883.

Since 1833 there have appeared not less than 500 different paleogeographic maps, and of this number about 210 relate to North America. Nevertheless, paleogeography is still in its infancy, and most of the maps embrace too much geologic time, all of them showing the changes that transpired during tens of thousands, and some of them during millions of years. Mariners' maps show the conditions of the strand-lines at the times of their making, and those made even 50 years ago have to be revised again and again if they are to be safely followed by the coastal navigator and by the engineer. Therefore paleogeographic maps should ever tend toward depicting smaller amounts of geologic time, if they are to show the actual relation of water to land and to illustrate the movements of the periodic floodings. Moreover, the ancient shore lines of the paleogeographic maps are all more or less hypothetical and are drawn in sweeping curves, unlike modern strands with their islands, bays and headlands. Also the ancient lands are usually drawn as almost featureless, and only rarely do the maps indicate the probable drainage. In the course of time, paleogeographic maps will show the features of the lands, such as the mountain ranges and volcanoes, the climatic zones, and something as well of the distribution of the life of the time depicted, while the seas will be shown with their probable depth, temperature and currents.

As yet, no one has attempted to picture the geographies back of the Cambrian—a vast time almost devoid of recognizable fossils. This means that all of our attempts are limited to the last half of geologic time, which has an abundance of fossils in formations that usually have not been greatly altered by the dynamic forces of the earth's moving crust or lithosphere.

Paleogeography is the synthesis essentially of the sciences of geology and paleontology. The discerning of the ancient geographies is based mainly on eight factors. These, stated in the order in which the data are used, are as follows:

(1) *The Formations*.—The units in geology are the geologic formations, masses of rock either stratified or unstratified, of one kind or of various kinds, formed in the seas and oceans or on the lands, with or without fossils, and composed either of sediments, conglomerates or igneous materials. Their present geographic distribution is the first basis for deciphering the geographies of the past.

(2) *Superposition*.—The geologic age of a

formation is determined first through superposition. It naturally follows, if in a given area there are several superposed formations which have not been disturbed through crustal folding, that the lowest one must be older than those above. Also that when they are cut by igneous rocks these crystalline masses must be younger than the formations through which they rose when molten.

(3) *Paleontology*.—In general practice, when a formation has fossils, these, along with superposition, determine its limits and its geologic age. Fossils are the basis of most geologic chronology, because all life is in the constant state of change comprehended under the term organic evolution. The individuals change into different species or even genera, and the species of an assemblage die out or migrate elsewhere or are added to by the introduction of new ones of local origin or by immigrants. In other words, the organic assemblages constitute a series of automatically placed time cards. Therefore any fauna or flora indicates more or less accurately the geologic time of its existence. Fossils, furthermore, tell much about the environment in which they lived, whether in the seas or oceans, on the lowlands or highlands, in the swamps, rivers or lakes, and whether the climates were cold, temperate or tropical. In all of this the paleontologist is guided by the distribution of life as it is at present, and by the Hutton-Lyell principle that at all times the laws of nature have operated uniformly and as we see them to-day.

(4) *Petrology*.—The petrologic factor shows the significance of the macro- and microstructure of the rocks. Through the operation of the phenomena of the present, the geologist is guided in his interpretation of the rocks, as to whether they were formed in the water or by the winds, in the seas and oceans or in the rivers and lakes, or on the dry lands under pluvial or arid climates. Also as to the probable depth of water in the seas, the amount of its agitation, and whether the rocks were formed near to or far from the shores. The environment automatically impresses itself upon the accumulating sediments, just as it brings about the evolution of all living things.

This method also distinguishes the igneous or once molten rocks from those of sedimentary origin, and helps to point out not only the proximity of volcanoes, but, what is far more important in paleogeography, the former position of mountain ranges now all eroded away except their roots.

(5) *Diastrophism*.—The geologic record of the lands is locally a discontinuous one, but in the inaccessible ocean basins it is probably continuous. Consequently what any geologist sees is but a fraction of the record, and these fragments of knowledge he pieces together into one continuous geologic history, embraced in historical geology. Everywhere the geologic sequence is full of "breaks," which are also known as "intervals" of time, when no record was being made other than that of erosion. These breaks or intervals have shown that the recording goes on now here and now elsewhere, and that it is periodic and cyclic in nature, as discussed earlier in this article.

(6) *The Time Factor*.—Geologic time is exceedingly long, measured by human standards.

The Paleogeography of Early Cretaceous Time (Benton Formation) in North America.

On the basis of radium disintegration, it appears that geological work has been going on for at least a billion years. This factor then emphasizes the importance of the breaks in paleogeography, and directs attention to them as representing land intervals that endured thousands or even millions of years.

(7) *Permanence of the Oceanic Basins.*—In the first half of the 19th century it was widely held that all parts of the oceans had been

land, and that all of the lands had been beneath the sea. The latter half of this statement is now known to be true, for over most of the continents occur marine strata, though they are almost exclusively those of shallow seas. Not more than 1 per cent of them are deposits like those of the great oceanic depths, and because of this fact the belief is now general that the continents have never been covered by deep oceans. In other words, the continents

of to-day have always existed, but it does not naturally follow that they have always had their present shape. The truth is, rather, that from time to time their outlines have been greatly changed by the overflowing oceans, and at times they may have been united to each other by land-bridges (q.v.), like that of Panama to-day.

The oceanic basins appear to be the most constant features of the earth's surface, and while their shallow-water areas have changed much in the course of geologic time, yet the actual or deeper parts of the oceanic basins have long had about the shapes that they have at present. The Pacific has been the most constant in shape, as it seems that the Atlantic and Indian oceans greatly altered their outlines during Paleozoic and Mesozoic times. Because of the increase of water with time, it is also probable that all of the oceans have increased somewhat in area, and in depth as well.

(8) *Present Geography*.—The present geographic map is the base over which is drawn a given paleogeography. The time will come when but one geography will be shown, and that will be the paleogeography of the time illustrated by the map, but for some time yet the present geography is necessary for the orientation of the ancient one.

CHARLES SCHUCHERT,
Professor of Paleontology and Curator of the
Geological Department, Peabody Museum of
Natural History, Yale University.

PALEOGRAPHY, or **PALÆOGRAPHY**, pā-lē-og-rā-fī, the study of ancient handwriting from surviving examples: distinguished from Epigraphy in that Paleography takes cognizance of writing executed with such instruments as a reed (*calamus*) or a style (*stilus*, *graphium*) on papyrus, waxed tablets, parchment or other substances, which in different ages have fulfilled the uses of paper, while Epigraphy has to do with inscriptions cut in stone, metal or other enduring materials. Sometimes the term Paleography is employed in a wider sense, as comprehending the art of reading ancient writings and such a critical knowledge of all their circumstances as will serve to determine their age, if they happen to be undated, and their genuineness in the absence of any formal authentication. For these purposes the paleographer needs to be acquainted with the various substances, such as bark, leaves, skins, paper, etc., which have been used for writing; with the various manners of writing which have prevailed and the changes which they have undergone; with the various forms of authenticating writings, such as seals, signets, cachets, signatures, superscriptions, subscriptions, attestations, etc., which have been employed at different times with the various phases through which the grammar, vocabulary and orthography of the language of the writing with which he is dealing has passed; and with more or less, as the case may be, of the history, laws, institutions, literature and art, of the age and country to which the writing professes to belong.

Of ancient Greek and Roman written documents a certain number have come down to our time; and selections from these as well as from later manuscripts are used in this article to illustrate the sort of materials that form the subject matter of Paleography. These writings

are, so far as the most ancient ones are concerned, on papyrus or on waxed tablets, while the less ancient documents are on vellum or on paper. (See PAPER; PAPHYRUS; VELLUM). The tablets as used by the Greeks and Romans—called by the Greeks *deltoi*, *deltidia*, *ptyktoi*, *pinakes* and by the Romans, *tabulæ*, *tabellæ*, *pugillares*, *cera*, were usually of wood, but sometimes of ivory; they had a raised margin round the edges and the surfaces were covered with a thin layer of wax—hence the name commonly given to them by the Romans, *cera*, plural form of *cera*, wax: the Greek names all mean thin boards, tablets, and *deltos*, *deltidion*, furthermore indicate one of the original forms of such tablets—that of the Greek letter Δ. The tablets were used for temporary memoranda as we use slates; for use in schools they were usually strewn with sand, instead of being covered with wax. Two or more tablets held together by rings or other fastenings which served as hinges were termed by the Romans *caudex* or *codex* (block of wood), or, according to the number of tablets so held together, *cera duplices*, *triplices*, *quadriplices*, *quintuplices*, etc., book of two, three, four and five tablets; by the Greeks a two-leaved book of tablets was called *pinax triptychos*, *tetrptychos*, *pentaptychos* and so on.

The history of Greek Paleography, so far as it can be written from extant materials, begins with B.C. 3d century and ends with the close of the 15th century and the introduction of the art of printing. During that period Greek handwriting is seen to have passed through two phases—that of the uncial or large letter and that of the minuscule or small letter; the beginning of the 9th century marks the time of transition, though naturally survivals of the antiquated uncial letters may be noted in documents long subsequent to the year 800, and on the other hand anticipations of the minuscule not a few are seen in manuscripts dating from an earlier period. Both the uncial and the minuscule are seen in two styles—the set, or more formal, and the cursive. The difference between the capital letters and the uncial is no doubt a result of the difference in the materials upon which the inscriptions were made. When the letter E (epsilon) was to be carved on stone or bronze, it was manifestly easier to give it that form than the uncial form ε; the same is to be said of Σ (sigma) and Ω (omega); but in writing with a style on a waxed tablet, or with a reed or a quill pen (the use of the latter can be traced no farther back than the 6th century) on papyrus or parchment, the uncial form is the more convenient; and as the transition from capitals to uncials was due to the difference of materials on which the inscription was made, so no doubt the change from uncial to minuscule is, at least in part, due to the general use of vellum and later of cotton and linen paper.

The earliest examples of Greek uncial writing extant have been discovered in Egypt and in the ruins of Herculaneum and they are on papyrus. Those from Herculaneum are certainly of a date not later than A.D. 79, when the town was destroyed; probably they were all written during that century. Of the papyri from Egypt there are a few whose downward date-limit is accurately ascertained. The earliest Greek manuscripts extant were discovered at the vil-

lage of Kurob, Egypt, by Flinders Petrie, of the University of Dublin, 1890. These are of a date certainly prior to B.C. 235, and comprise fragments of classical writings and records of a probate court, some dating from the reign of the 2d Ptolemy, the rest from the reign of the 3d Ptolemy. Of the handwriting of these documents Professor Mahaffy of Dublin says that it "varies from large, clear, splendid writing to the most fugitive and illegible cursive." Prior to Petrie's discovery the most ancient Greek manuscript document extant was an astronomical work entitled *Ἐβδοξον τεχνή*, now in the Louvre collection. This has, written on the back, deeds bearing dates equivalent to B.C. 160; the writing is in set uncials of simple style, executed with a fine light stroke, without exaggeration of forms in the letters; in these respects it seems a fair type of the writing in vogue during the second or third centuries preceding the Christian era. In a tomb near Monfalat was found, 1849, a fragmentary papyrus containing portions of the 'Iliad'; it dates from not later than B.C. 1st century; the text is in slender uncials, very regular. The Louvre collection contains also fragments from the 'Iliad,' which date from perhaps the 2d century of our era. A fragment of poetic lines, supposed from the lost Temenides of Euripides, together with a few lines from the Medea, is in the private library of Firmin-Didot, bibliopole, of Paris, the date of which is not later than B.C. 161, a document of that year having been added. One of the most important discoveries hitherto made of Greek papyri in Egypt is that of one containing two orations by Hyperides, now in the British Museum; it is a roll, 11 feet long, in unusually good preservation. The writing is elegant, in set uncials, which, however, are often linked together without raising the pen; this document is certainly not more recent than B.C. 1st century. The Herculaneum Greek papyri are usually written in neatly-formed and regularly-spaced uncials.

Of tablets inscribed with Greek uncial writing, very few have come down to us. There are two in the British Museum. These are from Memphis and on one are traced some verses in large, roughly-formed letters, whose date can only be conjectured to fall within the 1st century of our era. In the Cabinet des Medailles at Paris is a set of five tablets on which are scribbled alphabets; also, in a more current hand, a contractor's accounts. Finally, a tablet from which the wax is worn has inscribed upon the wood characters in ink: it dates probably from the 4th century.

The firmer and smoother surface of vellum favors a more exact style of writing and a firmer hand, but no Greek manuscript on vellum of a date earlier than the 4th century is known to exist. The earliest examples of manuscripts on vellum are the three famous codices of the Bible and of these the conjecturally most ancient—the Codex Vaticanus is probably of the 4th century. The writing, in its original condition, must have been very perfect as a specimen of penmanship but nearly the whole of the text has been traced over by a later hand, probably in the 10th or 11th centuries, a small number of words only being left untouched. Written in characters of uniform size, without enlarged initial

letters, the manuscript has all the simplicity of great antiquity. The Codex Sinaiticus (q.v.) bears the same tokens of antiquity and is by its discoverer, Tischendorf, judged to be older than Vaticanus, but the writing of Sinaiticus is not so pure as that of Vaticanus and if that is a criterion of age, Vaticanus is the older. The Codex Alexandrinus (see ALEXANDRIAN VERSION) is referred to the middle of the 5th century; it has enlarged letters at the beginnings of paragraphs; the writing is more elegant than that of Sinaiticus. In all three codices we find simplicity and regularity the leading features; the round letters are formed in symmetrical curves; **Ε** **Ϛ**, etc., finishing off in a hair-line, thickened at the end into a dot; horizontal lines fine, those of **Ε** **Η** and **Θ** being either in the middle or high in the letter; the base of **Δ** and the cross-stroke of **Π** also fine, and as a rule, kept within the limits of the letters and not projecting beyond,

From the 5th century there have come down to us fragments of an illustrated Homer, in which the writing is somewhat taller than in the three codices, the cross-stroke in **Ε** is abnormally low down, the stem of **Ρ** (Rho) is

ΤΕΚΝΩΝ ΣΟΥ ΤΕΡ ΠΑΤΟΥΝ
ΤΑΣ ΕΝ ΑΛΘΕΙΑ ΚΑΘΩΣ ΕΝΘ
ΛΗΝ ΕΛΑΒΟΜΕΝ ΑΠΟ ΤΟΥ ΠΑΤΡΟΣ

Greek Uncial (Cod. Alex.), 5th Century.

(τεκνων σου περιπατων
τας εν αληθεια καθως ενθ
λην ελαβομεν απο του πατ[ρ]ος).—2 John 4.

not produced below the line. To the same century is probably to be referred also the palimpsest Codex Ephræmi, an incomplete New Testament with the letters imperfectly erased, and homilies of Ephræm Syrus written over them (see PALIMPEST); the Octateuch, whose leaves are divided between Paris, Leyden and Saint Petersburg; the illustrated Genesis in the Cottonian Library; and the Dio Cassius of the Vatican.

The uncial writing of the 6th century shows signs of degeneration in larger characters, more heavily formed and not so completely written, cross-strokes in such letters as **Α**, **Δ**, **Π**, **Τ**, produced and terminating in heavy points. The *Dioscorides* at Vienna is the type of the 6th century uncial writing. Other manuscripts of the 6th century are a palimpsest Homer and palimpsest fragments of Luke, with Syriac text written above both; palimpsest fragments of Matthew and Isaiah, at Dublin; fragments of the Pauline epistles from Mount Athos; a copy of the Gospels written in silver and gold on purple vellum the leaves of which are scattered among several libraries; fragments of the 'Eusebian Canon'; the Coislin 'Octateuch'; and the Vienna 'Genesis.'

A new style of Greek uncial writing appears in the beginning of the 7th century, round letters becoming oval and the other letters laterally compressed; the writing slopes to the right, and accents and breathings are introduced. The slanting style continued in use through the 8th and 9th centuries. These characteristics (except the accents and breathings) are seen in the following facsimile of two lines from a mathe-

Latin uncial writing differs from the capital in the rounded forms of A, D, E, H and M, as seen in the accompanying specimen, except that here the bow of the A is in most places "blind." Another point of difference is, that in the uncial some of the letters rise above or fall below the line. The earliest specimens extant belong to the 4th century and in them the writing is so well established that we may believe it to have been already practised for generations. Uncial writing persisted as an ordinary book-hand, till in the 8th century it was supplanted by the reformed small writing of the Carovingian school. Examples of uncial writing are the Vercelli 'Gospels,' a palimpsest Cicero 'De Republica' in the Vatican, and a fragment of a commentary on an ante-Hieronymian text of the Scriptures at Fulda. All of these are of the 4th century. From the 6th century are the two codices of Livy, at Paris and Vienna, and the Gaius at Verona.

semble those of the more cursive *graffiti* found on the walls of Pompeii.

Roman Cursive (Graffiti), 1st Century.
(censio est nam n. ster
magna habet pecuni[am]).

Roman Cursive (Dacian Tablet), 167 A.D.
(descriptum et recognitum factum ex libello —
erat Alb[urno] maiori ad statione Rescuii in quo scri —
id quod i[n]fra s[criptum] est).

In this early cursive hand are seen the beginnings of minuscule writing. The slurring of the strokes, whereby the bows of the capital letters were lost and their more exact forms modified, led the way to the gradual development of the small letters. The letter A is formed by a main stroke supporting an oblique cross-stroke above it; so too P and R having lost their bows, and F, throwing away its bar, are formed by two strokes placed in relatively the same positions, but varying in their curves. The main stroke of B dwindles to a slight curve, and the two bows are transformed into a bent stroke or loop to the left of the long stroke, so as to resemble our script d. This form of B persists in cursive writing till the 6th century. The D resembles the uncial form of that letter; the E is represented by the old form || found in inscriptions and in the Faliscan alphabet. The G in the Dacian tablet shows the first outline of the g of later writing; in the *graffiti* the H, by losing the upper half of its second upright limb, comes near to being the small h. In the Pompeian tablets (as also in the *graffiti*) M has the four-stroke form. In the Dacian tablet it is a rustic capital, almost an uncial M. The O is formed by two strokes almost like a.

From the date of the Dacian tablets to the 5th century no specimens of Roman cursive writing exist. Fragments of two imperial rescripts in cursive writing on papyrus are extant, in which are seen the same characters as in the Dacian tablets, with certain differences and modifications; but they are even more difficult to read than the latter. The same is to be said of another fragment dating from 572.

Roman writing of the different styles—capital, uncial, half-uncial and cursive—became known to the Western nations and formed the basis of the different national styles of writing known as the Lombardic, the Visigothic and the Merovingian. An important influence in determining the ultimate forms of our print and script characters was the reform of writing instituted by Charlemagne 789. The abbey of Saint Martin of Tours was the principal centre

(Iam tibi illa quæ igno-
rantia saecularis bo-
nia opinatur ostendam).

* Between uncial and cursive lies the style "half-uncial." Apparently as early as the 4th century a set style of small writing was in use, which partly followed in its formation the characters of Roman cursive writing, while in some of its letters it retained the uncial forms. It appears in marginal notes on some early

Episcopimanu minnoceñei
quam non ad falsiloquium cog
nationem unteyoriñrenti

Latin Half-Uncial, 509-510 A.D. 1

(episcopi manum innocente[m] —
[lin]guam non ad falsiloquium coeg[isti] —
nationem anterioris sententi[æ] —) .

manuscript. But beginning with the end of the 5th century there is extant a series of manuscripts written wholly in this hand. In the specimen here given the B, D, M, N, R and S are seen to approximate in form to the same letters in Latin minuscule writing. The agreements with uncial are patent.

Of Roman cursive writing we possess specimens dating from the 1st century of our era. In a box unearthed, 1875, in the house of L. Cæcilius Jucundus, at Pompeii, were found 27 *libelli* or waxen tablets containing records of various legal transactions; and at different times, 1786-1855, 25 other waxen tablets, some dating from A.D. 131, were found in ancient mines at Verespatak (anc. Alburnus Major, in Dacia). In both sets of tablets the writing is much alike, and the forms of the letters re-

from which the reformation of the book-hand spread. In the 9th century the minuscule had attained a degree of elegance and clearness that left little to be desired, as appears from the following specimen:

accipere marium coniugem tuam quod
enim ex ea nascetur de spiritu sancto est. Pariet
autem filium et uocabis nomen eius iherum

Caroline Minuscules, 9th Century.

(accipere mariam coniugem tuam quod
enim ex ea nascetur de spiritu sancto est. Pariet
autem filium et uocabis nomen eius iherum).

From that style to our modern characters, whether script or print, was an easy step.

Paleography may be said to have been founded by the learned French Benedictine, Jean Mabillon, whose 'De Re Diplomatica' (1681, fol.; reprinted 1709 and 1789, in 2 vols. fol.) is still, perhaps, the most masterly work on the subject. With the 'Nouveau Traité de Diplomatique' (Paris 1750-65, 6 vols. 4to) of the Benedictines of Saint Maur, and the 'Eléments de paléographie' (Paris 1838, 2 vols. 4to) by M. Natalis de Wailly, is the great authority for French paleography. English paleography is perhaps less favorably represented in Astle's 'Origin and Progress of Writing' (London 1803) than Scottish paleography in Anderson's and Ruddiman's 'Diplomata Scotiæ' (Edinburgh 1739). Muratori treats of Italian paleography in the third volume of his great work, 'Antiquitates Italicæ Medii Ævi'; and among later works on the same subject may be mentioned 'Diplomatica Pontificia' (Rome 1841) of Marino Marini. The paleography of Greece is illustrated in 'Paleographia Græca' (Paris 1708) of Montfaucon. Spanish paleography may be studied in 'Biblioteca de la Poligrafía Española' (Madrid 1738) of Don C. Rodriguez. Of works on German paleography it suffices to name Eckard's 'Introductio in Rem Diplomaticam' (Jena 1742), Heumann's 'Commentarii de Re Diplomatica' (Nuremberg 1745), Walther's 'Lexicon Diplomaticum' (Göttingen 1745) and Kopp's 'Paleographia Critica' (Manheim 1817). Hebrew paleography has been elaborated by Gesenius in 'Geschichte der Hebräischen und Schrift' and other works. The great work on paleography generally—one of the most sumptuous works of its class ever published—is 'Paléographie Universelle' (5 folio vols., Paris 1839-45) of M. J. B. Silvestre.

E., 'How to Decipher and Study Old Documents: A Guide to the Reading of Ancient Manuscripts' (London 1893); Wailly, J. N. de, 'Eléments de paléographie' (Paris 1838); Quaritch, B., 'Catalogue of Manuscripts and Books Illustrating the Science of Paleography' (London 1893).

PALEOLITHIC PERIOD, The. The second period of prehistoric man is the Paleolithic (Greek, *paleos*, ancient, and *lithos*, stone), the first period being the Eolithic. In this stage of his development man made his implements of flint by chipping off flakes until the desired form was obtained, but as far as known he never polished them afterward, the art of polishing stone implements being introduced near the beginning of the Neolithic. It is on this basis,—the absence of polished stone implements in the deposits of the Old-Stone Age and their presence in those of the Young-Stone Age,—that the names Paleolithic and Neolithic are given. The makers of Paleolithic implements probably did not belong to a single race of men, but rather to several races. Of these races two seem to have been especially important: the Neanderthals, who lived during the older Paleolithic and the Cro-Magnons, who replaced them, and who seem to have been the dominant people of the younger Paleolithic. In general, it can be said that during the period under discussion man became progressively more dextrous in making stone implements and that toward its close, when bone and ivory were replacing stone, skill in working flints declined.

Proofs of Antiquity.—Great difficulty is often encountered in determining the age of the remains and implements of paleolithic man; many mistakes have been made and investigators have differed widely as to the interpretation of the same evidence. Nevertheless, when all the evidence is carefully studied, it is found that the broad outlines of the history of the Old Stone Age can be accepted, even though the details are sometimes in doubt.

The proofs of man's antiquity and the relative age of his remains and implements are determined by several lines of evidence:

(1) The association of his remains and implements with the bones of extinct animals is a convincing proof of man's antiquity when it can be established that these bones and tools were deposited at the same time. For example, in France, England, and elsewhere the bones of extinct elephants, rhinoceroses, lions, and other animals are found with the remains of man. In other deposits the arctic woolly rhinoceros, woolly mammoth, and reindeer are found with his skeletons and tools. These animals have long been extinct in the countries in which their remains are now found, and the climate in these countries has radically changed since then.

(2) The proof of the age of man's remains is also afforded by deposits in caves as the relative age of his implements and bones is shown by the superposition of the layers in which they occur. No one cave affords a complete record of the Paleolithic Period, but by piecing together the evidence from different caves the relative antiquity of cave deposits has been unraveled, so that it is now often possible to tell the age of the deposit from the stage of development of the implements, as well as from the animal remains. A single example, that of Kent Cavern, Devonshire, England, will suffice to illustrate this method of determining the relative age of deposits. As the material which partly filled the cavern was excavated, three distinct layers were encountered, in addition to two sheets of stalagmite, a rock formed by lime dripping from the roof of the cave.

(a) The surface was composed of dark earth containing mediæval remains, Roman pottery, and objects of iron, bronze, and stone, showing that man inhabited the cave at intervals from Neolithic to Roman times.

(b) Below this surface layer was a bed of stalagmite one to three feet thick. This covered a reddish deposit known as cave-earth, which contained a number of relics made of stone, bone, and horn. The flints were shaped into tools designed for various purposes. The bone implements were in the form of pins, awls, barbed-harpoons, and neatly formed needles. Associated with these implements were the bones of extinct animals, among which were fragments of the skeletons of the cave hyena, horse, rhinoceros, gigantic Irish deer, wild boar, bison, mammoth, cave bear, cave lion and sabre-tooth tiger. All of these animals are of species now extinct, not only in England, but throughout the world.

(c) The bottom of the cave was filled with broken fragments of rock (breccia) containing the remains of the cave bear, together with flint implements of a much cruder type than those in the layers above.

It is evident from this description that thousands of years were required for the filling of this cave. The bones of bygone animals that either had their lairs in the cave or whose carcasses were dragged there by ancient extinct carnivores is proof of the great antiquity of the lower deposits. The last of these animals, so far as we know, disappeared many thousands of years ago. The thickness of the stalagmite beds formed by lime drip is another evidence of the antiquity of the underlying deposits. A bed of stalagmite, one to three feet thick, probably required a very long time for its formation, although favorable conditions might have caused a rapid deposition. The oldest of these deposits are many thousands of years old, but ancient as they are they were, nevertheless, laid down long after the ape-men had disappeared from the earth.

(d) In the valleys of the river Thames in England; or the Somme, Marne, and Seine in France; of the Inn in Austria; of the Rhine in Switzerland, and in the valleys of other European rivers are found series of terraces or benches. A careful study of these terraces shows that during glacial times the rivers flowing from the great ice sheets spread vast deposits of sand and gravel over the broad surfaces of their valleys. In many valleys these deposits were built to a height of 100 to 150 feet. Several times during the Glacial Period the ice sheets advanced, and at other stages, called interglacial, the glaciers practically or entirely disappeared from Europe and North America and the climate in these continents became warmer than it is at present. During these interglacial stages the streams flowing through the valleys are believed to have had smaller volumes and much less sand and gravel in proportion to the volume. Consequently they were able to cut into their ancient beds, forming narrower channels, through which they transported their own loads of sediment. In this way successive river terraces were formed, a descending series of gigantic steps along the sides of the valleys. In many valleys there are four of these terraces which correspond to the several glacial stages; in others

there are only three terraces. In general "the high terraces" are the oldest ones. The coarse river gravels of the high terrace of the Eure, for example, contain remains of an extinct elephant and of an extinct horse, showing that these animals lived when a broad stream carrying coarse gravel flowed at least 90 feet above the present stream. It is in or on the gravels of the high, middle, and low terraces and underlying the materials later deposited on them that the artifacts of man are found. Along the river Seine the "high terrace," 90 feet above the present level of the river, corresponds to the first glacial stage, whereas the "low terrace" is only 15 feet above the river and was built of gravels deposited much later when the river was nearly of its present size. The "high terrace" contains the bones of animals of the first interglacial stage, but none of man nor of man's stone implements, whereas the lower terraces have yielded flints of prehistoric man and the bones of more recently extinct animals.

(e) During parts of the second and third interglacial stages, the climate of Europe was arid and the fine dust of the glacial deposits was swept up and transported by the wind until it slowly settled over the continent. The time at which these dust or loess deposits were laid down can be dated by the fossils they contain and also by the stage in the development of the flint implements embedded in the loess, and the loess, in turn, when its age is known on other evidence, gives the age of the human, artifacts.

(f) The tools which man made were gradually improved as he acquired greater skill and had better models to copy. Consequently, the older implements are, in general, cruder than the later ones or of a different type. Such evidence must be carefully weighed, however, since the skilled worker of later times occasionally discarded a partially worked flint because of some flaw in the stone and sometimes lost a flint which had been merely roughly fashioned. Such crude, unfinished flints have sometimes led to the belief in a greater antiquity than they possess.

Climate.—Geological evidence points to the Glacial Period as the time when paleolithic man lived in Europe and Great Britain. The Glacial Period, or Great Ice Age, was not a period of continuous cold but, as has been said, included stages when the ice largely withdrew from the continent. These are called interglacial stages. It seems well established that the Great Ice Age in Europe consisted of four glacial and three interglacial stages, and that it was during the second or third interglacial stage,—more likely during the third,—that paleolithic man reached Europe.

The fossils of animals and plants found with the remains of very ancient men (Chellean and Early Acheulean) show that the climate was warmer at that time than it is now in England, France, and Germany. The southern mammoth (*E. meridionalis*), straight tusked elephant (*E. antiquus*), and soft nosed rhinoceros (*R. merckii*), hippopotamus, sabre-tooth tiger and hyena indicate that the climate was genial. The leaves of the sycamore, maple, willow and Austrian pine, found in deposits of the third interglacial stage near Paris, denote a temperate climate, and an increasingly milder climate is indicated by the presence of the box,

fig tree, and canary laurel in slightly later deposits. The habit of these last two trees of flowering in winter shows that the winter temperature was not cold. The plants of still younger deposits (late Acheulen) show that the climate was again becoming colder. The increasing cold finally culminated in what is called the Fourth Glacial Stage. It was during this time of refrigeration that the men of the younger Paleolithic Period lived.

CLASSIFICATION OF THE PALEOLITHIC PERIOD.

Various classifications of the Paleolithic Period have been offered, each of which is based upon important principles. It has been divided into the Age of the River Drift Man and the Age of the Cave Man. These divisions rest on the observation that the implements of the earlier Paleolithic Period are more frequently found in the gravels of river terraces than in caves and that later ones are found chiefly in caves and rock shelters. As the animal and plant remains of the earlier Paleolithic indicate a genial climate, so the chief occurrence of older paleolithic implements on the terraces formed by the rivers of the time seems to signify that in this stage man lived principally in the open, probably protected only by crude shelters of bark, as did the recently extinct Tasmanians. As the climate became colder with the approach of the Fourth Glacial Stage, more adequate protection was sought and that afforded by cave and rock shelters common in portions of Europe was used. These caverns and rock shelters were inhabited at least during the colder parts of the year. It is evident, however, caves and rock shelters would be used not only when the temperature was cold but also that when the climate was genial: for example, as a place of refuge during rain storms or when attacked by wild beasts or human enemies.

If the Paleolithic Period is divided according to the races which lived at the time, the terms Older and Younger can be advantageously used, since during the Older Paleolithic (Chellen, Acheulean, Mousterian) Europe was inhabited by the brutish Neanderthal men with their broad, flattish skulls and ape-like postures. The men of the Younger Paleolithic (Aurignacean, Solutrian, Magdalenian) were represented by the Cro-Magnon race, characterized by great heads, large stature, and modern aspect.

Another classification is based upon the conspicuous animals of the various stages.

Epoch of the Reindeer — Magdalenian

Epoch of the Mammoth and Woolly Rhinoceros (R. tichorhinus) — Mousterian

Epoch of the straight tusked Elephant (E. antiquus) and *Merck's Rhinoceros* (R. merckii).

The classification now generally accepted is based both on the characteristics of the races and upon their culture. It is as follows:

Old Stone Age: Paleolithic Period

Younger Paleolithic

Azilian

Magdalenian

Solutrian

Aurignacean

Older Paleolithic

Mousterian

Acheulean

Chellean

Prechellean

Eolithic Period

Eolithic.—If man had suddenly appeared on earth in his present bodily and mental state it would perhaps be unprofitable to search for his beginnings, but such was not true. Man was evolved from lower animals and his skill in making stone implements was acquired slowly and laboriously. Because the ability to design and shape implements was of slow growth, it is evident that very early in his history the tools he used were those prepared for him by nature, such as he found in the river bed or in the shingle of the ocean shore. The difficulty of determining whether such fragments were intentionally broken by primitive man or were shattered by the forces of nature is evident. His requirements in the way of tools being very simple and the supply of material in the form of natural flakes and fragments of flint being very plentiful, the inventive powers of man remained dormant for ages. The stone hammer and the stone knife were the original tools. Both were picked up ready-made. A sharp-edged, natural rock fragment served for one, and a nodule or fragment served for the other. When the edge of the flake became dulled by use, the piece was either thrown away or the edge was retouched for further use. If hammer or flake did not admit of being held comfortably in the hand, the troublesome points or edges were removed or reduced by chipping. The stock of tools increased slowly with the slowly growing needs. As these demands multiplied and the natural supply of raw material diminished, the accidental flakes were supplemented by the manufacture of artificial flakes. The earliest stone implements are called *eoliths* and the period, the *Eolithic period*. It is a significant fact that in gravels of "the higher terraces" *eoliths* have been found but no true paleolithic implements. It is possible that *Pithecanthropus* (see MAN, PREHISTORIC RACES OF) was a maker of crude flint implements (*eoliths*) and probable that the Heidelberg and Piltown men also made *eoliths*. Weapons and tools made from wood, however, without doubt, were the principal ones, just as they are with the gorilla to-day; but as they rapidly decay no trace of them remains.

Pre-Chellean Epoch.—Crude flint implements believed by some investigators to antedate the first well-established epochs of the Paleolithic (the Chellean) but to be subsequent to the Eolithic, are considered by others to belong to the Chellean. The general shape of the flint was due to chance and was adapted to a variety of purposes by crude flaking. It is possible that these stone tools were made by the Heidelberg and Piltown races.

Chellean Epoch.—The first well-defined epoch of the Paleolithic is the Chellean, named for the village of Chelles on the banks of the Seine, about eight miles east of Paris, where many implements have been found in alluvial gravels which form a terrace. The Chellean culture also occurs at Saint Acheul near Paris, in England, and in Spain. In all of these deposits are found flints shaped by man in his early efforts to master his environment. As one would expect, these first attempts to fashion flints into implements are very crude, but it is evident at a glance that the workers were endeavoring to make tools of a definite form. The most distinctive implement of the

Chellean, as indeed it is of the next following epoch, has been given several names (*coup-de-poing*, *boucher*, *faustkeil*, *hand-stone*). The French term, *coup-de-poing*, which literally translated means "stroke of the fist," is the one in most common use. "Hand stone" has been suggested as an English equivalent. This tool is roughly almond-shaped, varying from about 4 to 10 inches in length, and in size and shape is not unlike two hands with the palms touching. The form varies greatly from somewhat disc-shaped and oval to poniard shaped. It is a rather heavy tool which could be used for many purposes. A thick butt end fitted the hand and when held by this end it could be used for hacking or sawing, for drilling holes, for cutting and stabbing, for scraping hides, and for other purposes. When held by the pointed end it could be used as a hammer. If it had been used with a helve or handle the edges would have been chipped off by the violent blows it received, but the flakes produced by wear are minute and not coarse. The *coup-de-poing* was, in fact, the one indispensable, "all around" implement. The gravel deposits of Saint Acheul alone are said to have yielded 20,000 specimens. It was almost the sole implement used by the men of Chellean times. "It was the outcome of long experience, and, in point of utility, combined the functions of the elaborate array of mechanical tools which ultimately, under changed conditions of life, came into requisition." (Munro). In fashioning *coups-de-poing* a large number of flakes were broken off. The shape of some of the flint fragments was slightly modified by breaking off a corner or an edge and in this way a variety of small, crudely-made tools were obtained.

In the course of time flint tools were made for special uses and the use of the *coup-de-poing* was consequently gradually discontinued. This development in the skill of working stone, however, was very slow and during the whole Chellean Epoch flint implements were crudely shaped.

No human skeletons of Chellean Age have been discovered. This is not surprising, as bones rapidly disintegrate when buried in gravels or left on the surface. The climate of France in this epoch was not very different from the present, as is shown by fossils of trees, leaves, and animals. Ancient elephants (*E. antiquus*), rhinoceroses (*R. merckii*), hippopotami and sabre-tooth tigers, however, indicate a slightly warmer climate than now prevails in the same region.

During Chellean times Europe extended far beyond its present limits, the English Channel did not separate England from France, and Ireland was joined to England. Spain was connected with Africa at Gibraltar, and Italy and Sicily were also joined to that continent. As a result of these land connections the Mediterranean then consisted of two inland lakes.

Acheulean Epoch.—Acheulean implements have been found in at least 30 localities in France, England, Spain, Portugal, Italy, Germany, Austria, Russia, and Poland. In fact, the Acheulean workers probably lived in all that portion of Europe not then covered by the great ice sheet. The name Acheulean was given to the epoch because the industry of the time is typically represented in the gravels of

the third terrace of the river Somme at Saint Acheul, France.

The implements manufactured by the men of Acheulean times are merely modifications of the Chellean. The *coup-de-poing*, or hand-stone, is more skilfully made and, with few exceptions, the entire surface is flaked, whereas in the Chellean stage a part of the surface of the nodule is retained. It is, in general, lighter than the older tool; and the edge, as a result of repeated chippings, is much better adapted for cutting. It is, however, not always easy to distinguish between the implements of the two epochs. In addition to the *coups-de-poing* are found planing tools, knives, drills, scrapers, and other artifacts whose use can merely be conjectured. It has been stated that from the beginning to the end of the Chellean and Acheulean there is not an implement that can be regarded as a weapon (Sollas). The explanation, apparently, is that the spears were made exclusively of wood as were those of the recently extinct Tasmanians. It has also been suggested that it was only after men began to live in caves that they took to hunting big game (Munro).

A large number of fragments of human bones and several entire leg bones were found in a recess in the banks of the Krapinica Brook, in Croatia, but there is doubt as to the age of these remains. Some investigators consider them to belong to the Acheulean epoch and others to the Mousterian.

During the greater part of the Acheulean epoch the animal life was practically the same as in the preceding epoch: the straight-tusked elephant, Merk's rhinoceros, a horse which is believed to be the ancestor of some of our modern draft horses, the hippopotamus, and other animals abounded. Besides the common Chellean animals were hyenas, brown bears, wild boars, and lions. Some of the lions and hyenas are ancestors of the cave types which appear in the succeeding Reindeer and Cavern epochs, i.e., in the Younger Paleolithic.

The climate of the earlier Acheulean, as shown by animal and plant fossils, was warm. This is also indicated by the distribution of the Acheulean camps which are, for the most part, in the open country on the divides between rivers and on river terraces. Later in the epoch a colder, dry climate is indicated by the plants preserved in the travertine of La Celle-Sous-Moret, near Paris. It is possible that before the close of the epoch the continental ice sheet of Scandinavia began to move southward. Some Acheulean implements are said to be associated with the remains of the woolly rhinoceros and mammoth, but this association does not necessarily prove that the climate in the vicinity of the river Somme was cold, but may indicate instead that these animals, whose natural habitat was near the front of the ice, at certain times roamed southward and mingled with warm temperate animals. That the climate in northern France was arid at times is proved by the presence of layers of wind-blown dust or loess, which cover the terraces of the rivers of northern France, southern Germany, and Austria.

Mousterian Epoch.—Because of the colder climate of the Mousterian epoch the folk of that time were forced to spend a portion of the year in caves and rock shelters; for this

reason their implements, hearths, remains of feasts, and their skeletons are preserved in much greater abundance and perfection than are those of the men of the preceding epochs. During the warm summer months they lived in the open country, as is shown by the occurrence of their implements in loess (dust) deposits and river gravels. Their remains occur in many places in Europe south of Scandinavia, the latter country being largely covered by the ice sheet of the fourth glaciation. Asia Minor also contains deposits of this epoch.

The name Mousterean was given to this epoch because of deposits found in the floor of a cave and under the cliff in front of it, at Le Moustier, on the Vézère River in southwestern France. There seems to have been a continuous residence in this cave during upper and middle Mousterean times and also during a part of the following (Aurignacean) epoch.

The Mousterean stone implements are modifications of those of the Acheulean but are superior in workmanship, variety, and design, and they were evidently made by the lineal descendants of the makers of the Acheulean implements. A change to a colder climate seems to have been the compelling cause for the improvement in the implements and the explanation for the little progress in the manufacture of stone tools in Acheulean times is ascribed to the sub-tropical climate which offered little incentive to exertion. When the climate became colder Mousterean man was compelled to leave the open country and seek such natural shelter as he could find, and so became a cave-dweller, a troglodyte. He was compelled to provide his body with some kind of clothing or freeze; the easily gathered and abundant fruits no longer supplied him with food and he was forced to hunt and having secured flesh to cook it. Necessity then required him to make tools of new design and better construction and some form of social organization must have arisen as the result of the living in caves. The *coup-de-poing*, or hand-stone, was still used, but this "all around" tool was gradually supplanted by implements designed for special purposes. A new method of manufacture, called the Levallois flaking, soon caused the disappearance of the *coup-de-poing*, because implements made in this way were lighter, had better cutting edges, were made with less labor, and served equally well many of the purposes of the older implement. The Acheuleans shaped the *coups-de-poing* from a nodule of flint by chipping off bits with a hammer stone until the desired form was obtained, but they had also learned to make the Levallois flake which was produced by breaking off a large flake so as to form one smooth, slightly convex surface. In preparing a nodule from which to manufacture the Levallois flake, the nodule was first dressed to the desired shape; then with a sharp blow a flake was detached which was later trimmed to final form. In Mousterean times this method of manufacture was perfected and Levallois flakes six to seven inches long and two inches wide were made. From similar flakes a variety of implements were made; one of these, the Mousterean point, rarely four inches long, was carefully retouched so as to form a sharp point. The Mousterean point was probably used for cutting, piercing, and scraping hides. Scrap-

ers of various kinds, awls and, for the first time, lance heads were also made. Spherical balls of limestone have been found which were probably used for bolas. Crudely made bone implements seem to have been manufactured in this epoch, but they are little more than bone fragments whose accidental shapes were useful.

A number of fragmentary skeletons of the makers of Mousterean implements have been unearthed and it is now possible to give an accurate description of the men of that time. The race is called the Neanderthal Race from a cave in a small valley of that name near Düsseldorf, Germany, where a skull of this race was unearthed. Remains of Mousterean men from at least 20 localities have been identified. These skeletons are all of men of one type; with large, broad, flat heads and strong jaws and teeth. (See MAN, PREHISTORIC RACES OF). The remains of Neanderthal men have been found only in caves but their implements have been discovered in terrace deposits indicating that they lived in the open during favorable weather.

The animals most characteristic of the Mousterean epoch are the mammoth, woolly rhinoceros, and the reindeer. The long hair which reached almost to the ground and the thick, soft, under-coating of fur shows that the mammoth was well adapted for a severe climate. (The food found in the stomach and mouth of frozen Siberian mammoths consisted of grasses, sedges, beans, and arctic crow-foot. In the winter the leaves and branches of small trees and shrubs were also eaten). The woolly rhinoceros (*R. trichorhinus*) was also protected by long hair and a thick under coating of fur. Besides these larger animals there were arctic foxes and hares, the banded lemmings and others. The occasional discovery of the remains of the straight-tusked elephant and Merck's rhinoceros indicates that either in the warm summer months or during intervals of warmer climate these southern animals migrated into Europe from the south.

The evidence from the character of the fauna and floras as well as the fact that man lived in caves instead of in the open during the greater part of the Mousterean, points to a severe climate which forced man from the open plains to such natural shelter as he could find.

The best evidence at present indicates the fourth glacial stage as the time in which the Moustereans lived. It is estimated that the Mousterean epoch lasted about 30,000 years and closed about 25,000 years ago (Osborn).

Geography.—The geography of Europe during Mousterean times differed somewhat from that of to-day. Scandinavia was covered with an ice sheet which extended a short distance south of the Baltic Sea, and England, for a time at least, was joined to France.

Aurignacean Epoch.—The older Paleolithic includes the pre-Chellean, Chellean, Acheuleans and Mousterean, and is succeeded by the younger Paleolithic, of which the first epoch is the Aurignacean. With the older Paleolithic, the Neanderthal race disappears and a new race or races of men appear, differing from it in physical appearance almost as much as the Neanderthals differed from the ape-man. The kinds of animals, however, remain nearly the

same, although their relative abundance varies somewhat at different times. The reindeer was common and because of its constant association with the remains and implements of younger Paleolithic man this division is often termed "the Reindeer Period." The horse, bison, cave bear, and cave lion, as well as other animals, were also living in the regions occupied by man in Europe. In Italy the Aurignacean seems to have been the only younger Paleolithic culture.

The love of personal adornment is shown in the perforated sea shells and back bones of fishes for use in necklaces, perforated teeth of various animals and beads made from ivory and reindeer horns which he wore. Bone tubes which served as flasks for pigment were made from the cannon bones of the reindeer.

Aurignacean man was the first to use bone to any great extent for making tools. From this material he made such implements as pins, chisels, and shaft-straighteners (first called *baton de commandements*). With him art seems to have had its beginning.

There was a marked improvement in the workmanship of the flint implements of this stage. One important flint was the graver (burin) used for making incisions in hard materials, such as stone, bone, horns, and ivory. Side scrapers (racloirs), end-scrapers (grattoir), flints shaped like a knife blade (châtelperron-point), spoke-shaves and tools of other designs were made. Figures in outline of horses, bison, rhinoceroses, elephants, stags and oxen represent crude attempts at art, but in some specimens the drawing is excellent.

During Aurignacean times the English Channel was not in existence and man could walk from France to England or Ireland without crossing any natural barrier, other than rivers. The Baltic Sea was reduced to a fresh water lake. During this epoch the climate in western Europe became dryer and less severe than it was in Mousterian times as is shown by deposits of loess.

Horses were abundant and were killed and eaten but, as far as known, they were never domesticated. Around one Aurignacean camp (Solutré) the bones of not less than 100,000 horses have been found. In this bone breccia remains of the reindeer and mammoth have also been unearthed.

The superb Cro-Magnon race appeared at the beginning of the Aurignacean and at about the same time the Neanderthals disappeared. It is probable therefore that the extermination of the latter was brought about by these new arrivals. Skeletons of the Cro-Magnon race have been found in France, Wales, Italy, Spain, and Austria. They were very tall men with an average height of six feet one and one-half inches and their brain capacity was larger than that of modern man.

Solutrean Epoch.—The Solutrean industry has an unexpected distribution in that it is not found in the lands bordering the Mediterranean. The artifacts of the epoch have, however, been found in England, France, Germany, Hungary, Bohemia, and Poland.

The Solutrean epoch is characterized by extraordinary skill in the manufacture of flint implements. At no other time in the Paleolithic was the fashioning of implements from flint so admirable. The most perfect of these

flints are laurel-leaf and willow-leaf spear heads. These implements are evenly flat and remarkably thin, so thin in some specimens as to be translucent; but the character which especially distinguishes them is the beauty of the secondary flaking (Solutrean retouch). In this process thin flakes were split off with great regularity, leaving long, shallow furrows which run from the edge of the implements up toward the middle; both sides of the laurel-leaf points have been dressed all over in this way.

Art which had such a promising beginning in the Aurignacean epoch was at a standstill, or even declined during the Solutrean epoch. The use of bone and ivory, however, continued, and bone and ivory arrow straighteners, spear points, awls, the first bone needles, and some primitive drawings and statuettes were made. The frequent occurrence among their remains of lumps of ochre and graphite shows that colors were used either for personal adornment, as was customary with the American Indians, or for paintings on the walls of caves. The sudden appearance of implements with the "Solutrean retouch" suggests that possibly a new race had invaded Europe. That this is probable is further shown by the discovery of a few skeletons (Brünn race) whose skulls are different from those of the Cro-Magnon race, and which are of as low a racial type as that of the Australian negroids. The skulls are unusually long for their width. This race did not drive out the Cro-Magnon race, but lived in Europe at the same time and from it the Cro-Magnons appear to have learned how to manufacture the beautiful Solutrean spear-heads. One possible cause for the lack of progress of art during this epoch is the slight amelioration of the climate which permitted man to live in the open, and, consequently, the incentive of the cave dweller for drawing and carving was lacking.

Magdalenian Epoch.—The culture of the people of the Magdalenian is so unlike that of the preceding epoch that it is difficult to understand how the high art of this epoch could have been made by descendants of the Solutreans. Instead of beautifully made flint implements, the inhabitants of the Magdalenian caves manufactured stone implements of inferior workmanship and often of poorly selected stone. But the lack of a highly developed flint industry was fully compensated for by tools made of bone, horn, and ivory. A great variety of new kinds of tools and ornaments of bone was soon invented and the skill in the manufacture of bone is as surprising as the lack of skill in the working of flints. In the early Magdalenian the bone implements were similar and less varied than later in the epoch. The bone implements most commonly found are spear-heads, which at first were without barbs, but later were made with a double row; bone spear throwers, shaft straighteners, and bone fish hooks. Bone needles were beautifully made and were much superior to those of later times. "The Romans, for example, never had needles comparable to those of the Magdalenian epoch." (Lartet).

The art of Magdalenian times attained a high degree of development. This is seen in carvings of animals on bone and ivory; in engravings on bone, on slabs of stone, and especially on the walls of caves and rock shelters.

The culmination of Magdalenian art is probably that found on the roof of the cave of Altamira in northern Spain, where a large number of figures, some of which are of life size, colored in black, red, yellow, and polychrome, representing bison, horses, deer, and other animals are found. The drawing is of a high order and could not have been executed by any but skilled artists.

It is probable that the Cro-Magnon race was the dominant one during the Magdalenian epoch, and that they were the artists of this time. More than 30 kinds of animals were portrayed by the artists and sculptors of this epoch and it is not surprising, perhaps, that the more impressive of them, such as the mammoth and bison—though perhaps not the most abundant—were favorite subjects. Besides these animals they drew or engraved the outlines of the rhinoceros, the horse, the ibex, the lion, the bear, and the deer. A few figures of women have been discovered but figures of men were rarely and crudely portrayed.

Azilian Epoch.—The Paleolithic period closed with the Azilian epoch. Instead of a form of art higher than that of the Magdalenian, better carvings, and tools of superior workmanship, such as one would expect, there is a deterioration in art and flint working. "With the advent of Azilian the realistic art of the Magdalenians disappeared and is succeeded by rude attempts at geometrical or generalized representations. There is no working in ivory; this material has disappeared with the mammoth, and stag's horns take its place" (Sollas).

Numerous pebbles have been discovered which are painted on one side with various designs; dots, parallel lines, ladder-like patterns, forms which resemble the capital letters F, E, I, and other designs. What these symbols signify is not known.

The cause of the abrupt change in culture between the Magdalenian and Azilian, which has been characterized as a revolution rather than a development, is explained on two theories. The discovery in the deposits of the epoch of skulls of two different types, one extremely long headed and the other extremely short headed, is considered to indicate the possibility that the Azilian culture was introduced by new races and was not a development from pre-existing European cultures. It is also suggested that the Azilians no longer lived in caves but in the open country and that, consequently, art practically disappeared. Moreover, the disappearance of the mammoth and reindeer from Central Europe cut off the supply of ivory and reindeer horns and man was forced to use the greatly inferior stag horns for making harpoons and tools. Azilian men, like their predecessors, knew nothing of pottery and they had no domesticated animals or plants.

The Azilian epoch seems to have occurred at the very close of the last Glacial Stage as is shown by the absence south of Belgium of the reindeer, arctic fox, and arctic hare. The common animals were those of the present day, such as wild boar, wild cattle, roe deer, rabbit, brown bear, and field mouse. The Azilian culture had a wide distribution in Europe and has been identified in Scotland, England, France, Germany, Austria, and Spain. The

Paleolithic is believed to have closed 7,000 to 10,000 years ago and was followed by the Neolithic period (q.v.).

HERDMAN F. CLELAND,

Professor of Geology, Williams College.

PALEOLOGUE, pa'lă'ô'log', Maurice, French diplomat and author: b. Paris, 1859. He was employed in various capacities in the Department of Foreign Affairs and was sent on diplomatic missions to Bulgaria, China, Korea and other countries. He has written several works mostly dealing with literature. They include 'L'art chinois' (1888); 'Vauvenargues' (1889); 'Alfred de Vigny' (1892; 3d ed., 1908); 'Profils de femmes' (1895); 'Sur les ruines' (1897); 'Le cilice' (1901); 'Rome, impressions d'histoire et d'art' (1902); 'La cravache' (1904); 'Le point d'honneur' (1907); 'Dante son caractère et son génie' (1909).

PALEOMASTODON, a genus of primitive elephants fossil in the lower Oligocene beds of the Fayoum, Egypt. The species varied in size from that of a tapir to that of a half-grown elephant and their frames and limbs were rather lightly built. The reduction of the dentition and certain other features point to still more primitive ancestors. The neck was relatively long, the skull long and narrow, having a high and crested occiput, and the front projecting into a long snout. Both jaws contained short, partly enameled tusks, those of the upper jaw curving downward somewhat divergently, and those of the lower jaw pointing straight forward.

PALEOMETEOROLOGY. See PALEOCLIMATOLOGY.

PALEONTOLOGY, the science of the ancient life that inhabited the earth during the vast periods of time which have antedated the age of man. This science dates back only to the beginning of the 19th century, when William Smith, Cuvier, Brongniart, Lamarck, Blumenbach and Schlotheim initiated the study of fossil life as a distinct branch of scientific research. It was christened "palæontology" by de Blainville and Fisher von Waldheim in 1834. Erroneous and fantastic ideas regarding the nature and origin of organic fossils had prevailed till the last decade of the 18th century, interesting accounts of which, as well as of the later history of the science, may be read in the

works of Zittel, Lyell, Marsh and Weller. Since the early days this science has made rapid progress until now its devotees are numerous, and they attempt to solve some of the most important problems bearing upon the origin and evolution of organisms, and upon the ancient life-history of the earth. The study of palæontology is carried on by means of fossils (q.v.) which, defined in the words of Zittel, are "all remains or traces of plants and animals which have lived before the beginning of the present geological period, and have been preserved in the rocks," and hence the successful pursuit of this science is in large degree dependent upon intimate knowledge of the closely allied sciences, geology and biology. This affiliation of palæontology to the two sciences mentioned is easily traced in the literature. The early works were descriptions of fossils, often arranged, as in Sowerby's 'Mineral Conchology,' 1812-45, without reference to their biological classification or to their relation as members of the fauna of a particular formation. In later works the tendency to diverge along two distinct lines is very apparent and at the present day we have two more or less widely separated schools of palæontologists: (1) those whose work is more intimately associated with that of the geologist; and (2) those who are essentially biologists. The former (stratigraphers, palæontologic geologists, geological biologists) are more interested in unraveling the relations of fossils to the rocks in which they are found entombed, in studying the order of succession, the evolution, the migration of fossil faunas in the stratified rocks, in developing the use of index fossils, that is, of particular genera and species of fossil plants and animals as indicators of particular geological formations; and, by the study of the geographic distribution of fossil faunas, in solving the problems of "facies development," and of palæogeography or ancient physical geography. The second group of palæontologists confine their attention almost wholly to description of the morphology, embryogeny, and phylogeny or genealogy of fossil organisms, and give only incidental notice to the geologic associations of the fossils they handle.

Palæontology has been of great aid to zoology and botany in clearing up mooted questions of classification, in explaining the origin of various obscure structures seen in modern plants and animals, and in adding to our knowledge of the determining factors of geographic distribution. The strictly utilitarian side of palæontology, involving the application of a knowledge of index fossils to determination of the proximity of beds of ore, coal or building stone, or to ascertainment of the depth of oil, gas or water-bearing strata, has not yet been accorded due recognition by those most interested in the exploitation of such economic materials, with the result that large sums of money have been expended in fruitless search for non-existent treasures.

The rocks of the earth's crust are classified according to their periods of origin into four great groups, each of which represents an era of immense duration, measured in millions of years. These eras are again divided into periods, represented by systems of rock formations, of which 13 are generally recognized, and the periods are again subdivided into epochs, ages, stages and episodes, each of these smaller

elements being represented by its corresponding rock-unit. With exception of the Archæan and Algonkian systems at the bottom of the scale, from which no satisfactory fossil remains have yet been obtained, each of the systems has been found to contain an assemblage of fossil organisms quite peculiar to itself, and not found in its entirety in any other system. This assemblage of fossil organisms in any system or in any geological formation constitutes its fossil fauna, which is an imperfect synopsis of the ancient life that formerly inhabited the vicinity of the ocean, lake or land basin in which the particular system or formation originated.

The faunas of two formations of consecutive age have as a rule many species in common, and on the other hand the faunas of two formations representing widely separated periods of time are found to be quite unlike, and to have few species and even few genera in common. The two extremes of such dissimilarity are naturally seen in the Cambrian and Pleistocene faunas at opposite ends of the geologic time-scale.

TABLE OF SYSTEMS, PERIODS AND EPOCHS, WITH DOMINANT TYPES OF LIFE.

Eras	Periods and Systems and Dominant Types	Epochs
Cenozoic Era of Vertebrates 3 million years	Quaternary (Man, Lamellibranchs)	Recent Pleistocene
	Tertiary (Mammals, Gastropoda, Insects, and land plants)	Pliocene Miocene Oligocene Eocene
Mesozoic Era of Reptiles 7 million years	Cretaceous (Pterodactyls, Dinosaurs, Echinoids)	Upper Lower
	Jurassic (Dinosaurs, Ammonites)	Upper Middle Lower
	Triassic (Amphibia, Ammonites)	Upper Middle Lower
	Permian * (Amphibia)	Upper Lower
	Carboniferous (Land plants, Crinoids)	Pennsylvanian (Coal measures) Mississippian (Subcarboniferous)
Paleozoic Era of Invertebrates 18 million years	Devonian (Fish, Goniatites, Corals)	Upper Middle Lower
	Silurian (Crinoids, Corals, Eurypterids)	Upper Middle Lower
	Ordovician (Graptolites, Orthoceratites, Trilobites)	Upper Middle Lower
	Cambrian (Trilobites)	Upper Middle Lower
	Algonkian	Life not well known
Proterozoic Time 2 years	Archæan	No evidence of life

* Sometimes given as a division of the Carboniferous.

While formations of different ages contain diverse faunas, it is found that a single formation presents essentially the same fauna in all

portions of its area of distribution, whence it follows that the fossil contents of a formation are, in general, characteristic of that formation, and that they serve as a means of identifying it in widely separated districts.

These general laws are subject to certain exceptions due to the influence of "facies development," the variations of faunal expression consequent upon changes in the physical conditions of life. These facial changes, when understood, assist rather than render more difficult the correlation of distant faunas, and their elucidation greatly aids the restoration of the ancient physiographic conditions.

Comparison of the successive fossil faunas with each other and with the modern fauna shows that there has been a slow but continuous progress in the expression of each fauna from that of Cambrian age with its unfamiliar lowly primitive types, to the highly organized animals and plants that form the dominant types of the modern fauna and flora. This progress is manifested in the successive members of the different races of animals that have descended from Cambrian ancestors, by their passing through a particular stage of evolution in each successive period, epoch and stage. Recognition of this stage of evolution enables the palæontologist to correlate entirely new faunas or species with the known faunas of standard sections or scales.

It must not be inferred that all races living at the present day have descended from Cambrian ancestors. Many of our well differentiated forms of modern life can be traced back only to the beginning of the Tertiary, or into the Mesozoic, or perhaps late Palæozoic, where they are represented by species whose distinguishing characteristics are less well developed so that they can scarcely be separated from contemporaneous ancestors of other races. Such early ancestral types which seem to possess in potential state the characters of two or more later descendant races are known as "generalized types."

There are also numerous groups of fossil organisms that appeared during early days, multiplied, attained their climax, during which they were for a time perhaps the dominant forms of land or sea, and then declined and eventually became totally extinct. Such extinct groups are eminently characteristic of the periods in which they lived.

Facies Development and Faunal Changes.

—Facies is the peculiar expression of the physical and faunistic characters of a formation at a particular point, and it is determined by the combination of climatic, physiographic, bathymetric and other conditions reacting upon the organisms of the neighborhood. Some formations, like the Devonian, present several varied facies in a limited area; others, like certain deep-water limestones of Ordovician and Carboniferous age, spread with scarcely any change over vast spaces. The chief types of facies are the littoral, coralline, sub-littoral or pelagic, abyssal, estuarine, fresh-water and terrestrial. The characteristics of each of these, with the organisms peculiar to it, are here passed in review.

A "littoral" facies is represented by deposits formed at the shore and in the shoal water contiguous to it. It comprises conglomerates, sandstones, shales and marls, and its organic con-

tents consist of the remains of animals and plants of beach and shallow water habits. Such are the heavy-shelled mollusks, notably those that feed on marine plants, also abundant worms, heavy-shelled crabs, acorn barnacles and hydroids. This facies is more common than any of the others, for the larger part of the sedimentary rocks have been made up of the products of continental erosion deposited near the coast.

Fossil coral reefs have been recognized in formations of nearly all ages and constitute a "coralline" facies. They are in all cases of shallow water origin, and their presence in ancient rocks has been generally accepted as evidence of the uniformly warm temperature of the seas in which they flourished. In the ancient reefs the coral structure has usually been obliterated by a metamorphic process called diagenesis, and the coral rock has become a dolomite. Such are the Guelph dolomites of the Silurian of New York and Ontario. Fossil coral reefs often afford faunas of many species and abundant individuals. The coralline facies of a formation is always associated, on its landward side, with a sparsely fossiliferous lagoon or saltmarsh phase, represented by red shales, containing gypsum and salt as in the Salina beds of New York, and on the seaward side by a series of highly fossiliferous beds, usually limestones or calcareous shales, which correspond to the deposits of the open ocean. These latter deposits usually abound in fossils of distinct pelagic type, such as cephalopods, brachiopods, sea-urchins, crinoids, crustaceans and thin-shelled mollusks.

"Sub-littoral" or "pelagic" facies comprise the deposits laid down in the deeper water of the continental shelf, and form an intermediate phase between the littoral and abyssal types. The rocks are mostly of organic origin (limestone and lime shales), with fine-grained sandstones and clay shales. As a rule they contain an abundance of well preserved fossils, including the remains of all kinds of animals that inhabit the open sea, together with some members of the littoral fauna. Deposits of this class, with their characteristic faunas, such as graptolite shales, ammonite and pteropod limestones, have often very wide distribution, and are hence of great value for determination of geologic horizons.

"Abyssal" facies is the type characteristic of the greatest depths of the ocean. It is represented in modern time by the foraminiferal and radiolarian oozes, and by green and red muds. It is recognized among ancient rocks by radiolarian cherts of Palæozoic and Jurassic age of Europe and Australia, by the chalk of Cretaceous age of Europe and North America, and by the Pliocene Barbados earth, which latter is evidence of upheaval of great ocean-depths in comparatively recent times.

The three remaining types of facies, "estuarine," "fresh-water," and "terrestrial," are associated with spread of continental conditions. The estuarine or brackish water facies presents lagoon, bayou and estuary deposits of sandstones, conglomerates and clay shales, sometimes alternating with limestones formed during temporary transgression of the ocean. The fossils of such deposits are species of animals that lived in brackish water, mingled with remains

of the fresh-water and land fauna and flora that were carried down by river waters and entombed in the estuarine deposits. The nodular shale of Carboniferous age at Mazon Creek, Ill., is a renowned example of this type of facies. Its varied fauna comprises amphibians, fish, clams, river-snails, land-snails, scorpions, spiders, myriopods, insects and crabs, together with abundant ferns.

"Fresh-water" and "lacustrine" facies are deposits formed in fresh-water swamps and lakes, important in the Devonian, Carboniferous, Jurassic and Tertiary systems. The Devonian deposits, known as Old Red Sandstone in Europe and as Catskill sandstone in the United States and Canada, consist mostly of red and gray sandstones and shales containing fish and plant remains. The swamp deposits of Carboniferous and later times are represented by beds of coal, lignite and clay shales, all containing abundant plant remains, and rarely relics of the insect, crustacean and vertebrate life. During the Cretaceous, Jurassic and Tertiary Periods, extensive lakes existed upon the several continents, and their sandstone, shales and limestone deposits have afforded hosts of vertebrate and vegetable remains, specially those of the Rocky Mountain region and Europe. Occasional beds of this facies abound in fresh-water snails and insects, as notably at Florissant, Colo. Angular breccias, conglomerates, sandstones, shales and clays comprise the deposits of the terrestrial facies, a type which has not yet been satisfactorily investigated in all its phases. The various deposits originated either as the residuals from denudation, or as flood-plain, desert and prairie deposits. They are important sources of fossils in some cases (flood-plain and prairie phases) but as a rule their mode of origin has not been conducive to preservation of organic remains.

All of these facies are being developed in different parts of the world at the present day, and geologists find that they have been developed more or less completely during all periods of geologic time. It is, however, worthy of note that the various marine facies greatly predominated in the older Palæozoic, that the estuarine and swamp conditions were markedly developed during Carboniferous time in most parts of the world when they were associated with a remarkable increase of swamp vegetation, and that the lacustrine or fresh-water deposits were prominent during the Devonian and again during the Tertiary Periods. Each of the above-mentioned types of facies has its peculiar faunal or floral aggregation of fossils, and study of these features of any formation enables the palæontologist to determine the distribution of the land and water bodies, and even to form some imperfect ideas regarding the nature of the climate, the topography of the land areas and the character and distribution of the fauna and flora of each successive epoch and episode of time.

Palæontology and Evolution.—The researches of palæontologists upon the order of succession of fossil organisms, and upon the various modes of development of certain types from their embryonic to their adult stages, have brought to light many facts supporting the doctrine of evolution, and have also demonstrated the origin and mode of evolution of many races

of living and extinct organisms. The results of these investigations along lines of profound interest may be found in the works of Beecher, Bernard, Clarke, Cope, Hyatt, Jackel, Jackson, Koken, Neumayr, Packard, Schuchert, Scott, Smith and Williams whose more important contributions are cited in the bibliography at the close of this article. See EVOLUTION.

Periods of Geologic Time and Their Faunas.—The following sketch of the series of extinct faunas that have succeeded each other as inhabitants of the waters and lands of the earth involves an elementary knowledge of the most important types of animals and plants. (See preceding Table of Systems, etc.) The history actually begins with the close of pre-Cambrian (Algonkian) time when the distribution of land and water was very different from what it is now. Regarding the life of the Archæan we know nothing and of that of the Algonkian very little. Many rocks of the latter system were originally of sedimentary origin, but they have been so thoroughly metamorphosed that few traces of their organic contents remain. The remnants discovered are of types similar to those of the succeeding Cambrian fauna, and include worms, linguloid brachiopods and crustacean remains. The extensive graphite deposits of the pre-Cambrian rocks are by some authors considered as evidence of original organic deposits.

Cambrian.—The Cambrian system is represented mostly by littoral and shoal-water deposits containing an abundant fauna, which, while of primitive type, is remarkable on account of its high degree of differentiation. Some of the Cambrian rocks, notably the calcareous shales, in regions of slight metamorphism (New Brunswick, Newfoundland and Scandinavia) abound in fossils. Elsewhere the sandstones, conglomerates and limestones are poor collecting grounds. This fauna, estimated to contain 1,000 species, comprises representatives of all the seven sub-kingdoms of invertebrate animals, and of 12 out of 30 classes. Vertebrate remains have not been found in Cambrian rocks. The entire fauna is marine, and the dominant types were trilobites, inarticulate brachiopods and shells usually referred to the pteropods. The trilobites form the most interesting elements of the fauna. Compared with those of later times they are more loosely built, and they present many features indicative of primitive types; characters which are seen only in the embryos of later forms. The brachiopods, of which 120 North American species are known, are almost entirely of the inarticulate type, with thin, rounded or spatulate, phosphatic shells, while there were a few members of the articulate group with transverse, calcareous shells. The hyolithoid shells, with triangular elongate form, are abundant. Sponges are recognized. The corals are doubtfully represented. The echinoderms are represented by a few rare cystoids. Among the gastropods there are coiled shells and limpet-like forms in the middle and upper horizons. The lamellibranchs have a single minute genus, and the cephalopods likewise one minute form. Worm trails and burrows are abundant and various forms of ostracods are found in the finer grained sediments. Radiolarians and foraminifera have been found, some of the

latter being indistinguishable from modern species. The only probable plant known is referred to the coralline algæ.

The Cambrian fauna in its entirety shows a very advanced stage in the differential evolution of organic types, and there is good reason to believe that long ancestral lines of fossil organisms originally existed in the pre-Cambrian sediments, and further to anticipate that continued search in the less metamorphosed deposits of that remote age will eventually bring to light some of those much sought for initial types.

Ordovician.—The fauna of the Ordovician, or age of graptolites, shows a marked advance in development of all its types over those of the Cambrian. It also shows a more distinct separation into facies, of which the pelagic, embracing orthoceratite, brachiopod and trilobite limestones and the graptolite shale facies are the more prominent. Most of the groups of animals which were initiated in the Cambrian, enjoyed a rapid evolution in the Ordovician time. During that period the trilobites attained their climax in respect of variety and numbers. The Ordovician trilobites present considerable advance over their Cambrian ancestors in respect of increased compactness of structure, perfection of the eye-structure and elevation of the visual surface above the head, whereby the efficiency of these organs must have been much increased. The cephalopods are represented by numerous orthoceratite genera, with straight or slightly curved shells, some of which were of great size, associated with closely coiled genera that resemble modern nautilus shells.

Among the brachiopods the inarticulate types, so common in the Cambrian fauna, occupy a subordinate place and are represented by numerous species. The articulate order attained so great an expansion that 325 species of North American Ordovician brachiopods are known. The Polyzoa appear first in the lower Ordovician and are abundant and varied in the upper zones. Gastropods are common. Lamellibranchs are common, with several genera of generalized type; corals of various types are common. The hydroid corals formed extensive reefs during Chazy and Trenton time. Echinoderms include abundant cystoids, several crinoids and rare starfishes. The cystoids are especially abundant in the lower Ordovician, where their fragmentary remains form solid limestone beds of several feet thickness. Sponges are common in a few localities and in the Trenton limestone of the Mississippi Valley is found the much discussed *Receptaculites*. A pelagic facies is recognized in the radiolarian cherts of Great Britain, France and Germany. The graptolite facies of the Ordovician, by some authors considered to be an abyssal facies, occurs in the form of gray and black bituminous shales and slates, in which numerous genera and species of graptolites are found arranged in definite zones that occupy the same relations to each other in widely separated parts of the world. This great dispersion and regular succession of genera and species render the graptolites the most important index fossils for the Ordovician, an advantage which is, however, somewhat negated by the difficulty attending their study. The group began in the upper Cambrian, attained wide distribution and various evolution during the Ordovician and

declined during the Silurian. These graptolite beds are well demarcated from the molluscan and brachiopod limestones and while they occur between the latter at various horizons throughout the general Ordovician and Silurian formation scales of Europe and America, they are best developed in basins where little of the other facies seem to have existed. The faunas of latest Ordovician time are known in only a few regions, since that period was one of comparatively sudden uplift of continental masses, accompanied in many parts of the earth by formation of mountains. But the few late remnant faunas that found shelter in protected basins present a transitional phase between the normal Ordovician and the succeeding Silurian faunas. Late Ordovician time is represented in most parts of North America by a marked hiatus of unconformity indicating wide land areas.

Silurian.—The earliest Silurian fauna of North America, that of the Clinton group, contains a few relics of the Ordovician fauna lingering on among a host of new species and genera, which were introduced with the return of marine conditions over the interior sea basin. The American rocks and faunas of Silurian time indicate: first, muddy waters of the Clinton epoch, followed by clear seas of Niagara time inhabited by a luxurious fauna, and in which pure organic limestones were deposited. Subsequently the shallow mediterranean Guelph Sea of America became dotted with extensive coral reefs, and toward the end of Silurian days the epicontinental seas were again largely drained to form lagoons, tidal mud-flats and salt lakes of Salina time. Then ensued a short period of wide land-emergence before the early Devonian transgression began. Facies development is well marked and it is worthy of note that the various facies occur in the same relative order and at equivalent horizons in widely separate regions; evidence that the causes which influenced their development in Silurian time acted simultaneously during successive epochs over the entire northern hemisphere. The mollusk-trilobite limestone of Niagara age in North America is duplicated by that of similar age in England (Wenlock), Sweden (Gotland) and central Europe (Bohemian). The Eurypterid fauna of the Salina group of New York is duplicated by the contemporaneous water-limestones of the English Ludlow and the Baltic Rotzkill beds. The coralline facies of the American Guelph is of the same age and character as that of the English Dudley, Swedish Gotland and Bohemian dolomites; and finally the Monograptus shales of Great Britain, Bohemia, Brittany, Scandinavia and New York are all of lowest Silurian age. Another interesting feature of the Silurian fauna is its division into two well-marked types—a northern or Baltic-British-American type and a southern Bohemian-Mediterranean phase, the species of which are quite distinct. All of the Silurian faunas of North and South America and of Asia are of the northern phase, and the Bohemian-Mediterranean type appears to be merely a local facies. It is of interest that the Silurian fauna of Australia contains representatives of both types.

The chief characteristic of the Silurian fauna is the great evolution of the crinoids, corals, the spire-bearing brachiopods and the

Eurypteridæ. Protozoa are rare; sponges and corals attain a remarkable variety and abundance, and in many districts the latter formed extensive reefs. The graptolites begin to decline. Cystoids take second rank after the crinoids, whose sudden expansion is expressed in the ratio of about 450 Silurian species to less than 50 from the Ordovician. The brachiopod fauna, while no larger, differs from that of the Ordovician in the increase of the spire-bearing types and in the remarkable development of intricate types with large solid shells. Lamellibranchs offer no important changes. Gastropods are numerous. Tentaculites, usually referred to the pteropods, occur by myriads associated with ostracods. The Silurian Cephalopods comprise straight-shelled *Orthoceras*, curved and turreted forms and coiled *Nautilus*.

The Arthropoda are represented by rare barnacles, numerous ostracods, some phyllocarida, rare scorpions, spiders and insects as well as by the trilobites and eurypterids. The trilobites show a slight decrease in numbers, but a greater diversity of form over their Ordovician ancestors. The water limestones (of mud-flat origin) of the Salina of New York and equivalent European deposits afford abundant remains of Eurypterids (q.v.), some of which grew to be six feet long. These creatures resemble in habits and structure the modern horseshoe crab (*Limulus*). Rare scorpions, spiders and insect remains have also been found in these uppermost Silurian lagoon deposits, and they show no very great differences from similar types of the Carboniferous. Their presence indicates the existence of terrestrial life on the extensive continental areas that emerged toward the end of Silurian time. In these highest Silurian rocks, specially in the Ludlow beds of England, Scotland and Podolia, are found the earliest remains of vertebrate animals in the shape of primitive fish-like creatures of the order Ostracodermi (q.v.).

Devonian.—The Devonian Period was one of constant local physiographic changes, and accordingly its formations and faunas present a greater variety of facies than is seen in any of the older Paleozoic systems. There are two prominent types of the Devonian, each with its distinctive fauna: (1) The marine deposits of limestones, marls, shales and sandstones; (2) the continental or terrestrial phase, known as the Old Red sandstone in Europe and as the Catskill shales and sandstones in the eastern United States and Canada. This twofold aspect of the deposits is more or less prominent in all the geological systems above the Devonian. The Devonian fauna as a whole is distinguished by the development of land vegetation, by rapid evolution of fishes, lamellibranchs and of goniatite cephalopods, and by the decline of trilobites and practical extinction of the graptolites and cystoids. Other groups expanded. Sponges comparable with the modern Venus-flower-basket, flourished in shallow seas; corals are abundant and formed reefs in many regions. The Hydrozoa are represented by numerous reef-building stromatoporas, and by straggling survivors of the graptolites. Among echinoderms the cystoids are rare; starfish and ophiurians occur commonly at a few localities, and the crinoids are the dominant types of this class, though not so abundant as in the Silurian. The blastoids are represented.

Worm-trails are common in the shales and sandstones of the middle and upper Devonian. A host of new brachiopods appears, while many Silurian genera run on. Lamellibranchs show a great advance over those of the Silurian, and in certain shale and sandstone formations they outnumber all other types of organisms. Gastropods of the family Capulidæ are abundant, and minute pteropod shells often form solid limestone beds. Among cephalopods a new type of closely coiled shells, *Goniatites*, with slashed sutures, appears in the lower Devonian, evolves rapidly and reaches its climax before the close of the period. An extinct group of crustaceans, the Phyllocarida, with long strong caudal spines, reach a considerable development, especially in the Hamilton epoch. Eurypterids are rare, though represented by the gigantic *Stylonurus* in the Catskill beds. The trilobites have many large and bizarre members, as well as a number of small, degenerate forms, during the early and middle Devonian, when they manifested a strong tendency to develop spines along the margin and on the surface of the carapace.

The Devonian is aptly termed the "age of fishes," for within its limits this class enjoyed a great expansion. The lowest Devonian fish fauna is like that of the upper Silurian with numerous Ostracoderms. This is succeeded by a fauna with a large number of acanthodian sharks, which are indicated by their spines. No remains of any vertebrates higher than fishes are known in the Devonian.

Plant remains in the form of marine algae are found throughout the Devonian. Some of these, like *Nematophyton* of gigantic size, were long supposed to be the trunks of coniferous trees. Others with delicately branching fucoid leaves are common, especially in the Hamilton, Portage and Chemung groups. The continental phase of the Devonian has afforded the earliest examples of land vegetation, all prophetic of the succeeding Carboniferous types. Both the fauna and flora of the upper Devonian show marked affinities by gradual transitions to those of the Subcarboniferous. See PALEOBOTANY.

Carboniferous.—The early part of the Carboniferous period was marked by a continued recession of the sea, which had begun in late Devonian time, and during the Carboniferous the land areas seem to have reached a greater expansion than they have at the present day. These Carboniferous land masses were of very different forms and situation from the present day continents. An Arctic continent occupied the greater part of the Arctic zone and extended by broad peninsulas southward toward the equator, over what are now eastern America, eastern Asia, central Europe and the eastern Atlantic Ocean. Another, Indo-African continent, covered that part of South America east of the Andes, extended across the south Atlantic, Africa, the Indian Ocean and Australia. An ocean spread over the present Pacific basin and also over Alaska, all of the United States west of the Mississippi River, Central America and the western part of South America, while a great mediterranean sea of irregular form encircled the globe and communicated at both ends with the Pacific Ocean. There was also a small Antarctic sea. Toward the close of Carboniferous time the ocean again transgressed and the land masses became for a time somewhat reduced in size. The Carboniferous

formations consequently present two well-marked facies: a marine facies with deposits of limestones and shales with mollusks, brachiopods, corals and foraminifera, more widely spread on the lower and upper Carboniferous; and a continental phase of sandstones, shales and coalbeds, holding abundant plants, and in some localities numerous insects, fish and amphibians. These facies as a rule occupy different basins, but occasionally they are found dovetailed into each other in such manner that their relative ages can easily be determined. The lands of Carboniferous time and especially the coastal swamps supported a dense and rank vegetation comprising more than 1,500 species of plants. Ferns, some of great size, were the most common type. Calamites with fluted many-branched stems and variform foliage, were giant predecessors of our modern horse-tail rushes (*Equisetum*). *Lepidodendron* and *Sigillaria*, related to clubmosses (*Lycopodium*), with trunks often five feet thick and 75 feet high; *Cordaites* with sword-shaped yucca-like leaves on a solid trunk 25 to 30 feet high; and other great tree-like plants intermediate in nature between the ferns and cycads, formed the bulk of the forest growth. In the shelter of these forests lived numerous insects, mostly primitive cockroaches, also dragon-flies, one of which had wings over 20 inches across; primitive forms of locusts, crickets, grasshoppers and also scorpions that were much like those of modern type. On the shores of the swamps lived large amphibious myriopods whose bodies were armed with branching spines. Some land snails like modern *Pupa* and *Zonites* have been found. The fresh-water facies also contain remains of lizard-like amphibians (*Stegocephalia*), many of which have been found in hollow *Sigillarian* stumps.

The marine phase of the Subcarboniferous contains the first abundant foraminiferan deposits. Minute *Endothyra* shells form the bulk of the Indiana oolitic limestone; *Fusulina*, like grains of wheat, and *Schwagerina*, a globular form, build great limestones in the upper Carboniferous. Corals are not so abundant as in the Devonian and coral reefs are rare. Crinoids were locally very abundant, especially in the Subcarboniferous beds at Burlington, Keokuk and Crawfordsville in the Mississippi Valley, where about 650 species have been found. The blastoids, with *Pentremites* as their most abundant type, attained their climax in the Subcarboniferous of America. Among the abundant bryozoa, one genus *Archimedes*, with its screw-like axis, is a good index fossil of the Subcarboniferous. Brachiopods were abundant as were also the Lemellibranchs. Gastropods present a number of heavy-shelled forms; among the Cephalopods, the orthoceratites have greatly declined; nautiloids abound, and the goniatites show great advancement over those of the Devonian, and toward the end of the period transitional types suggestive of the Triassic ammonites appeared.

The arthropod fauna of the Carboniferous is poor in trilobites, but eurypterids are common in some coal measure shales.

The Carboniferous vertebrate fauna is of interest by reason of the sudden expansion of amphibian types in the upper part of the system. The *Stegocephalia* (labyrinthodonts) are

represented by several genera, and consist of generalized types suggestive of the later crocodiles, lizards and snakes. The fish-fauna is abundant, comprising sharks and ganoids. The Waverly shales of Ohio have afforded numerous large lungfishes, and some fine examples of acanthodian sharks. Over 600 species of fish have been described from the Subcarboniferous limestones of America.

Permian.—During Permian time the continental conditions were even more prevalent than during the Carboniferous, and accordingly the marine phase is much restricted in distribution and its fauna diminished in numbers. Both plants and animals are transitional between those of the Carboniferous and Triassic. Many types characteristic of the Palæozoic have their last representatives, some of them, it is true, occurring abundantly, in the rocks of this system. *Productus*, *Orthoceras*, goniatites, trilobites and the fenestellid bryozoa, which latter formed extensive reefs in Europe, all become extinct with the close of the Permian. Other types, some of them initiated during the Carboniferous or earlier and continued into the Trias attain a considerable expansion, and give to the fauna a decided Mesozoic aspect. These are found among the lamellibranchs as well as among the ammonoids, fish and amphibians. The ammonoids attained a great expansion. The fish fauna of the Permian consists mainly of ganoids. Acanthodian sharks reached the climax of their evolution. The stegocephalian amphibians were varied and common, and were the dominant types of life. There were also snake-like members of this group, one of which was nearly 45 feet long. A new type of vertebrate appears in reptiles of land and fresh-water habits.

While the Permian flora is in general the same as that of the Carboniferous it contains some types not seen in the latter.

Mesozoic.—The Mesozoic fauna and flora are distinguished from those of the Palæozoic by the absence of trilobites, graptolites, orthoceratites, long-hinged brachiopods, tetracorallic and tabulate corals, cystoids, palæocrinoids, blastoids, eurypterids, goniatites, acanthodian sharks, and the great lycopods. On the other hand this era is marked by the introduction of numerous new types and by the expansion of many invertebrate groups, land and marine reptiles, multituberculate mammals, cycads and conifers. During the era a great change in the expression of the life is apparent, in that the early Triassic life presents close analogies with that of the late Permian, while during the era an almost complete change takes place, and that of the upper Mesozoic, especially the vegetation, affords considerable resemblance to the early Tertiary.

Triassic.—The wide extension of continental areas continued from Permian into Triassic time with perhaps a slight increase, and in North America marine Triassic fossils have been found in only a few places in the far West. The fauna as a whole is an impoverished one. The continental Trias, consisting of red beds in America, Europe and Asia, contains abundant remains of ganoid fish together with some cycads and conifers. In some regions these beds have afforded also numerous remains of often gigantic stegocephalian Amphibia, which attained their climax during this period. Small

amphibious precursors of the large marine Jurassic ichthyosaurs and plesiosaurs are found. The Theromorpha, reptiles exhibiting remarkable affinities with the carnivorous mammals, attained a great development in South Africa. The first turtles, crocodiles and dinosaurs occur here. The earliest mammalian remains consist of fragmentary jaws and multi-tuberculate teeth of small animals supposed to be allied to the modern monotremes.

The marine Trias is found well developed in the Alps with extensions into Asia Minor, India, Arctic regions, Pacific States and Australia. The number of species is comparatively small, though individuals are abundant. Foraminifera and calcareous sponges abound. Corals of perforate and aporose genera formed extensive reefs in some regions. Crinoids are represented. Sea-urchins were present. Among the brachiopods are a few remnants of Palæozoic genera, while new families are surprisingly developed. The lamellibranchs begin to show considerable expansion and the first true fresh-water unios appear here. The marine gastropod fauna is abundant, with some old types and others of later Cretaceous and Tertiary aspect. The ammonites, which began in the Permian, show a wide differentiation of form and complexity, and attain the culmination of their evolution in the upper Trias. Over 1,000 species have been described. Ostracods are abundant.

Jurassic.—The facies development of this system is very varied; the continental phase predominates in America as the Newark or Connecticut River sandstones, while the marine phase is most prominent in Europe and Asia. The Jurassic flora is quite similar to that of the Trias, made up of cycads and conifers which are forerunners of the recent pines. Among marine invertebrates the sponges and corals, largely of modern type, were so abundant as to form great reefs. Crinoids were abundant in individuals, though genera and species were few; echinoderms and Bryozoa were common, while the brachiopods were restricted to a few families. The lamellibranchs and gastropods include the first representatives of a number of modern families. The ammonites are by far the most abundant and characteristic forms of mollusks, and by means of them the marine Jurassic of Europe has been subdivided into some 15 zones, each characterized by its particular species. Belemnites, the solid cigar-shaped internal shell of squid-like cephalopods, are very abundant and varied, and the fossilized ink-bags of these creatures are common in some formations. The crustacean fauna shows a great increase of long-tailed decapods allied to prawns, shrimps and crayfish, and the earliest true crabs. Insects include dragon-flies, May-flies, termites, grasshoppers, crickets, walking-sticks and some beetles; also occasional bugs, flies and ants. The ganoids with heterocercal tails take a subordinate rôle while those with homocercal tails and scaly rhombic plates predominate. Sharks and rays and the first teleost, or modern bony fishes complete the Jurassic fish fauna.

The reptiles form the most interesting group of the Jurassic fauna, for during this period they reached the highest stage of their evolution both in variety and abundance. The Triassic stegocéphalians and Theromorpha give place to

the terrestrial dinosaurs and the marine ichthyosaurs and plesiosaurs. The latter held somewhat the same relation to reptiles that the whales of modern time hold to the mammals. Those sea lizards swarmed in the Jurassic seas where they preyed upon the fish. The dinosaurs held sway upon the land, not only during the Jurassic period, but also during the greater part of the succeeding Cretaceous. Another type of reptile prominent during Jurassic time and continued into the Cretaceous was the group Pterosauria or flying lizards, of which the pterodactyl is the best known example. Other types of reptiles, as turtles and crocodiles, are more or less common. At the same time when the reptilian stock developed flying creatures there appeared the earliest known bird. (See ARCHÆOPTERYX). The mammalian remains of Jurassic time are known only by isolated teeth and jaws of small size and very rare, and all are related to the marsupials and monotremes.

Cretaceous.—The flora of the lower Cretaceous is like that of the Jurassic, but gradually the cycads diminish in importance and a host of angiosperms appear, very similar to the trees and shrubs of to-day. Many genera of recent tropical and temperate zone plants occur in the Cretaceous rocks of Greenland and northern Europe, facts cited as evidence of the mild climate of those parts during Cretaceous time. The ammonites begin to decline and we see numerous degenerate types, last members of various races, with shells loosely coiled, turreted, hook-like, or even straight, many of which are characteristic index fossils. The group becomes entirely extinct with the close of the Cretaceous.

The close of Cretaceous time terminated the middle or Mesozoic period of the history of organic life and marked the extinction of a number of types of animals which had for long epochs dominated the lands and seas. This extinction is perhaps more evident here than at the end of the Palæozoic, and its causes are wholly unknown. It is true that some groups (Ammonites) had already begun to show marked degenerate tendencies attendant upon race senility, but the majority of the groups became extinct at the height of their evolution, when they were represented by their most highly specialized types. It is possible that this very specialization rendered them more liable to injury by slight though abrupt climatic changes or by sudden variations in the depth of the seas in which they lived. The great land and marine reptiles, the flying lizards, the mososaurs and toothed birds all became extinct. Likewise the ammonites and belemnites, so characteristic of the Mesozoic, have not been found above the upper limits of that system.

Cenozoic.—The life of this era is like that of recent time, particularly the marine life, for the terrestrial mammalian life of a large part of the system is very dissimilar to modern animals. The early classification of this system was based upon the increasing percentage of still living species found of both plants and animals fossil in the deposits. (See PALÆOBOTANY). Some of the distinctive types of invertebrates were of larger size than usual. Sponges and corals are abundant only in restricted localities. Foraminifera, Radiolaria, echinoderms, Bryozoa, lamellibranchs and gastropods are present in great variety while crinoids, brachiopods and cephalo-

pods are comparative rarities. The preponderance of crabs, with a number of extinct genera, over the long-tailed, lobster-like decapods is very marked. Acorn barnacles, often of large size, are common, and fresh-water snails and mussels, all of modern types, are abundant in the fresh-water deposits of both Europe and America. Insects of all kinds have been found in the Oligocene and Miocene deposits, especially at Florissant and White River, Colo., and in the amber of the Baltic provinces, which latter has furnished about 2,000 species.

But the greatest interest attaches to the vertebrate fauna of the Tertiary, for during the early days of this period the placental mammals outstripped the marsupials and monotremes and became the lords of the land, and toward the end of the period appeared man. The reptiles, which held so prominent a place during the Mesozoic, are reduced to the true lizards, snakes, crocodiles and turtles. The amphibia which, as Stegocephalia, had become almost extinct during the middle Mesozoic were resurrected in the Eocene as salamanders, toads and frogs, and continued thence till the present day. The fishes included numerous large sharks and a preponderance of bony fishes, of which many belonged to modern genera, such as perch, herring, carp, pike, catfish, eels, breams and mackerel. Birds exhibit a continuously expanding evolution during the Tertiary and they are still expanding. See MAMMALS; TERTIARY PERIOD.

Conclusion.—The dominant types of the consecutive periods present on the whole an increasing degree of perfection of structure, and the dominant types of one age are, as a rule, not related to the dominant types of the preceding age. These dominants are usually the most highly specialized members of the classes or orders to which they belong, and it is further to be noted that dominance and high specialization have in most cases been soon followed by decline and extinction. The small primitive forms of one period may evolve into the large dominant types of the next epoch and in their turn decline and disappear. In the invertebrates and lower vertebrates (fish, amphibia and reptiles) the rate of this evolution, and consequently the destiny of the race, is almost wholly dependent upon the presence and continuance of favorable conditions of existence, for these types have little or no ability to surmount physical difficulties. Among the higher vertebrates, enlargement of the brain mass and of the mental faculties enables the animals to circumvent unfavorable conditions to some extent, but they also are comparatively helpless. It is in man, with his highly-developed intellect and mechanical skill, that we see the only organism able not only to circumvent unfavorable conditions of life but actually to nullify them and to practically subjugate all other organisms or render them useful to him in his affairs. We have said that high specialization indicates approaching decline and extinction. That is true in respect of structural evolution, but as regards intellectual evolution, and the directions in which it may differentiate, we know next to nothing beyond the fact that intellectuality has up to the present time evolved with remarkable acceleration. In view of this it seems impossible to conceive otherwise than that man, under strong physical, moral and religious control, can have before

him any other than a future longer and more brilliant than his comparatively brief existence.

Bibliography.—The best accounts of the early history of the science of palæontology may be found in Lyell, 'Principles of Geology' (11th ed., Vol. I, New York 1872); Zittel, 'History of Geology and Palæontology' (New York 1901); Marsh, 'History and Methods of Palæontological Discovery' (New Haven 1879); Weller, 'A Century of Progress in Palæontology' (*Journal of Geology*, Vol. VII, 1899). For nature and mode of entombment and methods of collecting fossils, Geikie, 'Textbook of Geology' (4th ed., Vol. II, New York 1903); Schuchert, 'Directions for Collecting and Preserving Fossils' (Bulletin U. S. Nat. Museum, Vol. XXXIX, Washington 1895); White, C. A., 'Relations of Biology to Geological Investigation' (in Report U. S. Nat. Museum for 1892). For the general principles of palæontology, Chamberlin, 'A Systematic Source of Evolution of Provincial Faunas' (in *Journal of Geology*, Vol. VI, 1898); Clarke, 'Indigene and Alien Faunas of the New York Devonian' (in Bulletin 52, N. Y. State Museum, Albany 1902); Cope, 'Primary Factors of Organic Evolution' (Chicago 1896); Huxley, 'The Principles and Methods of Palæontology' (in Smithsonian Institution, Annual Report for 1869); Hyatt, 'Bioplastology and the Related Branches of Biologic Research' (in Proc. Boston Soc. Nat. History, Vol. XXVII, 1895); 'Cycle in the Life of the Individual (Ontogeny) and in the Evolution of the Group to which it Belongs (Phylogeny)' (in Proc. Amer. Acad. Arts and Sci., Vol. XXXII, 1897); Bernard, 'Principles of Palæontology' (in 48th Annual Report N. Y. State Museum, Vol. II, p. 131, 1897); Packard, 'A Half Century of Evolution with Special Reference to the Effect of Geological Changes on Animal Life' (in Proc. A. A. A. S., Vol. XLVII, 1898); Smith, J. P., papers (in *Journal of Geology*, Vols. III to VIII, 1895-1900); Williams, 'The Scope of Palæontology and Its Value to Geologists' (in Proc. A. A. A. Sci. Vol. 41, 1892); Williams, 'The Correlation of Geological Faunas' (Bulletin U. S. Geological Survey, No. 210, 1903). Among the systematic works are Woods, 'Palæontology, Invertebrate' (Cambridge Press, 3d ed., 1902), the only elementary work on this subject written in the English language; it is, however, devoted wholly to British fossils; Zittel-Eastman, 'Textbook of Palæontology' (New York 1900-02), a more technical, but thoroughly American work, the best for general purposes; Nicholson and Lydekker, 'Manual of Palæontology' (2d ed., Edinburgh 1889); and Woodward, 'Outlines of Vertebrate Palæontology' (Cambridge 1898), serve more special needs. The more valuable works of a stratigraphic nature are Dana's 'Manual of Geology' (4th ed., 1896); Geikie's 'Textbook of Geology' (4th ed., Vol. II, 1903); Kayser's 'Geologische Formationkunde' (2d ed., Vol. II, Stuttgart 1902); and Frech's 'Lethæa Geognostica' (3 parts, Stuttgart 1883-1903); Grabau, A. W., and Shimer, H. W., 'North American Index Fossils' (New York, 1910); Hutchinson, H. N., 'Extinct Monsters and Creatures of Other Days'; Lankester, E. R., 'Extinct Animals' (New York 1905); Lucas, F. A., 'Animals Before Man in North America' (New York 1902); Lucas, F. A.,

'Animals of the Past'; Lydekker, R., 'Geographical History of Mammals'; Nicholson, H. A., 'A Manual of Paleontology' (2d ed., Edinburgh 1879); Osborn, H. F., 'The Age of Mammals' (New York 1910); Scott, D. H., 'The Evolution of Plants'; Scott, D. H., 'Studies in Fossil Botany'; Scott, W. B., 'A History of Land Mammals in the Western Hemisphere' (New York 1913); Shimer, H. W., 'An Introduction to the Study of Fossils' (New York 1914); Williston, S. W., 'Water Reptiles of Past and Present'; Zittel, Karl A., von, 'Geschichte der Geologie und Paläontologie' (1899); Zittel, Karl A., von, 'Text Book of Paleontology' (trans by Eastman, London 1900). The last work has been completed to the Triassic only and discusses the successive faunas and formations of the Paleozoic in great detail.

GILBERT VAN INGEN,
Princeton University.

PALEOZOIC ERA, the second great division of geologic time and the first one in the sediments of which well-preserved organic remains have so far been found in abundance. It is preceded by the Proterozoic division and succeeded by the Mesozoic (mediæval life) and the Cenozoic (recent life) time divisions in ascending order. The name signifies ancient life and has reference to the character of the plant and animal life of the time, which was markedly unlike that of the present. As a time division, the Paleozoic is generally called an era, this term meeting with the recommendation of the International Geological Congress at its Bologna Convention in 1881. Dana in his 'Manual of Geology' (5th ed.), however, used the expression "Paleozoic Aeon or Paleozoic Time," and applies era to the next smaller subdivision. In this he has been followed by several authors. Though in its modern sense primarily used for a time division, the term Paleozoic is also applied to that division of the earth's crust which was formed during that time. And indeed this is the original use of the term, when it was coined for the reception of the fossiliferous rocks below the so-called Secondary or Mesozoic formations. The rocks thus named were formerly included with the crystalline rocks of all ages as "Primary," but later on they were separated at least in part, as "Transition rocks." Lyell, to avoid confusion, spoke of them as the "Primary fossiliferous rocks." The following parallel columns express perhaps as nearly as possible the correlation between the older and newer terms:

Older	Newer
Quaternary }	Cenozoic or Cainozoic
Tertiary }	
Secondary }	Mesozoic
Transition (or primary fossiliferous) }	Proterozoic
Primary }	

In the formation scale the term "group" was recommended by the International Congress as of co-ordinate in rank with that of era in the time scale. This recommendation has not been very generally adopted in America, where the term group is commonly used for a smaller formation. "Series" is sometimes used for such rock divisions as that corresponding to the Paleozoic Era but more commonly corresponds with epoch in rank.

The following subdivisions of the Paleozoic are recognized:

Carboniferous period and system.	Permian Epoch and series
	Pennsylvanian Epoch and series
	Mississippian Epoch and series
Devonian period and system	
Silurian period and system	
Ordovician period and system	
Cambrian period and system	

Characteristic Life of the Paleozoic.—The characteristics of Paleozoic life were very marked and stamp the Era as boldly contrasted with the succeeding Mesozoic. The Hydrozoa were represented by the group of Graptolites, wholly confined to the Paleozoic. Among corals the Tetracoralla (so-called from having four primary radiating lamellæ or septa with reference to which the others are arranged), the honey-comb corals, the tube corals, and the chain corals are characteristic types practically unknown in post-Paleozoic time. Among the Echinoderms, the two groups of Cystids and Blastids are wholly confined to the Paleozoic, while the Crinoids, or sea lilies, with few exceptions are likewise restricted to the Paleozoic. Star-fish, brittle stars and sea-urchins, while represented in Paleozoic rocks are more characteristically known from later strata. The Bryozoa, or sea moss, are well represented. These often constructed extensive reefs and in the Ordovician especially, gave rise to extensive deposits.

Brachiopods are perhaps the most important Paleozoic types, no less than 2,600 species having been described from the Ordovician and Silurian deposits alone. Several archaic families range from the Ordovician to the present time while modern types such as some of the Terebratuloid families begin in the middle or late Paleozoic. By far the largest number, however, end with the Carboniferous or before, while a few others run on past the close of the era.

Turning to the Pelecypods or bivalve mollusks, we find that their principal representatives belong to post-Paleozoic time. A primitive order represented by such modern types as the oyster and scallop (Pecten), alone has a prominent representation in the Paleozoic, where about 30 families are found. Of these more than one-half continued to exist beyond Paleozoic time, with few exceptions indeed down to the present time. Only 13 out of 40 families of this order (as now understood) are confined to the Paleozoic. On the other hand post-Paleozoic time is characterized by about 86 families. The gastropods are likewise essentially post-Paleozoic Mollusca, those of Paleozoic time being essentially primitive or archaic in character.

The cephalopods were well represented during the Paleozoic by the Nautiloidea. Of 40 families belonging to this class only three originated in post-Paleozoic time and only one of these, the family of the true Nautilus, continued to the present time. Of the 37 Paleozoic families three or four ran on past the end of the era. The straight-coned nautiloids, the bent cones and the loose-coiled cones are practically confined to the Paleozoic rocks, the close-coiled forms alone characterizing later horizons as well. The ammonoids on the other hand are

represented in Paleozoic rocks only by their more primitive types.

Among crustacea, the Trilobites are wholly confined to the Paleozoic rocks, of which they constitute in many respects the most characteristic type of fossil. Their greatest development was during Cambrian and Ordovician time. The remarkable order of Eurypterid crustaceans is also confined to the Paleozoic, constituting the most characteristic type of certain formations. The only other type of crustaceans abundantly represented in the Paleozoic rocks is that of the small bivalve ostracods.

Paleophysiography of North America.—The physiographic changes which the North American continent suffered during Paleozoic time may be summarized as follows: In early Cambrian time the greater part of the interior of North America was out of water, the eastern shore being probably a short distance east of the present Appalachians, and the western shore on the western flanks of the Rocky Mountains. The southern shore was not far north of the present southern boundary of the United States. A narrow gulf extended northward along the Appalachians, and probably connected with a similar gulf extending southward from the present Saint Lawrence Gulf. The land mass to the east of this trough has been called Old Appalachia and remained persistent throughout most of Paleozoic time. There is some reason to believe that a persistent trough also occupied the site of the Great Basin and that another persistent land mass lay to the west of that. The great interior, between these troughs, was land in early Cambrian, but gradually sank with many minor fluctuations, to a maximum submergence in mid-Ordovician. It was again widely emerged at the close of the Ordovician when the Taconic Revolution raised mountains in New England. A gradual re-submergence in Silurian times, re-established the sea. In mid-Silurian it extended north-westward over what is now Hudson Bay and the Arctic regions beyond. Near the close of the period, the sea became much restricted or wholly enclosed and highly saline. In this North American dead sea, the great Silurian salt and gypsum beds of New York, Ohio and Michigan were deposited. At the close of the Silurian nearly the whole of the North American continent became dry land and the sea was reduced to a narrow channel along its former eastern border. Toward mid-Devonian time this sea spread westward again to Michigan and southward to Indiana and the great Paleozoic coral reefs began to flourish. Many fluctuations and adjustments took place, the eastern border of the sea growing shallower and the western deeper. In early Carboniferous time, the sands deposited in the eastern part of this mediterranean sea permitted the existence of only a sparse fauna, while in the region now known as the Mississippi Valley, great reefs of crinoids flourished. In mid-Carboniferous time, the interior sea extended to the foot of the Rocky Mountains, while the greater part of the region east of the present Mississippi River was converted into the fresh water morasses, in which the extensive coal beds of eastern North America were deposited. This condition continued with slight changes through late

Carboniferous (Permian) time. At the same time western United States was the site of extensive enclosed seas, which under an arid climate gradually decreased in size, with the deposition of great beds of salt and gypsum. While this aridity existed in western United States and also in Germany, India, South Africa and Australia were colder than now and undergoing severe glaciation. The era was terminated by the great physiographic changes which accompanied the formation of the Appalachian Mountains and which has been called the Appalachian Revolution. This resulted in the permanent elevation of much of the North American continent. Marine deposits of the early Mesozoic are known only in the north-west, west and southwest. Later in Cretaceous time, the Great Plains region and the Atlantic border were resubmerged, but eastern North American remained continuously above water, with the exception of a slight submergence in the Hudson and Champlain valleys in late Pleistocene time.

CHARLES LAURENCE DAKE,
*Associate Professor of Geology and Mineralogy,
School of Mines and Metallurgy, University
of Missouri.*

PALERMO, pā-lēr'mō, Italy (1) a seaport town, capital of Sicily, beautifully situated on the northern shore of the island on the Gulf of Palermo, surrounded by a fertile plain and partly enclosed by lofty hills. Its numerous spires, domes and towers give it a very imposing appearance when approached from the sea. Two main streets, the Via Vittorio Emanuele and Via Maqueda, intersect the city at right angles to each other. Near the centre is an octagonal space, the Quattro Canti, lined with elegant buildings in different styles of Grecian architecture and adorned with numerous statues. The two principal streets are opened into by a great number of others, mostly narrower and of an inferior description; but all well paved with blocks of lava. There is now an extensive system of electric tramways. Admirable places of resort are provided by the Marina and the Flora—the former a superb terrace about 80 yards wide, stretching about a mile along the bay; the latter, commencing in the east where the terrace terminates in a magnificent public garden regularly and beautifully laid out, and adorned with statues, fountains and rustic temples. Here is also a botanic garden of some extent, and there are several other public gardens. The public edifices are numerous, but do not in general display much taste. The most important are the cathedral, the church of San Giuseppe, the church of San Salvatore, La Martorana, and other churches; the royal palace, finely situated and surrounded by beautiful gardens, a large and irregular pile of buildings, among which the only great attractions are the chapel of King Roger (or Palatine Chapel), rich in mosaics, "perhaps the most beautiful palace-chapel in the world," and the observatory; the archiepiscopal palace; the national museum and picture-gallery; the communal library, with about 220,000 volumes; the national library, with over 150,000 volumes; the university, attended by 1,200 students; the barracks, arsenal, courts of justice, theatres, hospitals and several literary and charitable endowments. Palermo has a good roadstead and harbor, which has

been recently improved, and a well-equipped shipbuilding yard and dry dock have been constructed. The principal articles of export are sumach, wines, oranges and lemons, sulphur, tartar, olive-oil, citrate of lime, tomatoes, tomato paste, asphalt, hides, dried vegetables, macaroni, etc.; and among the imports are coal, grain, wood, petroleum, tobacco, iron and steel rails, sheets, bars, etc., cement, machinery, sulphates, fish, etc. The total number of vessels that cleared from the port in 1900 was 3,732, with a tonnage of 1,677,234. The manufactures of the town include gloves, marble works, etc., and there is a foundry. The fisheries on the coast are productive, and give employment to numerous hands. Palermo is the see of an archbishop, and the seat of a supreme court with jurisdiction over the whole island; of a criminal court for the province; of a commercial and several other inferior courts, and of several important public offices. Its foundation is attributed to the Phœnicians. From them it passed to the Carthaginians, who made it the capital of their Sicilian possessions and the centre of an external commerce. The Romans obtained possession of it in 254 B.C., made it a free town, and conferred upon it many important privileges, in consequence of which it increased rapidly and became very prosperous. After the fall of the Roman empire it remained, except for a brief vandal-rule, a part of the Eastern empire, till in 835 the Saracens became its masters, and kept possession of it till 1071, when it was taken by Roger the Norman, who founded the kingdom of Sicily. Since then it has always continued to be the capital. It has repeatedly suffered from earthquakes. This and the other vicissitudes which it has undergone is probably the reason why so few remains to antiquity are to be found within it. Some, however, still exist in its environs, which, both on this account and their own intrinsic beauty, are in many respects more attractive than the town. During an insurrection which took place in January 1848, the town was bombarded; and Garibaldi seized it in 1860. Pop. about 325,000. (2) The province has an area of 1,948 square miles. Its coast consists of a series of extensive bays and bold promontories. Its interior toward the south is traversed, east to west, by a branch of the Neptunian Mountains. The streams are numerous, but small. The soil is fertile. Pop. about 300,000.

PALES, *pālēs*, in ancient Italy, a divinity who presided over fields and meadows, and was worshipped sometimes as a god, sometimes as a goddess, in which latter character Pales was identified with Vesta or Anna Perenna. The festival of *Parilia* or *Palilia* was celebrated 21 April, the anniversary of the founding of Rome, when milk and cakes of millet were offered. Shepherds begged forgiveness for any trespass their flocks might have made on sacred places, and prayers were made for the prosperity of the flocks. Cognate with Pales are "*palatium*," a palace, and "*Palatinus*," one of the seven hills of Rome, and this divinity, as protector of property and home, is among the earliest figures that occur in Roman mythology.

PALESTINE, also called **THE HOLY LAND**, **CANAAN**, **JUDEA**, and **THE LAND OF ISRAEL**, a classic region southwest of Syria. Its western shore forms the east-

ward boundary of the Mediterranean Sea and its north, east and south boundaries, respectively, are the Mountains of Lebanon, the Arabian Desert and Arabia Petraea. It is situated between lat. 31° 30' and 33° 30' N.; long. 34° 30' to 36° E.; has a length north to south of about 110 miles, a breadth of 50 to 60 miles, and an area of about 10,000 square miles.

Topography and Physical Features.—The surface generally is mountainous, traversed by branches from the chain of Lebanon, one of which stretches south in a direction nearly parallel to the coast of the Mediterranean, forming the watershed between its basin and that of the Dead Sea; while another, turning more to the east, stretches along the left side of the valley of the Jordan. The mountains attain their greatest height, of about 9,100 feet, in Mount Hermon, where they first become detached from the principal chain. None of the other heights exceed 4,000 feet; but many are celebrated from the frequent mention made of them in the Bible, and from the events of which they have been the theatre. The most remarkable are Carmel, forming a promontory in the Mediterranean, on the southwest side of the Bay of Acre; Tabor, or the modern Jebel Tur, at the northeast extremity of the plain of Esdraelon; Ebal and Gerizim, in the valley of Samaria; Gilead and Nebo, or Pisgah, on the east side of the Jordan; and Zion, Moriah, and the Mount of Olives, in and near Jerusalem.

Of limestone formation, the mountains abound in caves of all varieties of size and form, many of them of Scriptural importance. The earliest mention of a cave in Scripture is in the history of Lot (Gen. xix, 30). The next is at the death of Sarah, when Abraham bought the cave Machpelah for a burying-place. This is now contained within the limits of a mosque, at Hebron, and remains in all probability just as it was when the patriarchs were buried in it. The Moslems can give no real information regarding it, for they will not enter it, dreading immediate death at the hand of Abraham's spirit, which they believe to reside in it. Caves are frequently mentioned in the books of Judges, Joshua and Samuel, but the only one specified is that of Adullam, which has been identified with the cave of Khureitûn (the ancient Hareth), some five miles south of Bethlehem—a singular cave, or rather series of caves and chambers, extending for miles, to which the one entrance is an orifice not larger than a door, half-way down the almost perpendicular face of a precipice; this orifice is reached by a shelf or ledge of rock, along which one has to find the way cautiously to the cave. The interior is quite a labyrinth, with vaulted chambers remarkably dry and warm, but with no impure air. It could accommodate hundreds of men, all hidden in these far-extending chambers. There are caves at Deir-Dubban, not far from Khureitûn, about half-way between Jerusalem and Eleutheropolis, but these do not correspond with the scenes in David's history; although these western ones are reputed to be David's cave, and the eastern (Khureitûn), near Tekoah, Saul's caves or cave. That these huge caves or grottoes at Deir-Dubban were used both for hiding-places and dwelling-places, both in Jewish and Christian days, is quite evident; but whether this is the place of the Adullam

cave of David is not so plain. There were caves in Galilee also. The "cotton cave," or "Kotton-Megharah," under Jerusalem, is a wonderful cavity, extending under a large portion of the city. But though called a "Megharah," it is an old quarry, out of which Jerusalem was partly built, and therefore interesting, especially as the traces of the quarrymen are still visible in every recess.

Palestine has comparatively few plains, but has numerous valleys; it is the country which Moses describes, "a land of hills and valleys." The small plains are numerous, the large few; among them are the maritime plains of Phœnicia and Philistia, the river plain of Jordan, the inland plain of Esdraelon, and the mountain plain of the Bekâ, between the two Lebanons. These are widely different from each other, though within a small territory. The sea plain from Gaza to Beirût are well peopled and tilled. The Jordan plain is nearly a waste of sand, that river making no further impression upon the levels on each side than merely to fringe itself for some 20 yards with verdure. The Esdraelon plain, or "valley of Jezreel," is a fine plain of considerable extent, fertile and well cultivated. In the district of El Huleh or "the Waters of Merom," and in such low-lying districts as Merj-Sanur, between Samaria and Jenin, are marshes and at certain seasons wide tracts rendered almost impassable by the overflow of streams. The heat during the greater part of the year, from April to November, dries up most of the marshes and scorches both hill and plain. In later ages this is more especially true, as formerly the extensive woods, orchards, vineyards and olive-yards which clothed the country shut out the heat, cooled the soil, and retained the moisture.

Hydrography.—In Palestine from time immemorial, wells and springs have been held in such veneration, that it is as much sacrilege to destroy a well as to defile a mosque or injure a tomb. The places named from the En spring (or fountain) and the Beer (well), are very numerous. Among these are "the Fountain of Two Calves," En-Eglaim, near the Dead Sea; the "Fountain of Gardens," En-gannim, of which name there were two cities, one in Judah and another in Issachar; the "Fountain of the Goat," Engadi, now Ain Jiddi, on the shore of the Dead Sea, one of Judah's rocky springs; the "Fountain of Sharpness," or Swiftmess, En-Haddah, one of the springs of Issachar's plains; En-Rimmon, in the southern extremity of the land; the "Fountain of the Fuller," En-Rogel, the spring of Jerusalem, known in early ages, etc. Besides these there were many other fountains all over the land. There was Hagar's "Fountain" or "Well," Beer-la-hai-roi, in the southern desert, near Beersheba; the "Fountain in Jezreel," by which Israel pitched in the battle between them and the Philistines; and others. There are the "wells" of the patriarchs in different places—the Well of Abraham at Beersheba, now represented by two, still well filled and surrounded by large stone troughs; the wells of Isaac, south of Gerar, Sitnah, Esek and Rehoboth, of which only the last can be said to have a representative, at Ruhaiben on the great Roman road; the Well of Jacob, dug out of a spur of Gerizim, and close by Joseph's tomb; the Well of Bethlehem, which David knew so well as no doubt the well of his shepherd-boy-

hood; the Well of Sirah near Hebron, where Abner was overtaken by Joab's messengers. There are a good many modern wells in use, which, though probably the remains of ancient ones, are unmentioned in Scripture. Few of these wells are properly kept, though none are gratuitously destroyed. Some have become quite unserviceable; and even Jacob's Well is in such a state of disrepair (the masonry in the upper part having fallen in) as to require almost a redigging before it can be of use. Elisha's Fountain still pours out its clear current though little care is apparently bestowed on it.

There is but one river worthy of the name in Palestine—the Jordan, one of the most tortuous of streams: always supplied with water, though often so considerably beneath the verge of its banks as to be invisible from any distance. The Jordan originates in streams that come from Lebanon and Hermon, and unite in the Waters of Merom. It falls into the Dead Sea after a course of about 70 miles direct, or 200 including windings. Numerous streams find their way westward to the Mediterranean from Libanus and its prolongations or offshoots as far as the Hills of Judah. Equally numerous streams flow eastward from the same range into the Huleh, Sea of Galilee, Dead Sea and Jordan. Antilibanus, sending its offshoots down the east of Jordan and forming the mountains of Golan, Gilead, Ammon and Moab, is the watershed for a large tract of country between itself and the Ghor or Jordan Valley. Though the rivers are in general small, yet they are not mere summer brooks as many suppose. That but few of the innumerable wadis or water-courses are filled throughout the year is true; but still there are several permanent streams which do good service in the districts through which they pass. Passing by what we may call "Lebanon streams," which are always vigorous, there is the Zerka, a few miles north of Casarea; the Aujeh, a little north of Jaffa, and the Rubin, a little south of this last town; and the Mukutta or Kishon (Kutta-Kishon), which is sometimes, however, low enough, so low that when it reaches the sea it is lost in the sands. None of these are navigable, but they are rivers all the year round, and wide enough to allow boats to ply on them for some little distance. There is a vast number of water-courses in every part of the land, which would make its irrigation minute and complete were the rain sufficient to fill these, or rather sufficiently regulated and distributed over the year to keep these always filled; and were the land property covered and its soil protected by wood, so as to moderate the heat and prevent the excessive evaporation. The words of Moses were true words when he called it "a good land, a land of brooks of water, of fountains and depths that spring out of valleys and hills." The whole land bears marks of having been better watered than at present, and contains everywhere the remains of artificial appliances, such as terraces, cisterns and wells, by which the rain was regulated and distributed.

The lakes of Palestine are three in number, Merom Tiberias and the Dead Sea, the first seven feet above, the last 1,250 below sea-level. For quiet beauty the Huleh, or "Waters of Merom," with the adjoining vale, are remarkable, and for subdued attractiveness the Sea of Tiberias; but for brilliance there is nothing to

PALESTINE

Scene on the Jordan River

PALESTINE

Court of Antonio, Jerusalem

be compared to the Dead Sea—the ancient Asphaltis. Whatever of tameness there may be about the former two, about this last all is grandeur, notwithstanding the aridity of its shores, and the discomforts of its exceptionally hot climate. The silvery sparkle of its waters arising from their saline and bituminous composition gives a brightness to the scene which is enhanced, not neutralized, by the dark shadows of the Mountains of Moab. These lakes form three singular depressions or troughs in the great natural groove or gorge extending from the Bekâ to the Arabah, about 200 miles. This extraordinary hollow, so far below sea-level, is kept in its present state mainly by its own heat. Were the climate to become temperate, the Sea of Tiberias would rise greatly and transform the Jordan into a Rhine, in parts of the Ghor into a lake; the Dead Sea would swell up and overflow into the Arabah, producing changes in the whole of the southern region which it is impossible to calculate upon. The length of the Dead Sea is 45 miles; its greatest breadth 12. The density of its waters varies between 1,160 and 1,230 (pure water being 1,000). There are ancient shore-lines at a height of 1,200 feet on the surrounding hills.

Geology.—From the southern border of Palestine, where the hill-country of Judah begins, to the extreme north, there is almost unvarying limestone. In passing from Sardinia, Italy, Greece or Asia Minor there is an interesting resemblance, in color, feature and composition, between the rocks of these regions and those of Syria. Syria is, as a whole, a rugged, hilly region composed of limestone of the Secondary period; a country seamed and torn by volcanic action from one end to another; long stripes of depression and ridges of upheaval running parallel; the latter broken across and across into wide districts of tableland interspersed with hollows and valleys, with solitary hills or little groups of clustering peaks. The great masses of rock which constitute the mountains of Palestine and Lebanon are Jura limestone; compact, hard, not rich in fossils, and full of caverns and grottoes. This rock is everywhere the basis on which have been deposited in some parts extensive tracts of volcanic products; as also chalk and chalky limestone, magnesian limestone (dolomite), sandstone, conglomerate, marl, etc. On the west of the Jordan and Arabah the chalk formation which prevails through the southern desert terminates with the desert; and the Jura limestone, beginning with the mountains south of Hebron, holds its course northward, forming the mass of the western hill-country of Carmel and of Lebanon. East of the Jordan and Arabah, where, around Petra, large masses of porphyry, sandstone and limestone lie in close proximity, the same Jura limestone extends northward through the Belkah and the mountains of Ajlûn; and is likewise the basis on which rest the vast volcanic tracts of Haurân, Jaulân and Lejah.

Flora and Fauna.—The flora of Palestine is large and varied; about 1,000 species have been noticed and the whole number is probably at least 2,000. Among the trees are the cedar, oak, ash, olive, palm, sycamore, oleander, walnut, etc. Wheat, barley and other grains are cultivated; the vine is almost neglected now,

save in the colonies, some of which have had great success with the orange crop.

The number of mammals inhabiting Palestine is large for the extent of the country, amounting to about 80 in number. Of the wild animals mentioned in the Bible the lion and the *reem* or unicorn, that is, the aurochs, are no longer found in Palestine. Among carnivorous animals are the wolf, the hyæna, the jackal, the leopard, on the sides of Carmel and Gilead or in the forests of Galilee; and the bear, in Hermon and Lebanon. The wild boar is common and much dreaded by the husbandmen on account of the ravages it commits. Other mammalia are the wild goat, the gazelle, the coney, hare, jerboa, rat, mouse, bat, etc. Of the birds of Palestine there are over 350 species; chief among them are the roller, bee-eater, hoopoe, Smyrna kingfisher, belted kingfisher, sun-bird, great shrike and bulbul. More noticeable than these brightly-clothed birds is the immense number and variety of the larger birds of prey—the vultures, eagles, falcons, griffons, kites, peregrines and buzzards, which abound in every part of the Holy Land, and are at first sight its ornithological characteristic. Reptiles are numerous. They include the land and the water tortoise, the crocodile (leviathan), the chameleon and a variety of lizards and serpents. Fishes are abundant in the Jordan and its affluents, and in the Sea of Galilee are found in immense shoals. The most numerous species are the barbel and the bream. Lower in the scale of animals are the scorpion, the locust, hornet, bee and grasshopper.

History.—The name Palestine, derived from the Hebrew *Pelescheth*, and meaning the land of the Philistines, occurs in this sense in several passages of the authorized version of the Bible, and in several others in the Hebrew, where it is translated *Philistia*. It is properly applicable only to the southwest part of the country, stretching along the shores of the Mediterranean. It appears to have been first used in its more extended sense by Greek authors, and derived additional currency from its adoption by Josephus and Philo. The ancient name of the country was Canaan, which it evidently owed to the descent of its inhabitants from Canaan, the fourth son of Ham, and a grandson of Noah. When thus named, in the time of the patriarchs, it was parceled out among a number of independent tribes or nations; the Kenites, Kenizzites and Kadmonites, on the east of the Jordan; the Hittites, Perizzites, Jebusites and Amorites, in the hill-country of the south; the Canaanites proper, in the centre, from the Jordan to the coast; the Girgashites, on the east shore of the Lake of Tiberias; the Hivites, in the north, among the ramifications of Lebanon; the Philistines on the south, and the Phœnicians on the north coast. In the time of Moses the country east of the Jordan was conquered and divided among the tribes of Reuben and Gad and the half tribe of Manasseh. Under Joshua the work of conquest was carried on to the west of the Jordan; and the whole territory, though not to the extent originally promised, allotted to the remaining half tribe of Manasseh and the other 10 tribes (1445 B.C.); the larger portion of the south falling to the tribes of Judah and Benjamin. Under Solomon the work of conquest appears to have been completed, and all the

land which was originally promised was included within the limits of his kingdom. Under his son Rehoboam the kingdom was rent in twain, and subdivided into the separate kingdoms of Judah in the south and Israel in the north. (975 B.C.). The latter kingdom was often designated by the name of Samaria, its capital. The division of the country into tribes was completely broken up by the Captivity, which carried away 10 of them to Assyria and supplied their place by a new colony; and by the subsequent transportation of the remaining tribes of Judah and Benjamin to Babylon. (584 B.C.). After the destruction of the Babylonian Empire Palestine fell under the dominion first of the Persians and then of the Macedonians. When Palestine became the cradle of Christianity with the birth of Jesus Christ, the Romans had established their ascendancy and divided the region into four provinces of Galilee in the north, Samaria in the centre, Judea in the south and Perea, which included all the country east of the Jordan. Under Constantine Palestine, now regarded as the Holy Land, acquired new interest and recovered in some degree from the calamities by which it had been laid desolate; and in 396 A.D., on the division of the empire by Theodosius and the formation of two empires, a western and an eastern. Palestine became a province of the latter. This was its condition at the time when Islamism began to make its conquests. Palestine, unable to offer any resistance, soon fell a prey; and Omar, in 636, after taking possession of its capital, converted it into one of the provinces of his caliphate. The severities exercised toward the Christians having roused the indignation of Europe, gave rise to the Crusades, and Jerusalem became for a time the capital of a Christian kingdom. Ultimately, however, Mohammedanism prevailed, and Palestine sunk into a degraded state; from which it is only now recovering. It is only within the latter half of the 19th century that the exploration of Palestine was first carried out systematically. The most valuable results have been those achieved under the direction of the "Palestine Exploration Fund," a society organized in 1865 for the purpose of making an exhaustive exploration and an exact survey of the Holy Land. The triangulation of western Palestine was begun in 1871 and finished in 1877. A large and detailed map of the country has been published and an immense mass of valuable information regarding topography, natural history, its interesting ruins, archaeological remains and holy places, etc., accumulated. A German society for the exploration of Palestine has existed since 1877. The present population of the country is estimated at 650,000, the Arab element being the prevailing one, and the Arabic language generally in use; fully 125,000 being Jews, whose numbers have increased through the Zionist movement. (See ZIONISM). The people consist partly of the fellahin or settled cultivators, artisans, etc., partly of the nomad Bedouin, who live by rearing cattle or by less reputable means. The country exports some grain, olive-oil, oranges, etc. Jaffa, Haifa and Acre are the chief ports, Jerusalem and Nablus the largest towns. Chapels and monasteries belonging to Greek Orthodox, Roman Catholic and various Protestant churches abound

throughout the land, and especially on and near the sites where the principal events connected with New Testament history were enacted. A feature of interest is the great amount of property acquired by the sultan since 1885 in the Jordan Valley and other places, and administered on progressive agricultural principles.

The Nineteenth Century and After.—To get a comprehensive outlook on affairs in Palestine during this period and to gauge the sentiment of its population to-day and of the scattered children of Israel who look upon it as their national home, it is necessary to glance backward through the ages to the year 134, when Hadrian took Jerusalem, suppressed Bar Cochba's revolt in blood and expelled all Jews from Judæa, and trace the many, if feeble efforts of the oppressed people to regain their ancient heritage. A few from time to time migrated to the Holy Land, but the country offered few attractions for traders and artisans. In the 13th and 14th centuries the Mongol and Tartar invasions wrought havoc in the Near East, and Palestine was laid waste with such barbaric thoroughness that it never entirely recovered. The early Turkish sultans were well disposed toward the Jews, as the caliphs had been before them, and granted asylum to the refugees from the Spanish Inquisition. Later sultans were not inimical, even if not friendly disposed, and little waves of immigration from Poland, Russia, Austria and Moldavia arrived at intervals. Napoleon, with his far-seeing instinct, proposed to found a Jewish state in Palestine during the siege of Acre, but his proposal was coldly received in Jewry and was abandoned. A few thousand Jews, virtually all immigrants or the descendants of immigrants, eked out a wretched existence in the decayed towns of Palestine. They were supported to a large extent by the "Chalukah," or charitable funds to which the Jews of Europe contributed, nominally for the support of poor scholars studying in the Holy Places. The revival of Palestine as a Jewish land may be said to date from about 1840, when Mehemet Ali's claim to Syria directed attention to that part of the Turkish dominions. Lord Palmerston, who had saved the Sultan from his Egyptian vassal, compelled the Turks to protect the Jews from the Druses and the Syrians, and instructed the British consul at Jerusalem to watch over the interests of all Jews. The first Anglican bishop of Jerusalem, appointed in 1841, was a converted Jew. At the same time Sir Moses Montefiore and M. Crémieux, in an unofficial Jewish mission, reawakened the interest of their co-religionists in Palestine as a country to which the persecuted Jews might go. Several small colonies were actually founded, and the Jewish population of the towns began to increase rapidly. The Jews of western Europe and America took little interest in the subject until it was forced upon them by the Russian "pogroms" in 1881-82. Many of the refugees went to the Holy Land, and with help from the West, formed the Jewish colonies which, until the outbreak of the War of 1914, were prosperous. The political side of the movement is generally known under the name of Zionism (q.v.). The settlers suffered by the fall of Abdul Hamid,

for the Young Turks made it clear from the outset that they would abolish all special privileges to alien races, and would compel, for example, Christians and Jews to serve in the army. At the outbreak of the war in 1914 there were 125,000 Jews in Palestine, half of whom lived in Jerusalem. All that was needed to assure the growth of Palestine was an honest and benevolent administration, but this the Young Turks could not or would not provide. The course of the war, however, has considerably altered the prospects of Palestine. The British Palestine campaign was prosecuted with great vigor in the closing months of 1917 under General Allenby. On 31 October Beersheba was captured and Gaza was reached on 7 November. The next part of the advance was comparatively simple across the plain of Philistia. The junction of the railway between Jerusalem and Damascus was seized, and Joppa was taken on 17 November. Very difficult country was entered, however, when the British troops climbed into the limestone hills of Judæa. Turkish attacks were incessant; Allenby attacked the Turks northwest of Jerusalem so hotly that they were obliged to draw reinforcements from their lines south of Jerusalem. This made the road from Beersheba, south of Jerusalem, much easier. On 7 December Allenby, again driving from the south, took Hebron, and moved swiftly on Bethlehem, occupying the Jericho road east of Jerusalem. Simultaneously the troops to the northwest virtually joined hands with this force and reached the Schechem road, which runs out of Jerusalem to the north. Jerusalem was completely isolated and the surrender was made without a single shot having been fired into the city, or even into its outskirts. The capture of the capital thus effected, the troops gradually pushed northward, relieving the country, it is to be hoped for all time, of the Turkish usurper. The British occupation means that Moslem, Jew and Christian will receive impartial justice in a land sacred to all. Immediately the proposal for the establishment of a Jewish state in Palestine was touted everywhere, meeting with general favor among the several sections of Jewry. The British government, after a long and careful examination of the scheme, promised to use their best endeavors to carry it out. A large and thriving Jewish settlement in Palestine, under the supervision of Great Britain, or her Allies, would make for progress in the Near East and would thus accord with British policy. It would serve also as a rallying-point for Jews all over the world, and it would confer a benefit also on the Christian and the Moslem worlds, which are equally interested in the Holy Land and its undying religious memories.

Present Political Status.—The British Military Administration was in control of Palestine from the conquest in 1917-18 to 1 July 1920, when a civil administration was set up with Sir Herbert L. Samuel as High Commissioner. In the peace settlement with Turkey, the latter renounced her sovereignty over Palestine and in 1920 the mandate for Palestine was entrusted to Great Britain. An object of the mandate was the establishing of a national homeland for the Jewish people in accordance with the Balfour Declaration of 1917. The High Commissioner until 1922 was aided by an Advisory Council;

composed of the heads of the chief government departments and ten unofficial members, four of whom are Moslems, three Jews and three Christians, who represent the several communities. A new constitution was promulgated 1 Sept. 1922 providing for a high commissioner and commander in chief and an executive council. A Legislative Council replaces the Advisory Council and is empowered to pass ordinances for the government of the country.

Recent Internal Progress.—The opening of a modern school in Jerusalem in 1856 by Elise von Herz-Lämel of Vienna, the founding in 1870 of the Agricultural School at Jaffa by the Alliance Israélite Universelle, and the attempt in 1878, which failed, to establish an agricultural settlement at Petah Tikvah in Judea by Jews from Jerusalem, were the beginnings of a new era for Palestine, which led to more extended colonization in the '80s after the Russian pogroms and after 1897 when the Zionist movement was organized by Herzl at Basle. The promotion of agriculture and handicraft has been affected naturally by the war, but the upward movement continues, with growth in population and resources to which all parts of the Jewish world contribute, chiefly, of course, Russian Jewry at home or in lands to which it may have emigrated. Without accepting the preferred statement of enthusiasts, there can be no doubt that under efficient administration and trained leaders, with diversified crops, the avoidance of needless charity to individuals, and through knowledge of land laws, rural Palestine may witness a new era. The salutary influence of the Anglo-Palestine Bank has already been proved, and the Jewish labor problem will present fewer difficulties in time. Farm schools, reforestation stations, an agricultural college and an agricultural station, with farms and nursery, have all come into life. The urban development, with 85,000 out of the 100,000 Jews living in 12 cities, offers as serious problems but these will be overcome if present plans are realized. The Tel-Abib Jewish suburb shut off from traffic from Friday sundown to Saturday sundown, with its streets lined with trees, its ample water supply, square-set concrete houses, surrounded by gardens, and 20 minutes by bus from Jaffa, which has there many of its public buildings, is an example of what can be done on modern lines in education, trade and industry. Miss Henrietta Szold has written at length on this subject in the 'American Jewish Year Book for 1915-16' (Philadelphia Jewish Publication Society).

T., 'The Immovable East Studies of the People and Customs of Palestine' (London 1913); Huntington, H., 'Palestine and its Transformation' (London 1911); Leach, C., 'The Romance of the Holy Land' (London 1911); Lees, G. R., 'Village Life in Palestine' (London 1905); Sidebotham, H., 'England and Palestine' (London 1918).

See BETHLEHEM; CRUSADES; JERUSALEM; JEWS; NAZARETH; other localities mentioned; and for *Bibliography*, SYRIA; PALESTINE EXPLORATION FUND.

PALESTINE, Tex., city, county-seat of Anderson County; on the International and Great Northern and the Texas State railroads, about 130 miles north of Houston. It was set-

tled in 1846, and was chartered as a city in 1846, receiving a new charter in 1905. It is in an agricultural region in which cotton is one of the principal products. In the vicinity are salt mines and deposits of iron ore. The chief manufactures are cotton products, iron products and packed-beef. There is considerable trade in grain, cotton, fruit and vegetables. The prominent buildings are the railroad offices and shops, the Y. M. C. A. building, the churches and schools. A point of interest is Fort Hous-ton, a stockade for protection against the Indians in the early days. The government has been of the commission form since 1909. Pop. (1920) 11,039.

PALESTINE EXPLORATION FUND, founded 1864, and incorporated as a society in London, 22 June 1865, for the purpose of systematic and accurate investigation of the Holy Land for biblical verification and illustration. Work began in 1865-66 to determine sites for investigation and to collect information; it was continued from 1867-70 to verify the holy sites; from 1872-77 to survey western Palestine; 1873-74 for archaeological research; 1876 to explore the desert of the Tih; 1881 for the survey of eastern Palestine. In 1881 an ordnance survey map of the country was published with descriptive volumes on the topography, physiography, archaeology, and other details. Notwithstanding opposition from Turkish authorities in 1882, since then the Dead Sea region and the Wady Arabah have been surveyed; the buried cities in the Tell el Hesay mound have been excavated; also sections of the south and southwestern portion of Jerusalem; and excavations have been carried on at Gath, Gezer, Beth-Shemesh and other localities. The survey of southern Palestine began in 1914 under Captain Newcombe and Messrs. Wooley and Lawrence; operations were naturally suspended during the World War 1914-18, and the fighting in this region which ended in the occupation of Palestine by the British. A *Quarterly Statement* since 1869 and an *Annual* since 1911 are issued by the society, which also maintains an interesting "Palestinian Museum" at its headquarters in London.

Following the British example German, Austrian, French and American explorations have been carried on. The "Deutscher Palästina-Verein," founded in 1878, made notable surveys east of the Jordan and excavations at Megiddo; Austrian work was accomplished at Jericho and Taanach; French work in Petra, Moab, Edom and eastern Palestine. An American archaeological educational institution is maintained at Jerusalem where also is established the well-known Dominican biblical and archaeological school.

Among important publications issued by the British Palestine Exploration Fund are 'Survey of Western Palestine: Memoirs' (7 vols., 1881-86); Conder, 'Survey of Eastern Palestine' (1889); Clermont-Ganneau, 'Archaeological Researches' (2 vols., 1896, 1899); Bliss and Dickie, 'Excavations, 1894-97' (1898); Bliss and Macalister, 'Excavations in Palestine, 1898-1900' (1902); Peters and Thiersch, 'Painted Tombs in the Necropolis of Marissa' (1905); Macalister, 'The Excavation of Gezer' (3 vols., 1912). Consult also Besant, W., ed., 'Thirty Years' Work in the Holy Land,' an

official summary of the society's work (London 1895); Conder, 'Palestine' (in 'The World's Great Explorers and Explorations,' London 1889). For French work consult *Revue biblique* from 1892; *Revue de l'Orient Latin* from 1893; for German work, *Zeitschrift des deutscher Palästina-Vereins* from 1878.

PALESTINE PILGRIMS' TEXT SOCIETY, a society founded in London in the early '80s with the object of collecting, translating and publishing the early descriptions of Palestine written by pilgrims between the early Christian centuries and the 16th. The originals were written in Arabic, Hebrew, Greek, Latin, Old French, German and Russian during a period covering about 13 centuries. Among the most celebrated of these are Saint Jerome's 'Pilgrimage of the Holy Paula' (382 A.D.) and Bohaeddin's 'Life of Saladin' (1145-1232). Within 12 years after its foundation the society had completed its original program, having published 14 volumes and a general index (1887-97). The handling of the volumes has been turned over to the Palestine Exploration Fund.

PALESTRINA, pā-lēs-trē'nā, Giovanni Pierluigi, (or Pietro Aloisio), Da, Italian composer and reformer of ecclesiastical music: b. Palestrina (ancient Praeneste) 1526 (Haber), or 1514 (others); d. 2 Feb. 1594. He probably studied in the school of music of Gaudio Mell, and in 1551 was appointed by Pope Julius III, master of a choir of boys in the Julian Chapel, Rome, and was the first to receive the title of chapel-master. In 1554 he published a collection of masses dedicated to Pope Julius, who admitted him into the college of choristers of the Pope's Chapel. He was soon appointed chapel-master of Saint John Lateran, and six years later to the same post in Santa Maria Maggiore, in which he continued till 1571. About 1562 the Council of Trent, on reassembling, had taken up, among other subjects, the abuses which had gradually sprung up in church music and which had grown to an intolerable degree. Not only were masses founded on profane airs, often of the most frivolous kind, but the composers of the day, as their manuscripts show, not content with working upon popular airs which suggested the most unbecoming associations, actually imported the words of the profane melodies into their scores. The work of reform was entrusted to the Pope Pius IV, who appointed a commission to inquire into and regulate the matter. As there was no music in existence such as the commission required, however, and Palestrina, almost the only composer from whose works some illustrative fragments could be drawn, was assigned the task of showing that the recommendations of the commission were as consistent with art as with religious usage. In fulfilment of this important task he composed three masses for six voices, which by their artistic beauty and profound devotional feeling at once settled the question beyond dispute. One of them in particular, the 'Missa Papæ Marcelli,' so called in gratitude to his patron, at once established for him a position in the highest rank of musical genius, a place to which the subsequent advance of musical science has only confirmed his claim. In reward for this great achievement of his,

Palestrina was appointed in 1571 chapel-master of the Capella Giulia and musical director to the Congregation of the Oratory of Philip Neri. He also became teacher of the musical school founded by Nanini. He likewise undertook the revision of the chants of the Missal and the Breviary. A complete edition of his works was published by Breitkopf and Hartel (1885-93). The music of Palestrina is written in mediæval Church modes and is lacking in emotional expression. It is, however, noble and majestic and well suited for the expression of religious sentiment. Consult Cametti, 'Cenni Biografici di Giovanni Pierluigi da Palestrina' (1895), and the older work of Baini (1828).

PALESTRINA, Italy, a town in the province of and 23 miles east-southeast of Rome. It stands upon the slope of a hill and commands a magnificent view. It was a place of Greek origin, and had become important long before Rome existed. Known under the Roman Empire as Præneste it attained great magnificence, and was often the residence of the emperors. It has numerous ancient remains, particularly those of an immense Temple of Fortune, but the only modern building of note is the Barberini Palace. Pop. 7,000.

PALEY, pā'li, William, English divine and philosopher: b. Peterborough, July 1743; d. Bishop-Wearmouth, 25 May 1805. He was educated at Cambridge, and in 1766 became a fellow and tutor of Christ's College. In 1767 he was ordained a priest. He held the tutorship of his college for about 10 years, and his lectures during this period, which were highly successful, contained the elements of his future works. In 1776 he married and gave up his fellowship. Law, bishop of Carlisle, had already presented him with the living of Musgrave in Westmoreland, to which he retired; and he afterward received two other small livings. In 1780 he became prebendary of Carlisle, and in 1785 chancellor of the diocese. In 1794 he was made prebendary of Saint Paul's, and in 1795 sub-dean of Lincoln. His principal works are 'The Principle of Moral and Political Philosophy' (1785); 'Horæ Paulinæ' (1790); 'View of the Evidences of Christianity' (1794); 'Natural Theology, or Evidences of the Existence and Attributes of the Deity collected from the Appearances of Nature' (1802). As a writer Paley was distinguished by clearness and cogency of reasoning, force of illustration, and lucidity of arrangement. He had little claim to originality, and acknowledged in a general way his indebtedness to others and particularly to Tucker; but what he borrowed he generally set in a clearer light, and developed with the practical sagacity and strong common-sense which characterize the best English writers. In his 'Moral and Political Philosophy' he follows the principles of Locke. He rejected the theory of a moral sense invented by Hutcheson to save the morality of the school of Locke, and founded his system purely on utilitarianism. His views may be summed up in his own words: Christian virtue is "the doing good to mankind, in obedience to the will of God, and for the sake of everlasting happiness." The idea of the 'Horæ Paulinæ,' long considered his most original work, is said to have been suggested by Doddridge. The 'Evidences of Christianity' is mainly founded on

Lardner's 'Credibility of the Gospel History,' while Butler and others contributed to its completeness, and much of the argument of his 'Natural Theology' has been shown to be taken, without direct acknowledgment, from a work of Bernard Nieuwentyt, a Dutch philosopher of the previous century (1654-1718), on the 'Right Use of Contemplating the Works of the Creator,' an English translation of which appeared in 1718-19. The celebrated illustration of the watch is taken almost literally from Nieuwentyt. However, Paley made no claim for originality in anything but the presentation of his views, so he cannot be charged with plagiarism. His 'Evidences' and 'Natural Theology' are devoted to an attempt to prove the existence of God by the argument from design. Consult Albee, E., 'A history of English utilitarianism' (New York 1902); biographies of Paley by Meadley (1809); Edmund Paley (1824); and Lynam (1825); Stephen, 'History of English Thought in the 18th Century' (New York 1881).

PALFREY, pāl'fri, Francis Winthrop, American lawyer and soldier, son of J. G. Palfrey (q.v.): b. Boston, Mass., 11 April 1831; d. there, 5 Dec. 1889. He was graduated from Harvard in 1851, was commissioned a lieutenant-colonel in the Civil War and served with gallantry. He resigned in 1863 owing to a severe wound and in 1865 was brevetted brigadier-general of volunteers. From 1872 he was register in bankruptcy. He wrote 'A Memoir of William F. Bartlett' (1879); 'Antietam and Fredericksburg' (in 'Campaigns of the Civil War' series 1882), etc.

PALFREY, John Gorham, American historian and Unitarian clergyman: b. Boston, Mass., 2 May 1796; d. Cambridge, Mass., 26 April 1881. He was graduated from Harvard University in 1815, studied theology, and in 1818 accepted the pastorate of the Brattle Street Congregational-Unitarian Church, Boston, succeeding Edward Everett. He resigned in 1830 to accept the chair of sacred literature at Harvard where he remained until 1839, during which period he was dean of the faculty and one of the three preachers at the university chapel. In 1835-43 he was editor of the *North American Review* and early allied himself with the anti-slavery movement; he delivered a course of lectures at Lowell Institute, Boston, in 1839 and in 1842, and in the latter year was elected to the Massachusetts legislature where he served until 1843. In 1844-48 he was secretary of the commonwealth of Massachusetts, and in 1847-49 served in Congress; from 1861-67 was postmaster at Boston and subsequently acted as United States delegate to the Anti-slavery Congress in Paris. He wrote much and forcibly in opposition to the slave power, was an editor of the *Commonwealth* in 1851 and contributed to the Boston *Whig* a series of articles, 'The Progress of the Slave Power,' which attracted much attention. He allied himself with the Free-soil party and was their candidate for governor in 1851. Among his publications are 'Evidences of Christianity' (1843); 'The Relation Between Judaism and Christianity' (1854); 'A History of New England from the Discovery by Europeans to the Revolution of the 17th Century' (1866), etc. The last is his greatest work and a supplement-

tary volume was added by his son F. W. Palfrey (q.v.), 'The History of New England from the Revolution of the 17th Century to the Revolution of the 18th Century' (1890).

PALGHAT, pāl-gāt', India, town in Malabar district, Madras, 74 miles east of Bepur, and a station on the Madras Railway. It does a flourishing business with the western coast, has a Swiss Protestant missionary station, libraries, reading-rooms, schools and Victoria Jubilee College. Captured by the English in 1768 it served as a base of operations against Tippoo Sahib. Pop. about 50,000.

PALGRAVE, pāl'grāv, Sir Francis, English historian: b. London, July 1788; d. Hampstead, 6 July 1861. He was son of a Jewish stockbroker; was carefully educated at home; wrote a French version of the Homeric 'Batrachomyomachia' at eight; studied law; was married and became a Christian in 1823, when he changed his name from Cohen to Palgrave, his mother's maiden name. He practised principally in pedigree cases, devoting himself to antiquarian studies; contributed largely to the *Quarterly and Edinburgh reviews*; edited for the Crown 'Parliamentary Writs,' 'Rotuli Curiae Regis,' 'Kalendars of the Treasury of the Exchequer,' and 'Documents and Records Illustrating the History of Scotland'; and wrote 'History of England' (1831, only one volume), 'The Rise and Progress of the English Commonwealth' (1832); 'Truths and Fictions of the Middle Ages: the Merchant and the Friar' (1837); 'The Lord and the Vassal' (1844), and 'The History of Normandy and England' (1851-64). He was knighted in 1832. His work, though faulty in some details, did much to revive popular and critical interest in the Middle Ages.

PALGRAVE, Francis Turner, English poet and critic, son of Sir Francis Palgrave (q.v.): b. Great Yarmouth, 28 Sept. 1824; d. 24 Oct. 1897. He was educated at Charterhouse and Oxford, becoming fellow of Exeter College in 1846. He was employed in the education office after acting as Gladstone's private secretary for a time, and 1850-55 was vice-principal of Kneller Hall, a normal college at Twickenham. He became a friend of Tennyson with whom he passed many summers in Europe, and in 1884 resigned from the education office, in which he had risen to the post of assistant secretary. In the following year he succeeded his old friend John Campbell Shairp as professor of poetry at Oxford. He was a man of remarkable sweetness of character, sensitive and cultured; his book, 'The Passionate Pilgrim' (1858), is a spiritual autobiography, which also gives some light on the facts of his life. He is best known as the critical editor of 'The Golden Treasury' of English lyrics (1861; 2d series 1896), the first volume of which ranks as a classic anthology. He edited several other volumes of selections, from Shakespeare (1865), of hymns (1867), of 'Stories for Children' (1868), of lyrics (1871), from Herrick (1877), from Tennyson (1885), etc., and wrote 'Visions of England' (1881), and 'Amenophis' (1892).

PALGRAVE, William Gifford, English diplomat and Orientalist, son of Sir Francis Palgrave (q.v.): b. Westminster, 24 Jan. 1826; d. Montevideo, 30 Sept. 1888. He was edu-

cated at Oxford; went to India immediately after graduation; and entered the Bombay native infantry, which he soon left to become a member of the Society of Jesus and to undertake missionary work in southern India. In 1853 he went to Syria as a Jesuit missionary. He narrowly escaped death in the Damascus massacre of June 1861, being saved only by his perfect coolness and his wonderful knowledge of native dialects and customs. In England, Ireland and France he attempted to rouse indignation at the Syrian massacres. Napoleon III became interested in him, and in 1862 sent him across central Arabia to learn the feeling of the Arabs toward France,—an adventurous journey described in Palgrave's 'Narrative of a Year's Journey through Central and Eastern Arabia' (1865). He decided that there was no chance for Christian missions in Arabia, left (with the consent of his superiors) the Society of Jesus and entered the English diplomatic service. He was sent to Abyssinia in 1865, was British consul in Trebizond 1867, in Saint Thomas 1873, in Manila 1876, in Bulgaria 1878, and in Siam 1879, and in 1884 became minister to Uruguay. He wrote 'Herman Agha,' an Eastern romance (1872); 'Essays on Eastern Questions' (1872); 'Ulysses: Scenes and Studies in Many Lands' (1887), and 'A Vision of Life' (1891), a mystical poem, published posthumously.

PĀLI LANGUAGE AND LITERATURE.

—The Pāli is the tongue used in intercourse between the people of culture in the north of India for about 1,000 years from B.C. 700 on. It was owing to this medium of mental interchange that such far-reaching reform movements as Buddhism and Jainism became possible at all in the then totally disrupted condition of the country as a whole. Pāli is the idiom employed in all the earliest inscriptions in India, and had great influence in further developing the languages spoken in India. The canonical books of early Buddhism were written in Pāli, about B.C. 450-250, and in the commentaries on them. In these ancient writings the text itself is referred to as Pāli. The etymological derivation of this word seems plain. It means "rule, canon, a series of canons." Pali, in fact, was generally used by the Buddhists for the space of more than 1,000 years, and is still so used for sacred purposes in Siam, Ceylon and Burma. The first Pāli book published by an Englishman was 'Mahā Vamsa of Ceylon,' by George Turnour in 1837, he being then colonial secretary in Ceylon. An anthology of canonical verses, edited by Prof. Fausbøll in 1855, also appeared. A very good dictionary of Pāli, by R. C. Childers (1872-75) was published. In 1882 the Pāli Text Society undertook the collection and revised publications of the canonical texts.

There were two underlying causes which made Pāli one of the great literary vehicles of the world. The political cause was the establishment of the great state of Kosala and Magadha, right in the heart of the settled Aryan part of India, along about B.C. 650, leading irresistibly to a new standard speech, instead of the hitherto scattered dialects of the group of small commonwealths that had used indiscriminately vernaculars that bore to Vedic Sanskrit about the same relation as did the

different forms of speech in Italy to the Roman one, the Latin. When, therefore, Pāli was adopted at the court of Kosala, at Sāvatti, this fact led to a crystallization and concentration of language for that whole region (about the size of England and Scotland combined) and the surrounding country. And when Gautama Buddha (q.v.), himself a native of Kosala, decided on employing Pāli in his teaching and propaganda work, there was made as important a step forward in the direction of literary unity as was the case when Luther's translation of the Bible in the Middle High German of his time inevitably helped that dialect to the supremacy it has enjoyed in Germany ever since. Later, too, Buddha's disciples likewise compiled the scriptures of their new creed in Pāli, and this form of the native idioms thus became paramount for a long time.

James Prinsep devoted his rare genius to the decipherment of the Pāli inscriptions of northern India, notably those of King Asoka. It was largely due to his labors that Pāli became generally recognized by Western science as the literary tongue *par excellence* of India. How Pāli, however, first originated is still an unsolved riddle. No pre-Buddhistic documents couched in it have so far been discovered.

Professor Franke indeed has shown in his admirable researches and acute deductions that Pāli was a form of Sanskrit retaining much of the earlier forms and grammatical intricacies of Sanskrit which were lost in the later development of that tongue. He also has demonstrated that the type of Pāli employed in the first Buddhistic writings was that of the Avanti district and of its capital, Ujjeni, a celebrated seat of pre-Buddhistic civilization. Mahindā, the disciple who took the Buddhistic texts to Ceylon, was a native of the Avanti country and presumably taught in Pāli. The earliest canonical texts collected so far may be divided into three classes, or *prithakas* (literally, "baskets"), namely, the *Suttas* (doctrine), the *Vinaya* (rules), and the *Abhidhamma* (analytical exercises). Most of the earlier Pāli writings of the order have come down to us in about the same shape in which they were resolved upon and later promulgated by the Council of Vesālī, a century after Buddha's death. It is pretty evident that some of these early books were lost in India, however.

Of other literary works in Pāli, subsequent to the Buddha canon, three only seem to have survived. These are the 'Melindha-penha,' edited by V. Trenckner and translated by Rhys Davids under the caption of 'Questions of King Milinda,' a charming book, a religious romance; then the 'Netti Pakarāṇa,' edited by E. Hardy, and the 'Petāka Upadēsa.' There are, however, still extant in Burma a number of other Pāli books by unknown authors. In fact, Burma seems to be a treasure-trove in Pāli, as yet quite insufficiently explored. In its many Buddhistic convents there, it is known in a general way, there are hidden away rare manuscripts in Pāli. It is also surmised that Tibet, the west of China adjoining and, possibly, Japan may also hold surprises of the kind in store for the scientific world.

WOLF VON SCHIERBRAND,

Author of 'America, Asia and the Pacific'; 'Germany: the Welding of a World Power'; etc.

PALIMPSEST (Greek *palin*, back, again, *psestos*, rubbed), a written page prepared by erasure for being filled with new matter. Both the Greeks and Romans erased manuscripts for the purpose of again using the parchment. Cicero banters his friend the lawyer Trebatius upon his economy in using palimpsests in his correspondence, and expresses the hope that it is his own consultations and not Cicero's letters that he erases. No ancient palimpsests have come down to us. Probably the use of them by the Greeks and Romans was attended with no disadvantage to literature. When, however, the Greek and Roman commonwealths had been overthrown, and almost all the ancient manuscripts preserved in Europe were in the monasteries, the use of palimpsests began to prevail in the Middle Ages. It is still a matter of controversy whether literature has gained or suffered by the practice. On the one hand, it is held that but for the value of their material, the scraps of ancient manuscripts which have come down to us in the form of palimpsests would have been lost. On the other, it is believed that valuable manuscripts have in this way been ruthlessly destroyed.

It was in the 7th century, when Caliph Omar had cut off the supply of papyrus furnished by Egypt, that a great deficiency of parchment was felt. This deficiency continued until the invention of paper. The use of palimpsests increased until the 11th century, when it reached its height. Some declare that nearly the whole of ancient literature was thus lost in the 8th century. From the time of the Renaissance this practice was discountenanced; it was forbidden by edicts, but it did not entirely cease until the introduction of printing. In the East the use of palimpsests began much later, and never became so general as in the West. The scarcity of parchment was increased by the demand for legal documents. The monasteries of Bobbio, Fulda, Saint Gall and Mainz were among the most extensive manufacturers of palimpsests. That which replaced the ancient manuscripts was writing of an ecclesiastical character, lives of the saints and copies of the church services.

At the Renaissance attempts were made to decipher the ancient and underlying writing on palimpsests, but it was not till the 18th century that any progress was made. Knittel (1761) deciphered fragments of a Bible of Ulphilas, and Bruno discovered some entirely new fragments of Livy and Cicero. Niebuhr and others made subsequent discoveries, and the subject was taken up systematically and pursued with great success by Angelo Mai (q.v.), librarian successively of the Ambrosian and Vatican libraries.

The processes employed in deciphering palimpsests vary according to the nature of the manuscripts. Those which have been scraped and rubbed with pumice-stone and afterward bleached are nearly indecipherable. Those which have been merely washed with lime-water and dried are revived by chemical processes. Various recipes which have been found successful are used successively till the right one is found. The result of the researches made is on the whole disappointing, because the monks only made use of imperfect copies and fragments of ancient writings for their palimpsests, and carried on the re-manufacture of clean parchments wholesale, mixing up various manuscripts cutting them into fresh shapes, and thus obliterating forever the connection of the original works. A very large proportion of the discoveries thus made are fragmentary, but many of the fragments are of great value. Among most remarkable discoveries of palimpsests in recent times is that of the Syriac version of the four Gospels by Mrs. Agnes Smith Lewis (q.v.) in Saint Catherine's Monastery, Mount Sinai (1895).

PALINDROME, the name given to any verse or line which reads the same either forward or backward; for example that which is put in the mouth of Satan—*Signa te, signa, temere me tangis et angis* (cross thyself, cross thyself, you touch and torment me in vain), or as "Madam I'm Adam."

PALINGENESIS. See RECAPITULATION.

PALINURO, pǎ-lē-noo'rō, **Cape**, Italy, promontory in southern Italy, jutting into the Tyrrhenian Sea, northeast of the Gulf of Policastro; in classical times Palinurum Promontorium, and now sometimes called Cape Spartimento. The end of the cape forms a rocky and dangerous peninsula, on which Roman fleets were wrecked B.C. 253 and 36. The name is Greek and is the origin (not the outcome) of the story of the death and burial of Æneas' pilot, Palinurus.

PALISADE CELLS AND PARENCHYMA, elongated cylindrical cells standing upright between the surface layer of the upper side of a leaf (q.v.) and the thicker layer of loose assimilation cells forming the under side. The palisade cells characterize the "palisade parenchyma," which gives strength to the leaf and contains most of its chlorophyll.

PALISADES, The, a rocky cliff on the right bank of the Hudson River (q.v.), extending from Fort Lee, N. J., to the hills of Rockland County, N. Y., a distance of about 15 miles. They are of basaltic trap rock, a formation which was intruded between layers of sandstone and shale, and cooling in a columnar form, gave these cliffs their peculiar

perpendicular formation. They are from 350 to 500 feet in height, broken and fantastic in appearance, and are considered one of the most remarkable and picturesque cliff formations in the world. A considerable amount of rock has been taken from the Palisades for building purposes, and it was feared that they would be badly injured and their beauty destroyed. The two States of New York and New Jersey therefore organized a commission in 1900, known as the Commission of the Palisades Interstate Park, to preserve their natural beauty.

PALISADES INTERSTATE PARK, a great free playground on the west shore of the Hudson River, in the States of New Jersey and New York, extending several miles from Fort Lee northward. In 1900 the two States concerned organized a commission, known as the Commission of the Palisades Interstate Park, the object being "to secure against vandalism and to preserve the natural beauty of the Palisades." As now constituted the park is made up of four distinct sections—the Palisades (q.v.), beginning at Fort Lee and extending 11½ miles northward; Blauvelt, an acreage lying back from the river, west of Nyack; Hook Mountain, a preserve that stretches entirely along the shore front of that rugged mountain promontory commanding the Tappan Zee, and at one point extending back over the summit to Rockland Lake; and Bear Mountain and Harriman Park, a territory that has its shorefront in the heart of the picturesque highlands of the Hudson, and extends thence back, over mountains and valleys, taking in primeval forests, lakes and streams, to the valley of the Ramapo River in the neighborhood of Tuxedo. Roadways have been constructed in recent years, old piles, drifts and rocks along the beaches have been removed, and walls and a shore path constructed, all of which have added much to the accessibility and appearance of the park. Over 15 docks have been constructed for the accommodation of boats and launches. The New Park Drive is the finest automobile road in the eastern part of the country. The Henry Hudson Drive from Englewood Landing is a beautiful pleasure drive. Camping is permitted under certain regulations as to location, payment of fees, etc. In the summer season several steamers stop at the Park landings, especially Bear Mountain. Several ferries also operate from the New York and Yonkers shores. The West Shore Railroad has a station at Bear Mountain. Work on the drives, approaches, spurs, etc., and landscape work are proceeding gradually due to limited appropriations and also to the delays in taking title, under condemnation proceedings, to pieces of land necessary for through routes. Expenditures by Commission, including contributions, appropriations and land donations, total \$13,119,419.

PALISOT DE BEAUVOIS, pǎ'lē'zō də bō'vwā', **Ambroise Marie François Joseph**, **BARON DE**, French naturalist; b. Arras, 1752; d. 1820. He studied law and for some years practised in Paris, after which he became an official in his native province. He soon abandoned official life, however, and began to travel, setting out in 1786 on a trip which took him to West Africa, Santo Domingo and North America. In 1798 he returned to France, was made member of the Institute in 1806, and member of

PALISADES PARK

PALISADES PARK

1 Playgrounds overlooking the Hudson River

2 Boy Scout Camp, combining education and recreation

the Council of the University of Paris in 1815. Palisot was opposed to slavery and during his American tour had altercations with William Wilberforce and Thomas Clarkson on the subject. He published 'Flore d'Oware et de Bénin' (1804-21); 'Insectes recueillis en Afrique et en Amérique' (1806-19); 'Muscologie, ou traité sur les mousses' (1812); 'Essai d'une nouvelle agrostographie' (1813); 'Réfutation d'un écrit anonyme' (1814); and the comedy, 'Railleux.'

PALISSY, pā-lē-sē', **Bernard**, French artist and philosopher: b. La Capella Biron (Lot et Garonne), according to D'Aubigne, 1499, according to other biographers about 1510; d. Paris, 1589. Having been selected in 1543 to draw up the plan of a government survey in his neighborhood the remuneration he received enabled him to carry on experiments in enamels, to which his attention had been accidentally turned, and on which he had for some time been engaged. Being ignorant of the art of the potter he had to grope his way, making experiments with all kinds of materials, which for a long time were unsuccessful. He was compelled at last, by his own account, to burn his furniture in order to keep his oven. The fatigue he endured in conducting himself all the operations necessary to the completion of his discovery was excessive. At length, after 16 years of unremunerated labor (1538-54), he succeeded in producing a pure white enamel, affording a perfect ground for the application of decorative art. He was now able to produce works in which he represented natural objects grouped and portrayed with consummate skill. His reputation rapidly spread, and he acquired a patron in the Duke de Montmorency. His sculptures in clay and his enameled pottery once known became recognized as genuine works of art, and came into demand for the decoration of the houses of the great. Religious persecution, however, which had spared him in obscurity, fastened on him as soon as he had begun to attain to wealth and distinction. He was first imprisoned at Bordeaux on the charge of being a Calvinistic preacher (1562), and was threatened with death, when he was rescued by the Duke de Montmorency, who, to save him from the provincial authorities, procured him the title of *inventeur des rustiques figulines du roi*, with which he went to establish himself at Paris. Here he was patronized by Catherine de Medici, who gave him a site for his furnaces on the present situation of the palace of the Tuileries, where the remains of them were discovered in 1865. Here he continued to work for some years. He also gave for several years in Paris lectures on scientific subjects, the substance of which is probably contained in his 'Discours Admirables' (1580). He was the first in France to substitute facts and demonstrations in the teaching of science for mere hypothesis. He established a rational theory of crystallization, and his classification of salts was nearly perfect. His teaching again excited the jealousy of his theological opponents. He was arrested in 1588 and thrown into the Bastille, where he died at the age of 90, according to D'Aubigne, who knew him personally; or of 80, according to his other biographers. His 'Complete Works' (1880) contain his famous autobiography. A monograph on the artistic

work of Bernard de Palissy by C. De Lange and C. Borneman appeared in 1863-65. A biography of him has been written by Henry Morley (1852).

PALISSY WARE. See **PALISSY, BERNARD**.

PALK (pāk) **STRAIT**, the northern and narrower part of the channel separating Ceylon from the southeastern coast of India, the southern and wider part being the Gulf of Manaar. The strait is 80 miles long, 40 to 85 miles wide, but shallow and scarcely navigable. The Pambam Passage broken with islands connects the two parts of the channel.

PALKI. See **PALANQUIN**.

PALL, pāl (Lat. *palla*), generally, the covering of a bier, but specially applied to the small linen cloth, usually stiffened with cardboard, employed to cover the chalice. The upper part of the pall may be of silk, and colored according to the season. It is often richly embroidered. While part of the corporal is sometimes laid over the chalice as a covering, the pall or palla, according to Pope Innocent III, is not to be considered identical with the corporal. See **COSTUME, ECCLESIASTICAL**.

PALL-MALL (pēl-mēl) **GAME**, an ancient pastime in which a round box-wood ball was struck with a mallet or club and sent through a ring elevated upon a pole, standing at either end of an alley. The game was formerly practised in Saint James' Park, London, and gave its name to the street called Pall Mall.

PALLACEÆ, the stink-horn toadstools. See **FUNGI**.

PALLADIAN ARCHITECTURE, a variety of 16th century Italian architecture so named from Andrea Palladio (q.v.). It was founded upon the Roman antique as interpreted by the writings of Vitruvius, but rather upon the secular buildings of the Romans than upon their temples. It is consequently more applicable to palaces and civic buildings than to churches. A characteristic feature of the style is the use of engaged columns in façades, a single range of these often running through the two principal stories. It was introduced into England by Inigo Jones, a follower of the Venetian school of Palladio.

PALLADINO, pāl'la-dē'nō, **Eusapia**, famous Italian medium: b. 1854; d. May 1918. Her mother died in giving her birth and her father was murdered by brigands a few years later. Of humble origin, she began to work as a kitchen-maid in Naples, and while serving in that capacity she was on one occasion invited by the family to take part in a spiritualistic séance, from which it developed that she possessed remarkable psychic powers. In 1888 she attracted the attention of the scientific world; Professor Lombroso and other scientists went specially to Naples to investigate; committees of investigations were held in Rome, Paris, New York, Cambridge and Warsaw; Sir Oliver Lodge, Professor and Madame Curie, F. W. H. Myers (author of 'Survival After Death'), Richet and Schiaparelli were attracted to and baffled by the mystic phenomena presented by this Italian woman. She converted the scepticism of Lombroso into a faith in spiritualism and led him to write a minute account of her physical peculiarities. A vast literature arose on the subject, and Pal-

ladino became the greatest celebrity in the annals of psychical research in Europe and America. Despite the proven fact that she practised fraud at times, the supernormal character of certain physical phenomena which occurred in her presence has never been explained. For over 20 years she remained an unsolved puzzle and defied solution at the hands of many sceptical investigators. She was able to produce levitations of furniture, graspings by livid hands, the playing of musical boxes and apparitions of the dead. She operated in the light as well as in the dark; a person of very ordinary intelligence, she did not appear to have understood herself the mysteries she provoked.

PALLADIO, pāl-lā'dē'ō, *Andrea*, Italian architect: b. Vicenza, Venetian territory, 30 Nov. 1518; d. Venice, 19 Aug. 1580. He was originally a stone-cutter, and at the suggestion of the poet and savant Trissino (see *TRISSINO*, GIOVANNI GIORGIO), went to Rome for the purpose of studying ancient and modern art. Returning to his native country he designed many palaces and county houses of great beauty and dignity. His designs were also sought in England and other parts of Europe. Palladio belongs to the masters who, in the 16th century, by the study of the works of Roman builders, created a new era in architecture. Among his works the Theatre degli Olimpici, in his native place, is the most important. Venice also owes to him many of her finest buildings. The villa built by Lord Burlington at Chiswick (since enlarged by James Wyatt) was from a design of Palladio, as was also a bridge at Wilton, the seat of the Earl of Pembroke. The majestic simplicity of antiquity was always present to his mind, and Algarotti called him the Raphael of architects. His published works include 'Antichità de Roma' (1554), and 'Quattro libri dell' architettura.' He also provided designs for Barbaro's edition of 'Vitruvius' and illustrated Caesar's 'Commentaries.' His life was written by Temanza (1763). Consult the biography by Fletcher (1902).

PALLADIUM, among the Greeks, a statue or image of Pallas (Minerva), which is said to have fallen from heaven, and to have been found by Ilus, who placed it in a temple in his new city (Ilium). It was believed by the Trojans that their city would be invincible so long as it contained the Palladium. Ulysses and Diomedes, to remove this impediment to the capture of the city, are said to have carried it off. The Romans, however, pretended that it was brought to Italy by Æneas and preserved in the temple of Vesta at Rome. It was considered holy and the protecting divinity of the city. The term palladium has figuratively acquired the sense of bulwark, protection, sanctuary.

PALLADIUM, atomic weight 106.20, a metal resembling platinum, discovered by Wollaston (1803) while purifying a quantity of crude platinum. Occurs native in platinum ores, but principally alloyed with gold and silver in a gold ore from Brazil. Obtained from these ores by complicated processes which ultimately give the palladium as palladium cyanide. This decomposes on ignition, giving pure spongy metallic palladium. A ductile, malleable, white metal, specific gravity 11.50 and having the lowest melting point of all the platinum

metals. It is not acted on by atmospheric oxygen or moisture slowly attacked by strong nitric, hydrochloric, or sulphuric acids, but very easily by aqua regia. In the spongy form it has the power of absorbing gases. Freshly ignited palladium will absorb about 350 times its own volume of hydrogen at room temperature and nearly twice as much when heated to the temperature of boiling water. It forms two compounds with oxygen PdO, palladous oxide, and PdO₂, palladic oxide. Two classes of salts are known related to these two oxides, the palladous salts being the most important. Palladium is used in the manufacture of many fine scientific instruments because of its properties of hardness, color and resistance to the action of the atmosphere, and in jewelry and dentistry is replacing platinum. The nickel ores of Sudbury, Canada, are capable of producing more than the present world's supply of this metal.

PALLADIUS, pa-lā'dī-ūs, Greek patristic writer of the 4th century. His 'Historia Lausiaca' dedicated to Lausus, chamberlain of the Imperial Court, gives us the results of his journeys among the principal districts of the Roman Empire, where monks and hermits had settled. He is indeed the Herodotus of the early Church, whose self-chosen task was to travel from one religious house or colony to another, curiously inquiring about the life of each, and picking up from the gossip of the highway or actual observation a rich fund of information which has enabled him to give a living picture of the ascetic phase of church life in Palestine, Egypt and Syria. His works are published in Migne's 'Patrologia Græca' (Vol. XXXIV). Consult Presschen, 'Palladius and Rufinus' (1897).

PALLADIUS, Peter, Danish leader of the Reformation: b. Ribe, 1503; d. 1560. Palladius was rector of a church at Odense in 1530, when he became a convert to the new doctrines of the Reformers. In 1531 he journeyed to Wittenberg where for six years he studied under Luther and Melancthon, and was made a doctor of theology. Christian III appointed him bishop of Zealand in 1537 and also appointed him to the chair of theology at the university. Palladius worked earnestly and successfully, spreading the Reform doctrines throughout the 390 churches under his jurisdiction. He translated Luther's Little Catechism; compiled a ritual and service book and published a revision of Pedersen's Bible in 1550. In all he prepared over 50 works in Danish and Latin, including the 'Visitatsbog' (1540). Consult the edition of his works by Lis Jacobsen (1911 et seq.).

PALLADIUS, Rutilius Taurus Æmilianus, a Roman writer of the 4th century of our era. He wrote 'De re rustica,' a didactic work in 14 books on agriculture, the topics being arranged according to the seasons, and forming a sort of farmer's calendar. The first book is introductory, and the last, written in elegiac distichs, is a poem on the art of grafting, the other 12 containing accounts of the agricultural and gardening operations for each of the 12 months. Much of the work is simply borrowed from earlier writers. The poem was popular in the Middle Ages and there is an English translation of it belonging to the 15th century.

An English translation by Thomas Owen appeared in 1803, and others have followed.

PALLAH, or IMPALLA, a large reddish, bushranging South African antelope (*Epyceros melampus*), called "roibok" by the Boers. The horns were lyrate, abruptly bent and were possessed by the males alone. These animals were formerly numerous, but were not only especially a prey to the large carnivores, but were shot wrathfully by Boers and sportsmen because they were extraordinarily suspicious and alarmed all the game in the neighborhood by loud whistling cries the moment they discovered a hunter's presence. Now, therefore, they are rare. Consult the works of sportsmen-naturalists in Africa; and Lydekker, 'Book of Antelopes' (1896); Sclater, 'Fauna of South Africa, Mammals' (1900).

PALLAS, pāl'as, freeman and favorite of the Roman emperor Claudius: d. 63 A.D. He was a slave of Antonia, mother of Claudius; was set free by his master when he became emperor; together with Callistus and Narcissus was the real power during Claudius' reign; induced the emperor to marry Agrippina, his own niece, and to adopt Nero; and with the connivance and assistance of Agrippina, now his mistress, poisoned Claudius and brought Nero to the throne. He was subsequently poisoned by Nero's order.

PALLAS, pāl'lās, Peter Simon, German naturalist and traveler: b. Berlin, 22 Sept. 1741; d. there, 8 Sept. 1811. He studied there, in Leyden, and in England, devoting himself especially to the classification of collections of zoological specimens, and in 1768 was invited by Catharine II of Russia to become adjunct of the Saint Petersburg Academy and to lead a scientific expedition through Russia in Asia. This trip of exploration, undertaken with Sokoloff, Suyeff and Rytchkoff, and lasting more than six years, was his greatest work, the specimens collected forming the nucleus of the Academy's museum in Saint Petersburg. In 1777 he became a member of the Imperial Topographical Survey, and in 1787 was appointed historiographer of the College of Admiralty. He retired in 1796 and returned to Berlin not long before his death. His published works include a description of his travels in Asia (1771-76), 'Flora Rossica' (1784-1815); 'Icones Insectorum' (1781-98); a study of the Mongolian races (1776-1802); and a great and incomplete 'Vocabularium Linguarum totius Orbis' (1787-89).

PALLAS, pāl'as, in astronomy, one of the minor planets revolving round the sun between Mars and Jupiter. It was discovered in 1802 by Olbers at Bremen. It revolves round the sun in 4.61 years. The eccentricity of its orbit is 0.23969, and its semi-axis major is 2.77 times that of the earth's orbit. Its diameter is 172 miles. When nearest the earth in opposition, Pallas shines as a full seventh-magnitude star, with a decided yellowish light.

In Greek mythology, the goddess of wisdom. See MINERVA.

PALLAVICINO, pāl-lā-vē-chē'nō, Ferrante, Italian satirist: b. Piacenza, 1618; d. Avignon, 6 March 1644. He took orders; became a canon of Augustine; had to escape to Venice because of his broken vows; wrote there against Odoardo, Duke of Plaisance, but

had to leave Venice in turn because of his immoral life and writings; spent some time in Germany; again went to Venice, where he was imprisoned, but soon set free; then broke entirely with the Church and bitterly and foully attacked the Pope in 'Il divorzio Celeste.' Venturing into France he was arrested by the papal officers, found guilty of heresy and beheaded.

PALLAVICINO, pāl'la-vē-chē'nō, Sforza, Italian cardinal and ecclesiastical historian: b. Rome, 1607; d. there, 1667. He was educated in the Collegio Romano; was made governor successively of Iesi, Orvieto and Camerino by Urban VIII; at 30 entered the Jesuit Order; soon afterward became professor of philosophy and theology in the Roman College; and made such a name by his philosophical treatises that he was chosen by the Catholics to write a party history of the Council of Trent which refuted the work of Paolo Sarpi.

PALLEN, Condé Benoist, editor, poet and essayist: b. Saint Louis, Mo., 5 Dec. 1858; descended from two of the oldest French families among the pioneers of the Louisiana Purchase. Dr. Pallen made his college course at Georgetown University, District of Columbia (A.B. 1880; A.M. 1883; LL.D. 1896); took a special course of study at Saint Louis University; received the degree of Ph.D. in 1885. For 10 years (1887-97) he edited the *Church Progress* of Saint Louis; since 1885 has been a well-known figure in the lecture field on literary, philosophical and economic subjects. He is author of 'The Philosophy of Literature'; 'Epochs of Literature'; 'What is Liberalism'; 'New Rubaiyat'; 'The Feast of Talarchus' (dramatic poem); 'The Death of Sir Launcelot, and Other Poems'; 'The Meaning of the Idylls of the King'; and 'Collected Poems.' His interpretation and comments on the 'Idylls' drew from Tennyson himself a personal letter of congratulation and appreciation. He has been a contributor to magazines for the past 30 years; Catholic revisory editor of 'The New International Encyclopedia,' and the 'Encyclopedia Americana' (1st edition), and managing editor of the 'Catholic Encyclopedia'; president of The Encyclopedia Press, Inc., since 1912.

PALLIS, pāl'lēs, Alexander, Greek litterateur: b. Pieræus, Greece, 1851. Pallis became a firm advocate of the popular Greek speech as opposed to the literary language affected by the Church and press and gained notoriety by a popular version of the Gospel of Matthew, which appeared in the journal *Akropolis*. Riots ensued and the Synod prohibited all modern Greek versions of the Scriptures in Greece. In 1902 in Liverpool, England, he published his translation of the four Gospels and the following year witnessed the publication of 'A Few Notes on the Gospels according to Saint Mark and Saint Matthew.' In 1904 he was joint translator of Kant's 'Kritik' and in the same year published a version of the 'Iliad.' In 1906 appeared a version of Euripides' 'Cyclops' and in 1907 an original volume of 'Poems.' Pallis has for several years been engaged in mercantile pursuits in Liverpool. Consult Krumbacher, K., 'Das Problem der neugriechischen Schriftsprache' (Munich 1902).

PALLISER, pāl'i-sér, SIR William, British inventor and engineer: b. Dublin, 18 June 1830; d. 4 Feb. 1882. He passed through the Staff College at Sandhurst, and in 1855 obtained a commission in the Rifle Brigade, was subsequently transferred to the Hussars and retired from the army in 1871. Besides inventing the projectiles and guns which bear his name he devised many improvements in fortifications, etc. He was knighted in 1873, and for a few years sat in the House of Commons as Conservative member for Taunton. See **PROJECTILES**.

PALLIUM, an article of ecclesiastical dress consisting of a band of white wool, some three inches wide, with two narrower bands of the same material, one of which hangs down the back and the other over the breast. It is embroidered with four purple crosses. It is a part of the vestments of the pope, patriarchs and archbishops; and is sent by the pope to the patriarchs and archbishops as a token that they are invested with the fullness of the episcopal office. It is sometimes, though rarely, also sent to bishops. When a bishop is elected or appointed to a metropolitan see, he at once solicits the pallium from the pope within three months after his consecration or confirmation. The pallium is made from the wool of two lambs annually presented in the church of Saint Agnes, Rome, by the apostolic sub-deacons, and woven by the nuns of Torre de' Specchi, to whom alone belongs the privilege. The historical origin of the pallium is not known or at least wrapt in such obscurity that no definite conclusion has ever been arrived at. Some writers believe that it was first conferred upon bishops by the emperors as a mark of dignity, and then passed over to a purely ecclesiastical usage. It is only worn on occasions of great solemnity. Consult Thurston, 'The Pallium' (London 1802); Vespasiani, 'De Sacri Palli Origine' (Rome 1856).

PALM, pām, Johann Philipp, Bavarian bookseller and publisher: b. Schorndorf, Bavaria, 1768; d. Braunau, Bohemia, 26 Aug. 1806. The firm of which he was a member published a pamphlet, 'Germany in Her Deepest Humiliation' (1806), which was hostile to Napoleon and his measures. It was brought to the attention of Napoleon, who ordered the arrest of Palm, had him tried by court-martial, and though the pamphlet was to the publisher merely trade matter, he was sentenced to death and executed at Braunau on the following day. This act aroused the deepest indignation in Europe as well as in Germany, where the hatred of the Germans for Napoleon was already intense. Consult Schultheiss, 'Johann Philipp Palm' (1860).

PALM BEACH, Fla., winter resort in Palm Beach County, on the Florida East Coast Railroad, the East Coast Canal and Lake Worth, 300 miles southeast of Jacksonville. Its climate, location and ample facilities for boating, bathing and fishing combine to make Palm Beach the most popular of winter resorts. There are a number of palatial hotels and beautiful parks. Farming and fishing interests are considerable and the reclamation of the Everglades is making a large acreage available for tillage. Pop. (permanent) 1,200; (winter) 6,000-7,000.

PALM BUTTER, OIL, SUGAR, WAX. See **PALMS**.

PALM-CAT, or **PALM-CIVET**, any of several animals of the civet family (*Viverridæ*), and of the genus *Paradoxurus*, known also as tree-cats, toddy-cats, from their habit of climbing palm-trees to eat their fruit. They inhabit India and southeastern Asia, the Malay Archipelago, etc., and somewhat resemble large cats with comparatively short legs. The best known is the Indian species (*P. niger*), which is often kept about houses and subsists mainly on animal food, such as rats, small birds, lizards, etc. Consult Blanford, Jerdon, Blyth, Wallace and other authorities on East Indian zoology; and Allen's Natural History, article 'Cats, Civets and Mongoose' (1894).

PALM-CRAB, a large burrowing land-crab which feeds upon coconuts. See **ROBBER-PALM**.

PALM-KALE, a variety of cabbage extensively cultivated in the Channel Islands and also in Italy. It grows to the height of 10 or 12 feet, and with a crown of leaves at top it has much the aspect of a palm.

PALM OIL. See **PALMS**.

PALM SUNDAY, the Sunday next before Easter Day, so called because on that day is celebrated Christ's last entry into Jerusalem before his Passion, where palm branches were strewn in his way by the multitude. In some churches palms are employed as decorations at the services on this Sunday, and fragments of them distributed to the people.

PALM-SWIFT. See **SWIFT**.

PALM-WEEVIL, or **GRUGRU**, a large curculionid beetle (*Rhyncophorus palmarum*). See **GRUGRU**.

PALMA, Giacomo, jā-kō'mō pāl'mā, called IL VECCHIO, Italian painter: b. probably Serintola, near Bergamo, about 1480; d. Venice, 1528. He is supposed to have been a pupil of Giovanni Bellini, but little is known regarding his life. It may be divined from the pictures that go by his name that he imitated one after another several great artists of the Venetian school and many of his works have been attributed to Giorgione, whose coloring he took for his standard of excellence. The Italian churches have multitudinous examples of paintings called "Santa Conversazione" representing the Virgin and the Child, and the donor of the picture presented to them by his patron saint. Of these large compositions Palma Il Vecchio painted very many. He was also successful in mythological subjects, and his landscape backgrounds are exquisite. His works place him among the foremost painters of his time. Some of his best-known paintings are 'Adoration of the Shepherds'; 'The Holy Family'; 'Mars and Venus'; 'The Mystical Marriage of Saint Catherine'; 'Divine and Heathen Love'; 'Portrait of Andrea Palladio in his Youth.'

PALMA, Giacomo, called IL GIOVANE, Italian painter, grand-nephew of the Elder Palma: b. Venice, about 1544; d. there, 1628. His early work was excellent, comparing in fresh coloring with Titian, who greatly influenced him. Later his vicious mannerism grew so as to be a predominating feature of his work.

Hence Lanzi called him the last good and first bad painter of Venice.

PALMA, Ricardo, Peruvian author: b. Lima, Peru, 7 Feb. 1833. He was exiled to Chile in 1860 as a result of implication in a political revolt, but upon his return became secretary to President Balta. Later he served as senator and then was assistant in the National Library. After the sack of the library by the Chileans in 1881 he reorganized it, gathered remaining fragments and assisted by gifts from foreign governments succeeded in reopening the library in 1884. In 1886 he promoted the agitation which resulted in the expulsion of the Jesuits from Peru. He is the author of several works of fiction, some poetry, the historical work 'Anales de la Inquisición de Lima' (1863), 'Poésias' (1887) and 'Tradiciones y artículos históricos' (1899), recording the traditions and legends of Peru.

PALMA, Thomas Estrada, Cuban patriot: b. Bayamo, Santiago province, Cuba, 15 July 1835; d. Santiago province, Cuba, 4 Nov. 1908. He studied law, but did not practise; during the revolution of 1868-78 rose to be a general in the Cuban forces; after nearly nine years of service was captured and imprisoned in Spain until the close of the insurrection. At the time of his imprisonment he had succeeded Cespedes in the rather empty honor of President of the Cuban provisional government. After his release he went to Honduras, where he became Postmaster-General of the republic. Later he removed to the United States, where he opened a school for Latin-Americans at Central Valley, N. Y. This institution he successfully conducted until the beginning of a fresh revolt in Cuba in 1895, when he was elected delegate-at-large and Minister Plenipotentiary of the Cuban republic and took charge of the well-known Junta in the United States, which purchased arms, organized filibustering expeditions and otherwise aided the army in the field. In 1901 Palma was almost unanimously elected President of the republic and on 20 May 1902 was inaugurated, the United States on that day turning over to the new government the administration of the internal affairs of the nation. On 23 Sept. 1905 he was again elected to the office of President but resigned 28 Sept. 1906.

PALMA, (1) the capital of Majorca (q.v.), the largest of the Balearic Isles and of the Spanish province of Baleares, on the Bay of Palma indenting the south coast. The city, encircled by a fortified wall, stands in the midst of orange plantations and with its Moorish architecture has a very picturesque effect. It is one of the most aristocratic of European cities. A railway connects it with Manacoor on the east coast. Its chief edifice is the Gothic cathedral (1322-1601); it contains the tomb of King Jayme II of Aragon and a valuable collection of church ornaments. In the church of Saint Francis is the tomb of Raimon Lully (q.v.). Other notable structures are a fine exchange (1426-46), an old Moorish palace, a 16th-century town-hall and several fine modern buildings and institutions. Its numerous manufactures include woven silks and woollens, jewelry, etc., and it has considerable trade in wine, oil, cattle and agricultural produce. Its fine harbor is protected by a mole. Pop. about 68,000.

(2) A town of Sicily, 14 miles southeast of Girgenti. Pop. 11,702. (3) The name of one of the larger of the Canary Islands (q.v.).

PALMA CHRISTI. See CASTOR-OIL PLANT.

PALMÆR, pal-mär', Vilhelm, Swedish chemist: b. Forsvik, Skaraborg, 1868. He received his education at the universities of Upsala and Göttingen, held several teaching positions and in 1907 was appointed to a chair in the Stockholm Technical College. He traveled in Germany, France, America, Switzerland and England. Dr. Palmær has been secretary to the Nobel committee of the Academy of Sciences since 1900. His published works include 'Ueber der Mirkungsart der Tropfelektroden' (1898); 'Chemische Nachweisung der Konzentrationsänderungen bei Tropfelektroden' (1899); 'A Brief Account of Dr. V. Palmær's Electrolytic Process for Producing Bicalcic Phosphate' (1904) and contributions in scientific journals and periodicals.

PALMAS, päl-mäs, Cape. See CAPE PALMAS.

PALMER, pä'm'ër, Alice Freeman, American educator: b. Colesville, N. Y., 21 Feb. 1855; d. Paris, France, 6 Dec. 1902. She was graduated from the University of Michigan in 1876. From 1877 to 1879 she was principal of the high school at East Saginaw, Mich., becoming in the last-named year professor of history in Wellesley College. In 1882 she became acting president and later president of that institution, which position she retained till her marriage in 1887 to Prof. G. H. Palmer (q.v.) of Harvard University. During her administration the standard of scholarship was raised, the number of students very greatly increased and several important buildings added. In 1892-95 she served as non-resident dean of the woman's department of the University of Chicago. She took an active interest in educational and reform associations, was a member of the Massachusetts State board of education from 1889.

PALMER, Anthony, American colonial governor: b. England, about 1675; d. Philadelphia, Pa., May 1749. He was a merchant in Barbados for some time, but in 1707 purchased a large tract of land in Philadelphia where he then settled. In 1708 he was a member of the provincial council and served until his death. When Lieut.-Gov. George Thomas resigned in 1747 the government devolved upon Palmer, who was president of the executive council, and during the succeeding 18 months he administered the affairs of the colony with much ability. He conciliated the Indians and took precautions for the military defense of the colony against Spain and France, though opposed by the Quaker members of the council. The "Kensington District" of Philadelphia was originally a portion of his farm.

PALMER, Arthur Hubbell, American Germanic scholar: b. Cleveland, Ohio, 30 June 1859; d. 6 Nov. 1918; graduated at Western Reserve University, 1879, and subsequently studied for two years in Europe. From 1883 to 1891 he was professor of the German language and literature and from 1886 to 1891 also served as librarian at Adelbert College. After 1891 he held the chair of German language and literature at Yale University. Professor Palmer was a trustee of the American Scandinavian Founda-

tion of New York. He edited Richl's 'Burg Neideck' (1893); Schiller's 'William Tell, with Introduction, Notes and Vocabulary' (1898; 1915); Schiller's 'Thirty Years' War' (1899); Goethe's 'Hermann und Dorothea' (1903); translations of Björnson's 'Poems and Songs' (1915).

PALMER, Sir Charles Mark, English iron-master and shipbuilder: b. South Shields, 3 Nov. 1822; d. London, 4 June 1907. He was educated for a commercial career in France; was partner in several coal companies; reformed the coal-carrying trade from the north of England by building screw colliers (1852), which drove the sailing brigs out of business; and at Jarrow established a great shipyard. Both iron and coal for this yard are supplied by Palmer's own mines. He introduced the use of rolled plates for men-of-war; held several important government contracts; and was a member of the House of Commons, 1874-1907. He was created a baronet in 1886.

PALMER, Edward Henry, English Oriental scholar: b. Cambridge, 7 Aug. 1840; d. Arabia, 1 Aug. 1882. He was educated at Saint John's College, Cambridge, and later made extensive journeys of exploration in the East. In 1871 he was appointed professor of Arabic at Cambridge and from that time onward accomplished a vast amount of literary work. In 1874 he was called to the bar. In 1882 he was engaged by the British government to assist in keeping the Arabs of the Sinai region quiet and preventing them from interfering with the Suez Canal, when he was captured and murdered with two other Englishmen. He had a remarkable knowledge of Oriental life and language and was a man of very varied gifts. His works include 'Oriental Mysticism' (1867); a 'Grammar of the Arabic Language' (1874); 'A Concise Dictionary of the Persian Language' (1876); 'The Song of the Reed' (1877), comprising Persian verse translations and original poems; 'The Poetical Works of Behâ-ed-Din Zoheir of Egypt, with a Metrical English Translation, Notes and Introduction' (1876-77); a translation of the Koran ('Sacred Books of the East,' 1880); a 'Life of Haroun Alraschid' (1881); an Arabic manual (1881); and a 'Simplified Grammar of Hindustani, Persian and Arabic' (1882). Consult 'Life' by Besant (1883).

PALMER, Erastus Dow, American sculptor: b. Pompey, N. Y., 3 April 1817; d. Albany, N. Y., 9 March 1904. His best-known works were 'Morning and Evening'; 'The Angel of the Sepulchre'; 'The White Captive'; 'Landing of the Pilgrims' (a group of 15 life-size figures intended for the Capitol at Washington). He also executed many portrait busts and statues, including the statues of Washington Irving, Alexander Hamilton and Robert R. Livingston, the latter in the national Capitol. The Livingston statue brought him a gold medal at the Centennial Exposition in Philadelphia in 1876. The 'Indian Girl' at the Metropolitan Museum in New York was the first full length figure he attempted.

PALMER, Frederick, author and war correspondent: b. Pleasantville, Pa., 29 Jan. 1873. He was graduated at Allegheny College 1893; acted as correspondent during the Greco-

Turkish War '97; Alaskan sledge journey, Philippine '98; March to Peking, 1900; Siberian travel, 1902; with Kuroki's army for *Colliers and London Times*, 1904-05; cruise American battleship fleet, 1908-09; Mexico and Central American travels, 1909; Balkan War, 1912; Mexico, 1914. Chosen as the one accredited correspondent to represent the American press with the British army, 1914-16, and various smaller campaigns. Author of 'Going to War in Greece'; 'The Ways of the Service'; 'The Vagabond' (novel); 'With Kuroki in Manchuria'; 'Central America and Its Problems'; 'The Last Shot' (novel) and 'My Year of the Great War.'

PALMER, George Herbert, American educator and classical scholar: b. Boston, 19 March 1842. He was graduated from Harvard in 1864, studied at the University of Tübingen, 1867-69 and at Andover Theological Seminary in 1870; and after serving as tutor in Greek at Harvard, 1870-73; assistant professor, 1873-83, and professor of philosophy, 1883-89, became Alford professor of natural religion there in 1889, and professor emeritus 1913. He published a rhythmic prose translation of the 'Odyssey' (1884); 'The New Education' (1887); 'The Glory of the Imperfect' (1898); 'Self Cultivation in English' (1897); 'The Antigone of Sophocles,' a translation (1899); 'The Field of Ethics' (1901); 'The Nature of Goodness' (1904); 'The English Works of George Herbert' (3 vols., 1905); 'The Life of Alice Freeman Palmer' (1908); 'The Teacher' (1909); 'The Problem of Freedom' (1912); 'Intimations of Immortality, in the Sonnets of Shakespeare' (1912); and also edited the 'Poems of Alice Freeman Palmer' (1915). He received the honorary degrees of Litt.D. Western Reserve, 1897; Princeton, 1912; LL.D. Michigan, 1894; Union, 1896; Harvard, 1906; Dartmouth, 1909.

PALMER, Herbert James, Canadian statesman: b. Charlottetown, Prince Edward Island, 1851. He received his education at Prince of Wales College, Charlottetown, and at King's College, Windsor, Nova Scotia, and in 1877 was called to the bar. He became a member of the Provincial Parliament in 1900 as a Liberal; was attorney-general in 1908; and for a few months in 1911 was Premier. In 1910 he was a delegate to the Conference on Representation of the Maritime Provinces in the Dominion Parliament, held at Saint John, New Brunswick.

PALMER, James Shedden, American naval officer: b. New Jersey, 1810; d. Saint Thomas, West Indies, 7 Dec. 1867. Entering the navy in 1825 as midshipman, he was made lieutenant in 1836. In the war with Mexico he commanded the *Flirt*, a blockade-schooner, in 1855 became commander, and when the Civil War broke out was with the Mediterranean squadron and in command of the *Iroquois*. Recalled from that station, he joined the blockading fleet under Admiral Dupont. In 1862 he was promoted to a captaincy, and in the passage of the batteries at Vicksburg held the advance of the Union vessels. At New Orleans and Mobile Bay he performed important services as flag-captain to Farragut, with whom his relations were most intimate. Made commander in 1863, he rose to the rank of rear-admiral in 1866, and until his

death was in command of the North Atlantic squadron.

PALMER, John McAuley, American soldier and politician: b. Eagle Creek, Scott County, Ky., 13 Sept. 1817; d. Springfield, Ill., 25 Sept. 1900. He attended Shurtleff College, Upper Alton, Ill., for a year, and later studied law and was admitted to the Illinois bar in 1839. He first entered politics in the campaign of 1840, when he actively supported Van Buren; in 1843 he was elected probate judge of Macoupin County; in 1847 was a delegate to the State Constitutional Convention; and in 1849 was elected county judge. In 1852 he was elected to the State senate and re-elected in 1854. His opposition to the Kansas-Nebraska bill, however, led him to sever his connection with the Democrats, and ally himself with the Republican party. He was active in the organization of this party, was president of the Republican State Convention in 1856, and delegate to the National Convention of the same year and that of 1860. He was one of the representatives of his State at the Peace Conference in Washington 1861. At the outbreak of the Civil War he joined the army as colonel of an Illinois regiment, took part in the Springfield campaign, and in December 1861 was promoted brigadier-general; in 1862 he was made major-general, in 1863 given command of the 14th corps and later of the Department of Kentucky. He took part in the operations against Island No. 10 (1862), led a division at Murfreesboro (1862) and at Chickamauga (1863); as commander of the 14th corps he was engaged in the battles of Chattanooga (1863), Kenesaw Mountain and Peach Tree Creek (1864), and in the Atlanta campaign. After the war he continued his law practice in Illinois, and in 1868 was elected governor of the State; during his administration he steadily resisted special legislation and the granting of special privileges. In 1872 he left the Republican party and supported Greeley for the Presidency, and in 1876 was one of the most active supporters of Tilden. In 1890 he was nominated for United States senator by the Democrats, and elected, serving for six years. In 1896 he was nominated for the Presidency by the Gold Democrats, who refused to accept the regular nominations on account of the free silver plank of the platform. He wrote his autobiography, published under the title 'Personal Recollections of John M. Palmer.'

PALMER, John Williamson, American author: b. Baltimore, Md., 4 April 1825; d. there, 26 Feb. 1906. He was graduated from the University of Maryland as a physician in 1847; was city physician in Baltimore, 1849-50, and subsequently went to China and India as a surgeon in the service of the East India Company. He was connected with the staff of the Century and Standard dictionaries, and his care and accurate rendering of Hindu terms in those works has added much to the Western knowledge of Anglo-Indian terms. Among his publications are 'The Golden Dragon; or, Up and Down the Irrawaddy' (1853); 'The New and the Old; or, California and India in Romantic Aspects' (1859); 'After His Kind,' a novel (1886); 'The Poetry of Compliment and Courtship' (1867); 'For Charlie's Sake and Other Lyrics and Ballads' (1901); and 'Stonewall

Jackson's Way,' one of the most popular ballads of the Civil War.

PALMER, Nathaniel Brown, American sea-captain: b. Stonington, Conn., 1799; d. 1877. He went to sea at 14 and in 1821 he commanded the sloop *Hero* which set sail from Yankee Harbor in South Shetlands on an exploring expedition. He discovered the land known as the Palmer Archipelago, which at the time was supposed to be a portion of the Antarctic continent. It is now called Palmer's Land, being located in lat. 63° S., near Tierra del Fuego. He followed a seafaring life until 1849 and was afterward a director of the Fall River line of steamships. Consult Greeley, 'American Discoverers of the Antarctic Continent' (1912).

PALMER, Ray, American Congregational clergyman and hymnologist: b. Little Compton, R. I., 12 Nov. 1808; d. Newark, N. J., 29 March 1887. He was graduated at Yale in 1830; studied theology and entered the Congregational ministry. He was pastor of churches at Bath, Me., 1835-50, and Albany, N. Y., 1850-66; and secretary of the Congregational Union in New York City, 1866-78. He was the author of many sacred hymns, of which the best known is 'My Faith Looks Up to Thee,' included in very many collections of church hymns and translated into more than 20 languages. His published volumes are 'Hymns and Sacred Pieces' (1865); 'Hymns of My Holy Hours' (1868); 'Voices of Hope and Gladness' (1880).

PALMER, Samuel, English painter: b. Newington, Lancashire, 27 Jan. 1805; d. Reigate, Kent, 24 May 1881. He was a pupil in the antique school of the British Museum, and received some inspiration from his acquaintance with William Blake. His studies were for two years continued at Rome (1837-39) after which he devoted himself to water colors and became a member of the Water Color Society in 1854. While belonging to the ideal school of Turner and Wilson he confined himself entirely to water color and etching, in both of which departments he reached the highest excellence. Among his best-known pictures which are suffused with profound poetic feeling are 'Dream on the Apennines' (1864); 'Curfew' (1870); and 'The Waters Murmuring' (1877). His finest etchings include 'The Sleeping Shepherd'; 'The Skylark'; 'The Lonely Tower.' He translated the Eclogues of Virgil and intended to illustrate them, but only lived long enough to complete one plate, 'The Opening of the Fold.'

PALMER, Thomas Witherell, American legislator: b. Detroit, Mich., 1830; d. 1913. He was educated at the University of Michigan and traveled extensively in Spain and in South America. He was engaged in real estate operations from 1853 to 1872. In 1873 he was elected to the Detroit board of estimate and five years later became a member of the State senate. He was unsuccessful Republican nominee for governor in 1880, but became United States senator in 1883. President Harrison sent Palmer as Minister to Spain in 1889 where he remained two years. Soon after his return he was elected president of the World's Columbian Commission.

PALMER, Walter Launt, landscape artist: b. Albany, N. Y., 1 Aug. 1854. After studying

under F. S. Church at Hudson, N. Y., he became the pupil of Carolus Duran at Paris and developed great skill in landscape painting, specializing in winter landscapes. He was awarded a gold medal at the World's Columbian Exposition in 1893, honorable mention at the Paris Exposition of 1900 and subsequently received numerous other awards and honors. His Venetian scenes and snowy landscapes are remarkably effective and among his best productions are 'Venice' (1882); 'January' (1887); 'Domes of La Salute'; 'End of a Winter Day'; 'Under the Pines' (1896); 'Sundown at Walpole, N. H.' (Buffalo Academy 1901); 'Oaks in Winter' (1906); 'The Glade' (1913); 'The Sleeping Brook' (1914); 'The Frozen Lake' (1915). He is a member of the National Academy; of the Society of American Artists and the American Water-Color Society.

PALMER, in mediæval times a term applied to a pilgrim who had visited the Holy Land and carried on his return a branch of the palm for a staff as a memorial of his journey. The name was also given to itinerant monks or religious men who wandered from shrine to shrine without a fixed home.

PALMER, Mass., town, Hampden County, on the Chicopee, Swift and Ware rivers, and on the Boston and Albany and Central Vermont railroads, 14 miles east of Springfield. It includes the villages of Palmer, Three Rivers, Bondsville, Thorndike and Duckville, of which the first two are the most important. It was first settled in 1716 by John Kingston, and was incorporated as a town in 1775; for several years previous to its incorporation (1741-52) it was called Kingston. It is an enterprising industrial town and manufactures cotton and woolen goods, carpets, foundry and machine-shop products, wire, wire nails, hats, etc. It has a public and an association library and the Massachusetts Hospital for Epileptics. Pop. 9,896. Consult Temple, 'History of the Town of Palmer, Mass.' (Palmer 1889).

PALMERIN (pāl'mēr-in) **OF ENGLAND** (**PALMERIN DE INGLATERRA**), a romance of chivalry in the style of 'Amadis of Gaul,' and in this class of literature regarded as second only to it in point of merit. It is this book, which with 'Amadis,' Cervantes saves from the holocaust in 'Don Quixote.' It was long supposed to be the work of Francisco Moraes, a Portuguese, who published it in 1567 as a translation from the French, and in 1807 Southey published an English translation, attributing the original to Moraes, and credited him with modesty in not claiming the authorship. It has since been found to have been the work of Leon Hurtado, and to have been published originally in Spanish, in Toledo, in 1547. This story is in some respects a continuation of 'Palmerin de Oliva.'

PALMERIN DE OLIVA, pāl-mā-rēn' dā ō-lē-vā, a romance of chivalry, a feeble imitation of 'Amadis of Gaul,' first published in Salamanca in 1511. It has generally been considered to be of Portuguese origin; but Ticknor, in his 'History of Spanish Literature,' asserts that the author of it was a carpenter's daughter in Burgos. This is one of the books against which Cervantes inveighs as re-

sponsible for the mental condition of Don Quixote; and in the famous scene of the burning of the books of chivalry, he says: "This Oliva, let it be hewn in pieces and burnt, and let not the very ashes be left." A continuation by the same author, 'The Second Book of Palmerin,' which treats of the adventures of his sons, Primaleon and Polendos, appeared later.

PALMERSTON, pām'ēr-stōn, **Henry John Temple**, **VISCOUNT**, English statesman: b. Romsey, Hampshire, 20 Oct. 1784; d. Brockett Hall, Hatfield, Hertfordshire, 18 Oct. 1865. He was educated at Edinburgh University and at Saint John's College, Cambridge, being graduated from the latter in 1806. He had succeeded in 1802 as 3d Viscount Palmerston in the Irish peerage, a title which did not disqualify him from sitting in the House of Commons. In 1806 and 1807 he was the Tory candidate for Parliament from Cambridge University, and was both times defeated, but in 1807 was elected to Parliament from Newton, Isle of Wight. In 1809 he succeeded Lord Castlereagh as Secretary at War, and in 1811 was elected member of Parliament for Cambridge University. As Secretary of War he carried out a vigorous reform of the details of administration; regulated the finances, paid off arrears and reduced the previous confusion of the War Office to order. He mainly confined himself in his Parliamentary speeches to the business of his department, but also spoke on Catholic Emancipation, of which he was always a supporter. He retired from office in the Wellington ministry in 1828 with others of the Canning party. In 1830 he became Foreign Secretary in the Whig ministry of Earl Grey, and from this time continued a member and leader of the Whig party. In 1831 he lost his seat for Cambridge, but was elected from Blethingley, then from South Hants, and in 1835 from Tiverton, which borough he continued to represent till his death. It was during his service as Foreign Secretary that he earned a reputation for vigilance and energy in the conduct of foreign affairs, and especially for guarding the interests of individual Britons abroad, which, while it increased his popularity at home, gained him enemies abroad. He succeeded in establishing and maintaining friendly relations with France so that the two nations acted in concert; took a leading part in gaining the independence of Belgium, and in establishing constitutional government in Spain and Portugal. He supported Austria and Turkey against Russia, in the East, and took part in the war against Mehemet Ali. In Parliament he supported the liberal policy of free trade and labor laws regulating hours, factory conditions, etc. He was Foreign Secretary till 1841, when the Whig ministry went out of office on the question of free trade in corn, but on the Whigs' return to power in 1846 he again took that office, under Lord Russell. During the period of 1848-49 he manifested his liberal tendencies and sympathy with the revolutionary party without actively interfering with the affairs of foreign states. Several of his acts in this administration aroused party criticism, especially his favoring the cause of a Portuguese Jew at Athens, Don Pacifico, a naturalized British subject, which caused a quarrel with Greece and nearly produced a war with France. This

was the occasion of a keen discussion of his policy in Parliament, which resulted in a formal vote in the House of Commons approving the foreign policy of the government. In 1851 he unofficially expressed to the French Ambassador in London his approbation of the *coup d'état* of Louis Napoleon, without consulting either his colleagues or the queen, and he was forced to resign. In the next year he defeated the Russell ministry on the question of the Militia bill, but refused to accept a position in the cabinet under Lord Derby. In December 1852 he took office as Home Secretary in the coalition ministry of the Earl of Aberdeen, and on the resignation of this ministry, in consequence of alleged mismanagement of the Crimean War, he was, on the almost universal demand of the country, called to the premiership, and vigorously carried on the war with Russia. In 1857 Parliament, on the motion of Richard Cobden, passed a vote of censure on the conduct of the Chinese War; dissolution of the House gave Palmerston a majority, but in February 1858, he resigned, after being defeated on the Conspiracy bill; he returned to power in June 1859, and continued to hold the premiership during the remainder of his life and at the time of his death had held office for nearly 50 years.

Among the important events of his last administration were the American Civil War (with the recognition of the Confederate States as belligerents and the *Alabama* incident), the Prussian War against Denmark, which he opposed, and the union of Italy, which he strongly favored. Consult the official 'Life' by Dalling, continued by Ashley (1870-76); 'Lives' by the Marquis Lorne (1891); Sanders (1888) and Trollope (1882) and Francis. 'Opinions and Policy of Viscount Palmerston' (1852).

PALMETTO. See PALMS.

PALMETTO STATE, a name applied to South Carolina. The palmetto tree appears on the coat of arms of the State. See SOUTH CAROLINA.

PALMIERI, pāl-myā'rē', **Aurelio**, Italian missionary and author: b. Savona, Italy, 4 May 1870. He was educated at the Seminary of Maria and the Augustinian Convent, Naples. In 1885 he entered the Augustinian Order, was sent to Constantinople in 1894 and was ordained in 1895. He was successively professor of theology and canon law and assistant pastor and missionary, Kadi-Keui, Constantinople. In 1905-07 he prosecuted Oriental studies in Rome and from 1907-10 was stationed at Cracow, Poland. He takes an active part in the biennial congress at Velehrad, Moravia, for the union of Christendom, and has traveled in Russia making a collection of Russian publications for the Vatican Library. His publications include 'Die Polenik des Islam' (1902); 'La chiesa russa' (1908); 'Vita di Dositeo, Patriarca di Gerusalemme' (1909); 'Il Progresso Dommatico' (1910); 'Nomenclator theologiæ græco-russicæ' (2 vols., 1910-11); 'Theologia dogmatica orthodoxa' (1911). Dr. Palmieri collaborated in 'Dictionnaire de théologie catholique,' 'Dictionnaire de biographie et d'histoire ecclésiastique,' and contributed to 'Oriens Christianus,' 'Civiltà Cattolica,' 'Studi religiosi,' *Rivista di apologia cristiana*, etc.

PALMIRA, pāl-mē'ra, Colombia, town and capital of Palmira province, department of

Valle del Cauca, 160 miles southwest of Bogotá, situated in the Llanos de Malagana, a plain famous as a thriving agricultural region. Tobacco is grown extensively. The town dates from 1794. Pop. 24,312.

PALMISTRY, the art by which one professes to discover the temperament and character of any one, as well as the past and future events of his life, from an examination of the palm of his hand and of the lines traced upon it. As a considerable body of very complicated rules and directions have been laid down by authorities, ancient and modern, to enable the student to read the palm, palmistry claims to be regarded as a "science," or at least as a branch of an interpretative science of the hand in general, to which the name *Chirosophy* has been given. The other branch of this general science has been called *Chirognomy*, and is concerned with the interpretation of the form and character of the hand and fingers, while palmistry treats of the palm only. The science was known to the early Chinese, to the ancient Greeks and was somewhat popular on the Continent during the Middle Ages. The chief authorities on palmistry in recent times are two Frenchmen, M. le Capitain D'Arpentigny and M. Adrien Desbarrolles; and it is on their works that modern English books on the subject are chiefly founded. The observation of the fingers and joints on the hand is quite as important to the palmist as that of the palm itself. The thumb is generally regarded as chirognomically the most important part of the hand. The first, or upper phalange of the thumb, when well developed, shows the presence of will and decision of character; the second, according to its development, indicates more or less logical power. What has to be considered by the chiromant proper is the "mounts" of the hand, with the marks on them, and the lines in the palm. The "mounts" are the elevations at the base of the fingers and thumb and in the "percussion" of the hand—that is, the side of the palm which extends from the root of the little finger to the wrist; it is so called because it is used in striking. They are seven in number and are named from the planets. See CHIROMANCY.

PALMITIN, PALMINE, or TRI-PALMITIN, a fatty substance occurring quite commonly in the natural fats and organic oils, and closely analogous to stearin in its chemical structure and deportment. It is especially abundant in palm oil, from which circumstance it derives its name. Tri-palmitin may be conveniently prepared from palm oil by expelling the liquid portion by pressure, washing the solid residue with boiling alcohol to remove such other fats as it may still retain, and finally crystallizing from a solution in ether. By this process it is obtained in the form of white crystals which are scarcely soluble in alcohol but readily soluble in ether, and which melt at 144° F. Varieties of tri-palmitin are said to exist, however, which melt at 115° F. Chemically, tri-palmitin is a compound of palmitic acid, $C_{15}H_{31}.COOH$, with glycerin, $C_3H_5(OH)_3$; three molecules of the acid being combined with one of the glycerin, as indicated by the equation $3C_{15}H_{31}.COOH + C_3H_5(OH)_3 = 3H_2O + C_3H_5(C_{15}H_{31}.COO)_3$, the last formula on the right-hand side of the equality sign being that

of tri-palmitin. Two other compounds of palmitic acid with glycerin are also known, but they are of less importance. Mono-palmitin has the formula $C_5H_5(OH)_2(C_{15}H_{31}.COO)_1$, and melts at about 140° F. It may be distilled in a vacuum, but when heated in the air it breaks up with the formation of acrolein and other products. Di-palmitin has the formula $C_5H_5(OH)(C_{15}H_{31}.COO)_2$, and its melting point is given, by various authorities, at from 125° F. to 140° F. When a mixture of glycerin and palmitic acid is heated for 24 hours at 400° F., all three of the palmitins are formed; and when the product is shaken with lime water, and then extracted with ether, and the ethereal solution is evaporated, tri-palmitin, di-palmitin and mono-palmitin separate out in the order named. The palmitins are readily saponified by heating with caustic alkalis, and free palmitic acid may be conveniently prepared by adding hydrochloric acid to an aqueous solution of potassium palmitate.

PALMS, trees or shrubs of the monocotyledonous family *Palmaceæ*, ranking in economic importance next to the grasses. The species, of which about 1,000 are recognized, belong to about 130 genera. The great majority of these genera consist of only a few species, in many cases of only one. *Calamus* (the rattan palms) is the largest genus, consisting of about 200 mostly Asiatic species with no representatives in the Western hemisphere. *Geonoma* and *Bactris*, American genera, each contain about 100 species. Another American genus, *Chamadorea*, has about 60 species. The Asiatic and Australasian genus, *Licuala*, contains about 30 species. *Cocos*, an American genus with the exception of the cocoanut, which is cosmopolitan within the tropics, also contains about 30 species. *Desmoncus* (American), *Pinanga* and *Areca* (Oriental) each contain about 25 species. Geologists and botanists are fairly well agreed that the palms represent a once more extensively distributed and more numerous group of plants and that they are now upon the decline. Fossil remains are preserved in the rocks of the Middle Cretaceous, and, in North America, in those of the Upper Cretaceous from Greenland southward; in both Europe and North America they are also found in the Tertiary rocks.

With few exceptions the individual genera and even the tribes which they comprise are restricted in their distribution; certain tribes are African, others Asiatic or American, etc., and certain genera are found in very small areas; for instance, *Pseudophœnix sargenti* is found only in certain of the Florida Keys and even there in limited numbers, and the species of *Howea* only in Lord Howe's Island, a tiny speck of land in the southern Pacific Ocean. Only one species (*Chamarops humilis*) is an acknowledged native of Europe. The most noted exception to this rule is the cocoanut palm (*Cocos nucifera*) which appears throughout the tropics upon maritime land. It is among the first plants to obtain a foothold upon newly-formed islands. As a group, the palms are almost restricted to tropical and subtropical countries; the European species mentioned, however, extends as far north as latitude 44°; an American species, the palmetto (*Sabal palmetto*), to 35°; some Asiatic species to 34°. In the Southern hemisphere some American species reach latitude 36° S., some African

30° S. In Australia, latitude 35° S. is the limit; but in New Zealand one species reaches 38° S. There are, however, a few South American species which approach the perpetual snow line upon the mountains. With respect to habitat, the various species exhibit a wide range of adaptability, some, like the cocoanut, growing upon the sea coast, others wholly inland; some in sand, others in rich alluvial soils; some in swamps, others on dry hillsides; some in exposed places, others in the depths of the forest; some solitary, some in groups, some in forests or jungles to the exclusion of other trees.

In general, palms are erect, unbranched trees with buttressed bases. They often attain heights of 100 feet and at the summits of the usually smooth or slightly ringed columns they bear a rosette of large leaves each of which resembles in some kinds a fan and in others a feather. In some species of the latter type the leaves may exceed 40 feet in length and six feet in breadth. There are, however, exceptions to the ordinary columnar habit of growth; a few species are branching; some are low growing, even creeping; others are slender stemmed plants which climb by means of hooked spines; some have flexible stems which extend from tree to tree in festoons and attain several hundred feet, 500 feet being common, and some writers placing the length at 1,500 and even more. In the ordinary species the flowers are borne in huge clusters which appear from within spathes that open in some cases with a report. The fruits are of various kinds, berries and drupes being perhaps most common. They are often enclosed in a fibrous husk, and frequently contain a hard nut. The flowers, which are generally small and individually inconspicuous, bear no relation in size to the fruit, which may be as small as a pea or, as in the double cocoanut, larger than a man's head.

While the grasses are of widest economic importance among plants the palms are employed for the largest number of purposes. All parts of the various species are used, but in few do more than two or three parts find extensive employment. Many palms furnish good fuel, some useful timber, others masts and spars. The pith of certain species, especially of *Metroxylon* and *Caryota* supplies sago. The thin, pliant stems of many species of *Calamus*, known commercially as rattan, are widely used throughout the world for wickerwork and furniture. The terminal bud of several kinds is cooked and eaten like cabbage, such species being known as "cabbage palms"—for instance, *Euterpe oleracea*. The leaves serve for thatching houses, and as material for walls, mats, screens, shields, clothing, hats, bedding, cordage, twine, nets, etc. The spines of certain species are used for tipping arrows and spears, for tattooing, for fish-hooks, etc. The fibre of the leaves of many species seems to offer useful paper-stock; that of others, for example, the piassaba fibre, derived from various species of *Attalea* (especially *A. funifera*) is extensively used for brushes of various kinds, ranging from hair-brushes to stable brooms and street-cleaning machines. The sap of several species is used for the manufacture of palm-wine and of arrack, the latter a spirituous liquor; it is also employed in making jaggery, a kind of sugar of some commercial importance.

For this latter purpose *Phoenix sylvestris* is perhaps the principal species. In some cases the sap is obtained by tapping; in others by cutting the terminal bud or even the trunk near the base.

The fruits of many species are useful. As food the coconut and the date are probably the most widely known and important. The former is employed not only as a fruit, but its contained liquid or "milk" furnishes a palatable drink either fresh or prepared as a wine. The kernel supplies the "shredded coconut" employed in confectionery, cakes and puddings. It also yields coconut butter or oil. The fibre of the husk is widely used for matting and is very popular where great durability is essential, as upon the aisles of public halls. The shells make serviceable dippers, bowls and other utensils, or when carved and polished, attractive ornaments. The date palm supplies the Arab and other peoples of northern Africa and southern Asia with one of their chief foods, for which purpose it is commonly seen near dwellings, besides being planted extensively for commercial purposes. The chief commercial supplies come from Arabia, Persia and Mediterranean Africa.

Oils are obtained from the fruits of a large number of species, especially *Elais guineensis*. Some of these oils are used for food, others for lubricating; some for illuminating; and others for soap and candle making. Usually these oils are orange-colored, violet-scented and sweetish. They are generally obtained by boiling the ripe fruits in water, though also frequently by expression. Like butter, they soon become rancid unless kept cold. Palm butter is a popular name for several of the kinds. A palm wax is secured from species of *Copernicia*, and is used like beeswax.

The seeds of many species are very hard and are used for manufacturing small ornamental and useful articles such as knife handles, collar buttons, etc. Probably the best known of these is the so-called "vegetable ivory" (q.v.) which is derived from the *Phytelephas macrocarpa*, a South American species with a short or even creeping stem, from which arise pinnate leaves often more than 15 feet long. The seeds of *Areca catechu* are mixed with lime and pepper leaves to make the notorious "betelnut" (see BETEL) of eastern Asia. The product is used as a stimulant.

The most remarkable palm of all is perhaps the palmyra, deleb or barossus palm (*Borassus flabellifer*). This species is a native of southern Asia, the Australasian Archipelago, and western Africa, where it sometimes exceeds 100 feet in height. The leaves, which often exceed three feet in length, have spiny-margined petioles; the triangular fruits are about five inches in diameter, have a brownish or black, glossy, succulent, fibrous rind, and contain three seeds about as large as goose-eggs. Throughout India this is the commonest palm, and in Ceylon it occurs in extensive forests. It is employed for more purposes than perhaps any other plant, upward of 800 uses being recorded for its various parts. Its wood, palmyra wood, is heavy, dark, hard, durable, easily polished, difficult to cut across the grain but easy to cut with the grain. It is used for house-building, furniture, etc. The wood of some other palms is also known by this name and as porcupine-wood. The leaf stalks make excellent fences. The leaves are

employed for thatch, mats, umbrellas, fans, hats, baskets, as writing tablets, for ropes, twine, etc.; the down at the leaf-bases for lint and for filtering liquids; the sap yields sugar, palm wine and arrack; the fruit is cooked as an esculent; the young seeds are similarly employed, and the young plants serve as pot-herbs. A large part of the population of southern India depends upon this plant to supply its needs—fuel, shelter, clothing, food, etc.

Among the most important palms the following with their chief uses may be mentioned: Assai or Para palm (*Euterpe edulis*), a South American species whose fruits are macerated in water to make a popular drink called assai; Bourbon palm, one of the most widely grown of greenhouse and house palms, usually called *Latania borbonica* by florists, but properly *Latania commersonii*: double Seychelles, or sea-coconut palm (*Lodoicea callipyge*), chiefly noted for its great size, slow growth, enormous seeds weighing more than 10 pounds (even, it is said, more than 30 pounds), which from their seeming malformation but more particularly from their formerly unknown origin, gave rise to numerous fabulous tales; curly palm (*Howea belmoriana*), one of the best-known greenhouse palms, and popularly called *Kentia belmoriana*; fan-palm, any species with fan-like leaves; fern-palm (*Cycas revoluta*, etc.), commonly raised in greenhouses; fish-tail, wine or toddy palm (*Caryota urens*), a source of jaggery, arrack and palm wine; flat palm (*Howea fosteriana*), a favorite greenhouse palm popularly known as *Kentia fosteriana*; raphia palm (*Raphia*), which furnishes the raphia used by florists and nurserymen for tying up plants; Royal palm (*Oreodoxa regia*), so named in expression of its majestic appearance, and one of the most popular avenue-palms of warm countries; umbrella palm (*Hedyscopia canterburiana*); walking-stick palm (*Bacalaria monostachya*); wine palm (*Caryota urens*; *Phoenix sylvestris*; *Borassus flabelliformis*, and *Cocos butyracea*); gomuto or areng palm (*Arenga saccharifera*), which furnishes fibre used for cordage, canvas, etc., and sugar, wine, vinegar, etc.; inaja palm (*Maximiliana regia*), the spathes of which are used as baskets and as cooking utensils; doum palm (*Hyphena thebaica*), one of the few branching palms; talipot palm (*Corypha umbraculifera*), noted for its prodigious fertility in flowers, the number of blossoms upon a single tree having been estimated at 60,000,000, the inflorescence attaining a height of 30 feet above the crown of leaves. The "palm" of the Bible is believed to be the date-palm, which is one of the commonest species in Syria at the present time. The so-called Panama-hat palm (*Carludovica palmata*) is not a palm botanically, but a member of the family *Cyclanthaceae*.

With the exception of the date and the coconut, palms are little cultivated, the wild species being relied upon for commercial purposes. Even these species and those used for sugar, arrack, etc., are usually planted in favorable situations and allowed to shift for themselves after once becoming established or even before. For ornamental purposes, however, more or less care is given the young trees used in warm climates for bordering avenues, and as lawn or garden specimens.

During the closing decade of the 19th century palms sprang into popularity as greenhouse

and house plants, for which purposes, and for decorating halls, churches, hotels, lobbies, etc., about a dozen species have become deservedly popular, not only because of their graceful appearance, but because of their ease of cultivation. Many other species are also found in private conservatories. In the United States the chief centre of palm production for these purposes is the Middle Western States, but the South is also increasing its area devoted to ornamental palms. The plants are nearly all grown from imported seeds sown in warm greenhouses. In some cases the seeds require months or even more than a year to germinate; but usually a month or two is sufficient. In many cases the young seedlings resemble one another, whether they will develop into pinnate-leaved or fan-leaved specimens. At all times ample water and good drainage are essential; shading is also generally beneficial. The plants generally succeed best in well-rotted sod obtained from rather light soil rich in humus. Scale-insects and the red spider are the chief enemies; the former may be controlled with kerosene emulsion (see FUNGICIDE); the latter by forcible spraying, moist atmosphere and by evaporated (not burned) sulphur. The fumes of burning sulphur are fatal to the plants.

Crop Expert.

PALMYRA, pāl-mī'ra, Arab Dominions, the Hebrew *Tadmor*, City of Palms, an ancient city of Syria, now in ruins, 140 miles east-northeast of Damascus, lat. 34° 24' N., long. 38° 20' E. It was founded or enlarged by Solomon in the 10th century B.C. It is situated in an oasis of the Syrian Desert, with a ridge of hills to the west and an extensive plain on the east. It is said to have been a bulwark of the kingdom of Israel against the wandering tribes of the desert, and was an entrepôt for the trade between Damascus and the Mediterranean, from which it drew considerable wealth. Palmyra was little heard of in history until the time of the Roman Empire. It is mentioned as having been attacked by Mark Antony, who hoped to find in it the means to pay his troops; but the Palmyrians transported their goods beyond the Euphrates, and he was compelled to leave without accomplishing his object. During the earlier period of the empire it was independent, and carried on a considerable trade with Persia, India and the Mediterranean. Subsequently, about 130, or according to other authorities later, it submitted to Rome, and became a Roman colony. The protection of Rome against its neighbors, the Parthians and the Persians, was of value, while the yoke of so distant a mistress was not heavy. It became the faithful ally of Rome in her wars against the Eastern powers. During the reign of Gallienus (260-68), Odenathus, the ruler of Palmyra, rendered such effectual assistance against the Persians that that emperor gave him the title of Augustus and recognized him as his colleague. Odenathus was succeeded by his widow, Zenobia, to whom Palmyra chiefly owes its fame, and who took the title of Queen of the East.

She was besieged in Palmyra by Aurelian and compelled to surrender. On his departure the Palmyrians revolted, on which Aurelian returned and destroyed the city (273 A.D.). He permitted the inhabitants to rebuild it, but it never recovered its importance. The remains of Palmyra are chiefly of the Corinthian order, with the exception of the temple of the Sun, which is Ionic. They are supposed to belong to the period of Odenathus and Zenobia. (See ZENOBIAN). Consult Wright, 'An Account of Palmyra and Zenobia' (1895).

PALMYRA, Mo., city, county-seat of Marion County, on branches of the Chicago, Burlington and Quincy Railroad, about 14 miles northwest of Hannibal and five miles west of the Mississippi River. It was settled in 1818, laid out in 1819 and incorporated in 1855. It is in a farming country and the chief manufactures are connected with farm products. It has a pickle factory, creamery, flour and grist mill and a carriage factory. The educational institutions are Centenary High School (M. E. South), founded in 1884, and the Saint Paul's College (P. E.), founded in 1848 as the Ingleside Female College, and public and parish schools. Pop. 1,964.

PALMYRA WOOD. See PALMS.

PALNI (pāl'nē) **HILLS**, mountain range of southern India, joining the Eastern and Western Ghats, in the district of Madura, Madras presidency. The soil is fairly fertile and affords excellent pasturage. The climate is equable, comparatively dry and healthy, and there is a sanatorium at Kodikanal, 47 miles northeast of Madura.

PALO, pā'lō, Philippines, a pueblo of the island of Leyte, situated on the northeast coast at the mouth of the Malo Malo River, six miles south of Tacloban. It is an important road centre, being connected by road with Tacloban and other important towns to the south and west. Pop. 17,740.

PALO ALTO, pā'lō āl'tō, Cal., town in Santa Clara County, on the coast division of the Southern Pacific Railroad, 33 miles southeast of San Francisco and 18 miles northwest of San José. It was settled in 1891 by the opening of the Leland Stanford Jr. University (q.v.) which is located here. In 1892 a number of people established homes in Palo Alto on account of the university. It was incorporated in 1894. Palo Alto is a "university town," with but few industrial establishments. The planing mills have about 30 employees, and there are stores sufficient to supply a limited amount of the local needs. There are eight churches, a high school, elementary graded schools, Manzanita Hall, a preparatory school for boys and two preparatory schools for girls. The one bank has a capital of \$100,000. The town is governed by a board of five trustees. The town owns the water and electric-light plants and has a good sewerage system. Pop. (1920) 5,900.

PALO ALTO, Tex., the name of a plain, or field, eight miles northeast of Brownsville (q.v.), Cameron County, where was fought, 8 May 1846, the first important battle of the war between the United States and Mexico. Gen-

eral Taylor with 2,000 United States troops was on the Rio Grande opposite Matamoras; and General Arista with a force of 6,000 Mexicans tried to cut him off from Point Isabel which was the base of United States supplies. Taylor attacked and defeated Arista; the Mexicans retreated to Resaca de la Palma. The United States loss was nine killed and 44 wounded, two missing; the Mexicans, 102 killed and 128 wounded. Consult Howard, 'General Taylor' (1892); Bancroft, 'History of Mexico,' (Vol. V).

PALOLO, an annelid (of the genus *Eunice viridis*) found in great abundance in the sea near the coral reefs of tropical islands. They are taken in large numbers in autumn in nets by the islanders, who esteem them, when roasted, as a great delicacy. The body, about a foot long on the average, tapers toward both ends, and along each side are tufts of gills. An American species (*E. fucata*) abounds in various parts of the West Indies and Gulf of Mexico, but is not eaten.

These worms are interesting mainly on account of their extraordinary breeding habits. During the most of the year the worms lie coiled up in burrows in rotten coral-rock, or other friable material. When the eggs have ripened within the body, and the time for their discharge has come (which happens in early November in the south Pacific, and in July in the West Indies), the hinder part of the worm, which contains the ovaries and sexual organs, creeps backward out of the burrow, and struggles to get away, while the forward vital part holds on to its burrow. This takes place simultaneously with all the millions of worms in a district. After a little struggle the posterior part breaks away and swims with great rapidity to the surface, vast swarms rushing together to the top, where they are devoured by fishes and birds, and in the South Seas are netted by men, women and children, by the thousand. Almost at once each worm bursts, discharging the eggs in a shower, and when all are gone the worm ceases its backward flight, collapses and dies. On no other occasion is the worm seen to leave its submarine burrow.

PALOS, pā-lōs', Spain, a former important seaport town of Andalusia, in the province and 10 miles southeast of Huelva, on the left bank of the Rio Tinto, near the Gulf of Cadiz, where Columbus fitted out his ships, and whence he sailed on his first voyage for the discovery of the New World in 1492. The convent at the gate of which Columbus appeared as a poor stranger, and asked bread and water for his child, is still standing here. Palos is now an unimportant village.

PALPI, the organs or appendages, consisting of stalked or jointed processes, found in connection with the mouth of many invertebrate animals, and which appear to be chiefly devoted to the exercise of the sense of touch, the means by which the animal explores the surface upon which it walks, and probably in some cases of taste also. Thus, in many insects palpi are borne by the "maxillæ" or lesser pair of jaws (*maxillary palpi*), and by the "labium" or lower lip (*labial palpi*). The labial palpi in butterflies form the cushion-like organs by which the elongated proboscis or tongue is protected when at rest; and the small maxillary palpi of these

insects are sometimes known as *palpuli*. In bees, etc., the labial palpi are of great relative length. In *Arachnida* (spiders, scorpions, mites, etc.) the maxillary palpi are largely developed. In the spiders these organs in the males are concerned in reproduction, and in the females they are terminated by hooked claws. In the scorpion the same structure forms powerful nipping-claws or *chela*. In the higher crustaceans (lobsters, crabs, etc.) certain of the jaws bear palpi. Consult Packard, 'Zoology' (1897).

PALPITATION, abnormal movement or beating of the heart, sometimes violent and spasmodic; sensible to the patient and causing discomfort or distress. Its immediate mechanics is an over-stimulation of the excitability of the muscular structures of the heart, due to disturbed action of the nerve structures which regulate its movements. The predisposing and exciting causes of palpitation are numerous; for example, an excitable temperament; bodily and mental exhaustion; inanition; deterioration of the blood as in scurvy, chlorosis and spanæmia; violent exercise or emotion; mental shock; dissipation; dyspepsia. Tobacco and alcohol by their poisonous action also cause palpitation. Disorders of the sexual apparatus in women is frequently accompanied by palpitation, which is common in youth and middle life, especially among those engaged in sedentary occupations. In short, whatever tends to disturb the orderly action of the nervous system may induce palpitation, which is sometimes accompanied by symptoms of choking (*globus hystericus*), vertigo, ringing in the ears, impaired vision, partial unconsciousness, a clammy coldness of the extremities and the fear of death, due to general nervous agitation. When palpitation arises from actual or organic disease of the heart it is sometimes spoken of as symptomatic; when due merely to disturbed action of the heart or to disorders elsewhere it is frequently called functional, though it is always but a symptom. When occurring with organic disease it often causes more anxiety to the patient than the disease itself. The heart's action is constantly being balanced by the two nervous systems, the sympathetic, overaction of which causes increase in its rate of contraction; and the autonomic, overaction of which causes a slowing. Thus an over sympathetic stimulation—as occurs in many hyperthyroid states for example—or an under autonomic action, as in any paresis of the vagus, will cause a tachycardia. In treatment, remove as far as possible the exciting cause, enjoin absolute rest, keep the feet warm, sometimes give hot drinks—milk, cocoa and hot water containing a little baking-soda are useful. Valerian and aromatic spirits of ammonia are often valuable. Severe cases should be under the care of a physician. Consult Bayliss, 'General Physiology'; Higier, 'Vegetative Nervous System' (in *Nervous and Mental Disease Monograph Series*).

PALSY. See PARALYSIS.

PALTSITS, pal'sits, Victor Hugo, American historian: b. New York, 12 July 1867. He was educated in public and private schools, Cooper Union and Columbia University. From 1888 to 1907 he was connected with the Lenox Library, New York, was State historian from 1907 to 1911 and since 1914 has been keeper of

manuscripts at the New York Public Library, where since 1915 he also has had charge of exhibitions and since 1916 has held in addition the post of chief of the division of American history. Mr. Paltsits has edited several volumes of documents and has written 'Bibliography of the Works of Philip Freneau' (1903); 'Bibliography of the Works of Father Louis Hennepin' (1903); 'Lewis and Clark Bibliography for Original Journals of Lewis and Clark' (1904); 'Bibliography of the Writings of Baron Lahontan' (1905); 'Scheme for the Conquest of Canada in 1746' (1905); 'The Almanacs of Roger Sherman, 1750-61' (1907); 'The Manuscript Division of the New York Public Library' (1915).

PALUDAMENTUM, a white cloak, which the commander of the Roman army put on in time of war. Sometimes, however, the color may have been crimson, and in the case of the emperor himself it was purple.

PALUDAN-MÜLLER, päl'oo-dän-mül'lër, **Frederik**, Danish poet; b. Kjørteminde, on the island of Funen, 7 Feb. 1809; d. Copenhagen, 29 Dec. 1876. In 1828 he entered the University of Copenhagen and while a law-student there attracted attention by his poem 'Raab til Polen' (1831) and a drama 'Kjarlighed ved Hoffet' ('Love at Court') (1832). His first poem of note was 'Dandserinden' (1833), followed in 1834 by the lyric drama 'Amor og Psyche' and by two volumes of 'Poesier' (1836-38). His later works include 'Venus' (1841, a dramatic poem); 'Dryadens Bryllup' (1844); 'Tithon' (1844); 'Tre Digte' (1854), among them the lyric drama based on the life of the Indian sage 'Kalanus'; 'Nye Digte' (1861); and the two prose works, 'Üngdomskilden' ('The Fountain of Youth') (1865); and 'Ivar Lykkes Historie' (1866-73), a novel. His chief work is 'Adam Homo,' a poem in *ottava rima*. An edition of his poems in eight volumes appeared in 1878-79. See **ADAM HOMO**.

PALUDISM (Lat. *palus*, *palud-*, a marsh), malarial poisoning; disease or disposition arising from malaria (q.v.).

PAMBAN-MANCHE, or **SERPENT BOAT**, the native name for a long canoe used on the Malabar coast. They are from 30 to 60 feet in length, not more than three feet in beam and are hollowed out of a single tree. The largest are rowed by about 20 men, double-banked, and can attain a speed of 12 miles an hour.

PAMELA, pä-mē'la, or **VIRTUE REWARDED**, a novel by Samuel Richardson, published 1741-42. It was the first work of its author, who began what is called the modern analytic novel. It won instant applause and a wide circle of readers, all classes of society following with close attention the shifting fortunes of Pamela Andrews, a serving-maid whom the son and heir of the family dishonorably pursues. Richardson created a new era in fiction when he chose a girl of the humble class for heroine, and made use of every-day contemporaneous persons and scenes of the purposes of the novelist. Thus the story of incident and the analysis of character came into English fiction, and thus the modern novel traces its development from Richardson. It was satirized and parodied in 'Joseph Andrews' by Fielding.

PAMIR (pä-mēr') **PLATEAU**, **The**, or **THE PAMIRS**, West-Central Asia, an elevated region described as a "huge boss or knot," north of the Hindu-Kush Mountains, connecting the Himalayan and Thian-Shan mountain systems. (See **HIMALAYA**). The plateau is about 150 miles long by 150 miles broad, nine-tenths of the area being mountainous and the rest pasture-land. The name applied to the valleys is derived from the Persian *pai* and *mir*, signifying "the foot of mountain peaks"; the region is called also by the Persians *Bām-i-dunyā* ("the roof of the world"). The territories belonging to Russia, China, Afghanistan and Britain meet in the Pamir region, and until the completion of the Anglo-Russian surveys in 1895 demonstrated its strategic valuelessness, owing to climate and physical conditions, it was a fertile source of political dispute. The plateau has a general elevation of more than 13,000 feet, dominated by still loftier ridges and summits attaining a maximum altitude of 25,800 feet in Mustagh-ata, in the Sarikol range, and covered with perpetual snow. On the plateau are several small lakes, and the sources of the Oxus. From November to April the Pamirs are snow-bound and practically inaccessible, while in the spring and summer the high winds make traveling very unpleasant. The great part of the surface is bare and barren; the native Kirghiz, however, find a certain amount of pasture for their cattle in summer, and in favored localities there is some cultivation. The "roof of the world" is celebrated throughout central Asia, and notwithstanding its physical drawbacks, two recognized trade routes have traversed it east to west for ages.

PAMLICO, pä-m-lē'kō, a so-called river in North Carolina, really an estuary of Tar River, opening into Pamlico Sound. It is 40 miles long, from one to eight miles wide and navigable for steamers which can enter the sound. Several small streams flow into the Pamlico River.

PAMLICO, a sound or lagoon on the coast of North Carolina, the largest lagoon on the east coast of the United States. It is about 80 miles long and from 15 to 30 miles wide. It is separated from the Atlantic Ocean by long, narrow, sandy islands—bars or beaches—the point farthest out being the famous Cape Hatteras. Pamlico and Neuse rivers or estuaries enter the sound, and the outlets on the east are Hatteras and Ocracoke inlets. The northern part is shallow, connecting through Croatan Sound with Albermarle Sound; the central and southern area has a depth of 21 feet or more. Fish, oysters and wild fowl are abundant. Several small islands skirt the shore; Roanoke, at the northern extremity of the sound, is the largest.

PAMLICO INDIANS, a former American tribe living on the Pamlico River in Beaufort County, N. C. They were greatly reduced in number by the smallpox in 1697, and were practically exterminated by the Tuscarora War in 1711.

PAMPA, pä-m'pä, or **BAMBA**, a Quichua word meaning "plain," applied to various great plains in South America, and also occurring in proper names, for example, Riobamba, Moyobamba, Ayapampa ("Plain of Death"), and

Cochabamba ("Lake Plain"). Rarely, as in Peru along the Ucayali River, forested plains are spoken of as pampas; the typical pampas are stretches of treeless plain, varied with rolling prairie, their vegetation being annual or perennial herbaceous plants, with a few shrubs. Water courses are absent, but there are many lakes or pools of rather brackish water. The predominance of grasses, especially varieties of the cereals, make the pampas in general an ideal feeding ground for steers, horses and sheep. A marked botanical feature of the pampas is a huge thistle apparently indigenous to the Northern hemisphere.

In common usage pampa or the pampas is confined to a great plain in Argentina, the administrative district of Pampa Central, with General Acha as capital. Here to a certain degree the original nature of the vegetation has been altered by tree planting, so that much of the plain, which many years ago was opened up for cattle grazing by Roca's successful expedition against the Indians of this region, now no longer grows the *pasto amargo*, but only grasses better suited for sheep. These are tended by *Gauchos*, Spanish and Indian half-breeds. The pampas have been scientifically studied by d'Orbigny, Darwin and Roth. Beneath a layer of thin vegetable mold, there is 40 or 50 yards of reddish clay, with an admixture of fine sand of chalky infiltrations, apparently proving repeated inundations in geological time. There is a rich prehistoric fauna, notably remains of *machærodus*, *hippidimus*, *mylodon*, *megatherium* and mastodons; in the whitish lacustrine deposits near the surface fragments of terra-cotta and primitive tools, as well as bones (some of prehistoric animals), engraved and polished by man.

PAMPA AULLAGAS, owl-yä'gäs, or POPOO. See AULLAGAS.

PAMPANGA, pä-m-pän'gä, Philippines, a province of the island of Luzon, situated in the southwestern part of the island, bounded on the north by Tárlac, on the east by Bulacán, on the south by the Bay of Manila and on the west by Zambales; length, $37\frac{1}{2}$ miles from north to south; greatest width, 34 miles; area, 2,209 square miles. The province is high in the north and mountainous in the northwest and west but low and marshy in the south; along the shore of Manila Bay and for several miles inland the country is covered by canals and the estuaries of the Grande de la Pampanga River. The principal products are rice (raised in the lowlands of the south), sugar, sweet potatoes, gabe, tobacco and cotton. Agriculture is the chief occupation of the inhabitants, but mechanical industries are also quite extensively developed; the most important are weaving and the manufacture of sugar, the fisheries of Pampanga are increasing in importance, and there is a large local trade in nipa, sugar, honey, sacks, etc. There are roads connecting all the towns, and connecting the province with Manila, Cavité, Tárlac and Nueva Ecija; the Manila and Dagupan Railroad crosses the province from southeast to northwest, passing through the larger towns, and has been an important factor in the industrial development of the province. The great majority of the people are Pampangos (q.v.). Civil government was established in the province in February 1901. Pop. 224,000.

PAMPANGA, Rio Grande de la, rē'ō grän'dä dä lä pä-m-pän'gä, one of the four great rivers of Luzon, Philippines, is formed in the northern part of Nueva Ecija by the junction of a number of streams that drain the western slopes of the Caraballos Sur, flows southwest and south through the province of Nueva Ecija and Pampanga and empties into Manila Bay through a delta of eight mouths. It drains a large territory, and has numerous tributaries, chief among them the Rio Chico de la Pampanga; in the rainy season it overflows its banks in the lower part of its course, and these inundations make fertile soil for the cultivation of rice. It is about 120 miles long, and the means of a large local trade.

PAMPANGOS, a group of tribes of the Philippine Islands inhabiting the province of Pampanga, Luzon and single localities in Nueva Ecija, Bataán and Zambales. They are of the Malay race, and at the time of the Spanish conquest of the islands had a civilization and writing of their own. In Pampanga they use their own language, which is spoken exclusively in that province.

PAMPAS, pä-m'paz (Sp. pä-m'päs). See PAMPA.

PAMPAS CAT. The grass, straw or wildcat (*Felis pajero*) of South America, common on the grassy plains. Hudson, in 'A Naturalist in La Plata' (1892), describes it as not unlike the European wildcat in its robust form and dark color, "but a longer, more powerful animal, inexpressibly savage in disposition."

PAMPAS DEER, a small deer (*Cervus campestris*) of the plains of southern South America, having antlers of three points each.

PAMPAS GRASS, the most beautiful and the most important commercial ornamental grass (*Cortaderia argentea*). It is a native not of the pampas of South America, but of the well-watered higher lands of Brazil and Argentina. It grows in large clumps, has leaves often more than six feet long, and flowering stems frequently exceeding 10 feet in height, surmounted by great graceful plumes (panicles) of silvery-white flowers which may be more than two feet long. This beautiful plant is grown in large quantities in California and sold for use in decoration, the plumes often being dyed with aniline in various tints. Outside of California, which is the only country where this grass is grown for market, the plants are cultivated for ornament in parks and gardens, but in the north they need protection with leaves or litter during the winter. They will grow in any good garden soil with no special attention. There are several horticultural varieties whose flowers are pink, carmine, purple and intermediate tints. Two related species are of some importance; uva grass (*C. saccharoides*), a native of Brazil, furnishes considerable sugar, and *C. jubata*, a plant even more graceful than the pampas grass. Neither is grown in the United States, the former being very tender and the latter little known.

PAMPAS DEL SACRAMENTO, pä-m'päs dël säk-rä-mën'tō, Peru, great plain in the northeastern part of the republic, between the Ucayali and Aullaga (or Huallaga) rivers; area, 60,000 square miles. It is crossed by ex-

cellent waterways, has a rich vegetation and was settled in the 18th century by Jesuit missionaries, but is now almost deserted.

PAMPELUNA, pām-pā-loo'nā, or **PAMPELUNE**, pānp-lün, variant spellings of Pamplona (q.v.).

PAMPILUS, pām'fi-lūs, Greek painter: b. between 390 and 350 B.C. He and Eupompus were the founders of the Sicyonian school of painting. He was the teacher of Apelles and Melanthus and was famous for scientific accuracy in drawing and perspective. He made his pupils pay him a talent (about \$2,000) for a course in painting. Among his works famous in antiquity were 'The Battle of Phlius'; 'The Voyage of Ulysses' and 'Family Group.'

PAMPILUS, Saint, a priest of Caesarea, by birth a Phœnician, who for refusing to sacrifice to idols was cast into prison. He was a theological teacher at the famous catechetical school at Alexandria and collaborated with Eusebius in writing 'The Apology for Origen.' Persisting in adherence to the Christian faith, he was condemned to death (309) and suffered martyrdom by decapitation 16 February, the day on which his festival is celebrated.

PAMPHLET, a name applied to an ephemeral publication, occasional and not periodical, commonly discussing some question of public or special interest at the time. There are thus two distinct classes of pamphlets, the one addressed to the general public, and discussing some question of immediate though probably of temporary interest. Political pamphlets form the type of this class. The other is addressed to a special class of readers, and discusses something connected with their particular interests or pursuits. Pamphlets of both classes are now to a great extent superseded by the opportunities of discussion afforded by regular periodical literature. They still, however, serve many important uses. Pamphlets have at various times since the introduction of printing exercised a very important influence, especially in this country, and in general in all times of political and religious excitement pamphleteers have been both numerous and vehement. They have comprised all sorts of men from scholars and men of genius to the most vulgar and venal of partisans.

PAMPHYLIA, pām-fil'i-ā, ancient division of Asia Minor, bounded on the north by Pisidia, on the east by Cilicia, on the south by the Mediterranean (Gulf of Adalia) and on the west by Lycia. Its coast line measured 75 miles, and its extent north and south was about 30 miles. The geological formation is peculiar, the entire surface of the country having been greatly changed since classical times by continuous fluvial deposits of carbonate of lime. The region was never an independent kingdom, so far as we know, but was successively subject to Lydia, Persia, Macedonia, Pergamum and Rome. The population in early times seems to have consisted of an admixture of Semitic and Indo-Germanic elements. There were Greek settlements at Perge, Aspendus, Side, Cibra and Attalia, and remains of Pamphylian inscriptions show that the dialect of Greek used there resembled both Cyprian and Arcadian and hence was a very early form. Consult Ramsay, 'Historical Geography of Asia Minor'

(1890); Radet, 'Les villes de la Pamphylie' (1890, in *Revue Archéologique*); and Lanckoronski, 'Städte Pamphyliens und Pisidiens' (1890).

PAMPLONA, pām-plō'nā, **PAMPELUNA**, or **PAMPELUNE**, Spain, capital city of the province of Navarre, situated near the French border, 200 miles northeast of Madrid, in a plateau 1,400 feet above sea-level, on the right bank of the Arga River and on the railway from San Sebastian to Saragossa. There is an old and a new quarter. The former with its narrow streets has changed little since the city was the capital of the French kingdom of Navarre; but the new part is regularly laid out. The main objects of interest are a cathedral, begun by Charles III in 1397, the historic hall where the Cortes of Navarre used to meet, the churches of San Nicolas and San Saturnino and several fine promenades and boulevards, La Taconera being the best; nearby are the gorges of Mayo and Roncesvalles. A citadel built by Philip II has been reinforced by more modern fortifications; the city is an important point strategically. The main industries are the manufacture of leather, linens, paper, flour, soap, strings for musical instruments and wines. There is a great market at Pamplona from 29 June to 18 July. The city may have been a Roman colony, Pompeiopolis, but the derivation is not certain. It was taken from the Arabs by Charlemagne in 778, passed to Ferdinand of Aragon in 1512, was held by the French during the Peninsular War and figured in the Carlist insurrections. Pop. 30,000.

PAMUNKEY, pā-mūnk'ī, a river in Virginia, formed by the junction of the North and South Anna. It joins the Mattaponi at West Point and forms the York River. From the source of the South Anna to the York is 100 miles. The Pamunkey Indians have a reservation on the Pamunkey River.

PAMUNKEY, pā-mūnk'ī, and **TOTOPOTOMOY**, two streams in Virginia, the banks of which were the scenes of military operations during the Civil War. When General Grant withdrew from the North Anna (q.v.) on the night of 26 May 1864, he moved rapidly by the left to cross the Pamunkey, about 33 miles east. General Sheridan, with Torbert's and Gregg's cavalry divisions, preceded the infantry in the afternoon and at nine o'clock next morning had crossed the Pamunkey and occupied Hanover Town, near which place, on the Hanover Court House road, one of Gen. W. H. F. Lee's cavalry brigades was met and forced back toward Hanover Court House. On the morning of the 28th Gregg's cavalry division, advancing on the Mechanicsville road, had a severe engagement with the Confederate cavalry near Hawes' Shop (q.v.) and, aided by Custer's brigade, drove it back upon the infantry at the Totopotomoy. General Lee had early information of Grant's movements, and on the 27th put his army in motion to interpose between him and Richmond. Early's corps crossed the South Anna, and by midday of the 28th was in position with its right near Beaver Dam Creek, its left on the Totopotomoy, near Pole Green Church, four miles from Hawes' Shop. Anderson's corps formed on Early's right and covered the road from White House, on the Pamunkey, by Old Church, Bethesda

Church and Mechanicsville to Richmond. Hill's corps and Breckenridge's command extended on Early's left to near Atlee's Station, crossing the Virginia Central Railroad a mile north. On the afternoon of the 28th the Sixth and Second Union corps crossed the Pamunkey at Huntley's, four miles above Hanover Town, and took position across the Hanover Court House road at Crump's Creek, and the Fifth corps crossed at Hanover Town, the left near the Totopotomoy, an affluent of the Pamunkey, which it entered two miles below Hanover Town. The Ninth corps crossed at midnight. The Second, Fifth and Sixth corps formed a line in front of Hanover Town, 17 miles from Richmond, the Sixth on the right, the Second in the centre and Fifth on the left. At noon of the 29th Barlow's division of the Second corps advanced on the road from Hawes' Shop to Atlee's Station, small bodies of Confederate cavalry falling back before it to the other side of the Totopotomoy, where the infantry was found strongly entrenched. Warren's Fifth corps took position on the Shady Grove Church road, skirmishing with the enemy. Wright's Sixth corps moved on the right of the Second, occupying for a time Hanover Court House, and then closing in to the left, and the Ninth corps moved between the Second and Fifth, pushing out on the road to the Pole Green Church. There was incessant skirmishing during the 30th in an effort to develop the Confederate position, and late in the day Early's corps attacked Warren's Fifth corps near Bethesda Church and attempted to turn its left, but was repulsed. To relieve the pressure on Warren, Hancock at seven P.M. was ordered to attack, and Brooke's brigade carried the first line of rifle pits occupied by the Confederates. On the 31st Birney's division crossed the Totopotomoy and carried the enemy's advanced line on the right of the Richmond road. General Wilson's cavalry division moved to Hanover Junction and destroyed the railroad bridge over the North Anna, at the same time defeating the Confederate cavalry and driving it from Mechum's Creek; and Sheridan with two divisions of cavalry, was sent to occupy Cold Harbor, driving the enemy out, and was directed to maintain his position at all hazards. On 1 June Warren moved out to develop the Confederate position and found it intrenched strongly in his front, beyond clear ground, swept by artillery fire. He lost 200 killed and wounded, extended his line some distance to the left and was attacked in several places during the day and quite severely on the right just before dark. Everywhere General Grant had found General Lee confronting him in strong works, and determined again to retire from his direct advance toward Richmond and to throw his troops rapidly to the left to Cold Harbor (q.v.). This movement began on the night of 31 May, the corps moving successively from the right. Consult 'Official Records' (Vol. XXXVI); Humphrey, 'The Virginia Campaign of 1864-65'; Wather, 'History of the Second Army Corps'; The Century Company's 'Battles and Leaders of the Civil War' (Vol. IV).

E. A. CARMAN,

PAN, in Greek mythology, a rural divinity. Comparative philology, showing that the name is related to *pastor* (Latin, "shepherd"), agrees

with the results of modern mythological study, which traces its various attributes back to an original god of the flocks, so that we can credit neither the decadent explanation of his name, from the Greek word meaning "all," by his being the son of Penelope and *all* the suitors, nor agree with the Stoics who made of him a god of the universe, the ever-present spirit of nature in *all* things. It seems evident that Pan was originally a shepherd god of Arcady; indeed the figure that Arcady cuts in modern pastoral poetry seems to be due entirely to its mention in classic authors in connection with the pastoral god. Considered as a typical shepherd Pan naturally develops into hunter, fisherman and, in time, warrior; and "Panic fear" or "panic" is explicable as an extension of the unreasoning terror that seizes a flock of sheep. Another school of mythologists stress the fact that Pan was an Arcadian god, make his various rural activities merely those of the normal Arcadian and explain his warlike functions by noting that the Arcadians were often mercenaries; but this scheme fails to explain the myth of Pan's love of Selene, the moon-goddess, which is perfectly explicable if we reckon the god a shepherd who must "watch by night." The Arcadian myths of Pan's birth are many; the commonest make him son of Zeus and Callisto, or of Hermes and a daughter of Dryops and associated him closely with Dionysus. The myth and the cultus of Pan spread slowly through Greece. He was not worshipped at Athens until after the battle of Marathon, where the panic of the Persian army was accredited to him. Compare Browning's poem 'Pheidippides.' In Rome Pan was identified with Faunus or Inuus and later confused with the Satyrs, so that *Panes* and *Panisci* were spoken of; moreover his nature was sensualized somewhat, so that in early Christian times he became par excellence the god of Greek heathenism. Hence the myth of the death of Pan at Christ's birth; and hence too, because of the representation in art of Pan as a horned being half-man, half-goat, the popular picture of the devil. Earlier Greek art, it must be remembered, made of him merely a beautiful young shepherd, only occasionally giving him horns, such as were worn by other divinities of nature, notably the river-gods. Consult Wieseler, 'De Pane' (1875); Roscher, 'Ueber Selene und Verwandtes' (1890); Stuart, 'The Great God Pan' (1913).

PAN-AMERICAN CONFERENCE OR CONGRESS, a title given to the meetings of delegates from various countries of North, Central and South America to consider questions of mutual interest. A desire for the unification of the different American nations was felt as early as 1826, when the Panama Congress, then projected, failed to meet. In 1831, 1838 and 1839-40, Mexico called a meeting, but there was no response. In 1847-48, Bolivia, Chile, Ecuador, New Granada and Peru sent delegates to a meeting, but they adjourned without effective results. Another fruitless meeting was held at Santiago in 1856, Peru, Chile and Ecuador being represented. In 1846 Peru called a conference at which eight republics met to organize a Latin-American Union and "to organize into one family the former Spanish colonies." No report was made of this

meeting. In 1878 still another meeting was held without results. In 1881 invitations were issued by James G. Blaine, then Secretary of State of the United States, for a Latin-American Congress to be held in Washington the following year, but the project was abandoned. In 1888-89 South American jurists met, but made no political recommendations. Finally, 10 May 1888, President Cleveland was authorized to call an International American Conference to meet in Washington the following year. Delegates were then present from all the governments of South and Central America except Santo Domingo. The object was the furtherance of international comity and commerce, including a customs union, sanitary regulations, intercommunication, uniform weights and measures, a common silver coin and a plan of arbitration. The only practical result was the establishment of the International Bureau of American Republics. On 22 Oct. 1901 delegates from 19 countries were present at a conference in the City of Mexico to consider arbitration, an international court of claims and the reorganization of the Bureau of American Republics. Many resolutions were adopted and the congress adjourned to meet at Rio de Janeiro, 23 July 1906. Among the subjects considered by this congress was the Drago or Calvo Doctrine forbidding governments to collect privately debts by force. Elihu Root was present and spoke of the desire of the United States to have fair and friendly relations with all other Pan-American powers. The Conference referred many points to The Hague Conference, especially the collection of international debts without recourse to arms. A number of valuable recommendations were made regarding recognition of patents, trademarks and copyrights. Municipal sanitation was also discussed at length. The fourth meeting of the Conference was held at Buenos Aires, 9 July 1910. At this time the name of the Bureau of American Republics was changed to the Pan-American Union. This bureau is supported by contributions, and Andrew Carnegie led with \$750,000 while \$250,000 was added by the 20 republics, this having been invested in a permanent house in Washington for the bureau, which has collected a large library of literature bearing on Pan-American topics. A Pan-American scientific congress has also been organized and held sessions in Chili in 1908, and Washington, D. C., in 1912. A Pan-American Commercial Congress met at Washington in 1915 and discussed ways and means for meeting the usual conditions growing out of the World War and hampering commerce in the Americas.

PAN-AMERICAN EXPOSITION, a fair held in Buffalo, N. Y., from 1 May to 1 Nov. 1901. Financially it was a failure, due largely to President McKinley's assassination, which caused a temporary closing. The total cost of the exposition was \$8,860,757.20; the total receipts \$5,478,589.37. See EXPOSITION, INDUSTRIAL.

PAN-AMERICAN UNION. The official international organization of the 21 independent republics of North and South America maintained by them in Washington for the development of commerce and trade, intercourse and good understanding and the pres-

ervation of friendship and peace among them. It is controlled by a governing board composed of the Secretary of State of the United States, who is chairman ex-officio, and the diplomatic representatives in Washington of the other American republics. It is administered by a director-general, who is elected by this board, and is, therefore, an international officer. He, in turn, is assisted by a large, trained expert and clerical staff who compile information, make research investigations, prepare reports and publications, answer inquiries, receive visitors and conduct correspondence. The Pan-American Union occupies a building on 17th street, between B and C streets near the entrance to Potomac Park in Washington, which has been described by a great French architect as "combining beauty of architecture, nobility of expression and practical usefulness more than any other official structure in the United States." It has sometimes been described as the Capitol of the Western Hemisphere in the Capital of the United States. Erected through the munificence of Andrew Carnegie and the contributions of all the American republics, it stands as a beautiful and useful monument to the cause of Pan-American solidarity and relationship.

In its practical work of spreading accurate information about the American republics and making them better acquainted, not only with themselves but with other countries of the world, the Pan-American Union publishes an illustrated monthly *Bulletin*, with English, Spanish, Portuguese and French editions, which is circulated all over the Americas and Europe and is an attractive record of the general progress of each American country. It also prepares, prints and distributes descriptive pamphlets of each constituent country of the Union, reports on a great variety of subjects and other data of an informative character. Last year it distributed nearly 1,000,000 pieces of printed matter relating to the American republics, but all of these were sent out in response to requests or to persons, firms and institutions interested.

One of the notable features of the Pan-American Union is the Columbus Memorial Library, the largest up-to-date collection in the world of practical Pan-Americana. This library contains nearly 45,000 volumes indexed with 150,000 cards, nearly 2,000 maps and atlases and 25,000 photographs. On the tables of its reading room can be found the principal newspapers and other publications of the Latin-American countries.

Perhaps a feature of the Pan-American Union which appeals to the interests of the world is its governing board, or international council, which makes the Pan-American Union a real league of peace among the American nations. On the first Wednesday of every month in the governing board room of the Pan-American Building, around a great oval table, with the chairs carrying the names and escutcheons of the constituent governments, there meets this council made up of the Secretary of State of the United States and the highest representatives in Washington of the other governments. From one to two hours they consider ways and means of so administering the Pan-American

Union as to develop the closest relationship among the American republics and to insure permanent peace among them. Since the reorganization of the Pan-American Union in 1907, following the Pan-American Conference held at Rio de Janeiro in 1906, there has been no war between any two American republics, and the moral influence of this council has probably prevented several wars on the American continent. It has been said that the Pan-American Union is a working league of nations which might be well described as the prototype of a World League to preserve peace.

Through the educational informative work of the Pan-American Union and the efforts of the United States and other governments, the commerce exchanged between the United States and the 20 Latin-American countries has grown in the last 12 years from approximately \$500,000,000 to \$1,750,000,000. The Pan-American Union has, moreover, devoted its energies to making the study of the Spanish and Portuguese languages and the geography, history and characteristics of the Latin-American countries popular among the educational institutions of the United States. It has tried to do a corresponding service for the United States in the Latin-American countries. It favors the movement for the exchange of college professors and students between the educational institutions of the United States and Latin-America. It regularly provides the leading newspapers of North and South America with information about the various Pan-American countries which will make them better acquainted with, and more interested in, each country. In many respects the Pan-American Union can be described not only as a great active organization for the development of commerce and cultural relations and the preservation of peace, but an international bureau of information for the Western Hemisphere. Any person seeking information of whatever character relating to Latin America will have his inquiry carefully considered and answered if he addresses the Pan-American Union, Director General, Washington, D. C.

The present executive staff of the Pan-American Union includes the following: John Barrett, director-general; Francisco J. Yánes, assistant director; Franklin J. Adams, chief clerk and editor of the *Bulletin*; W. C. Wells, chief statistician; W. A. Reid, chief trade adviser; C. E. Albes, assistant editor; V. A. Wood, chief accountant; Angel C. Rivas, Spanish translator and assistant editor; C. E. Babcock, acting librarian.

PAN-GERMANISM, a movement, originating in German imperialism and the German race-consciousness, born of the establishment of the empire, having for object the uniting of all European people of Germanic stock wherever located into one great national unit. The movement crystallized finally in the foundation of a society styled the universal German League (*Allgemeiner deutscher Verband*) on 9 April 1891. On 1 July 1894 the name was changed to the Pan-German League (*All deutscher Verband*) and at the same time was founded the official organ of the League, the *Pan-German Gazette* (*Alldeutscher Blätter*). Some persons prominent in the Pan-German movement disclaimed all ulterior motives on the part of the

League in regard to political affairs and territorial acquisitions abroad, asserting the while that the sole object of the movement was to spread a knowledge of German culture—manners, customs, social polity, etc., throughout the world. They asserted their belief that there was much in German home life, education, government, social policies, etc., that was of prime interest to the rest of the world and a knowledge of which would result in great benefits, both material and spiritual, to the human race as a whole. Others identified with the movement expressed most pronounced beliefs in regard to the ultimate destiny of the Teutonic peoples, whose culture they regarded as so superior to that of the rest of mankind that they deemed it the duty of all Germans to further its progress and extend its power abroad so that ultimately by sheer weight of its worth it might become a world culture and the world, mentally, if not politically, might become a German world. The Pan-Germans from time to time gave expression to their policies, especially in regard to a strengthening of national consciousness; they advocated determined colonial and emigration policies, and sought to safeguard German interests abroad through energetic diplomatic intervention. In 1903 the League formulated its program as follows: (1) To quicken the patriotic self-consciousness of Germans, and to offer opposition to all movements antagonistic to national development; (2) To treat and solve all questions bearing upon the bringing up of children and higher education in the Germanic sense; (3) To watch over and support all German national movements in all countries where Germans have to sustain a struggle in support of Germanism, with the object of embracing and uniting all Germans on the globe; (4) To promote an active German policy of interests in Europe and across the seas, and especially to further the colonial movement to practical results.

In the four years from 1898 to 1902 the membership of the League grew from 12,000 in 82 branches (28 outside of the homeland) to 21,924 in 217 branches. With the opening decade of the 20th century the Pan-Germans, now wielding a vast influence, began to extend their activities to the ends of the earth and to pour forth a stream of literature in the shape of books, pamphlets and newspaper articles in an effort to catch up with the Anglo-Saxon world movement launched years before. Indeed, the Pan-Germans of the more radical type early recognized in Great Britain the one great obstacle to the realization of their ideals. The latter had had the ear of the world for generations and the Germans, though late in the field, were determined to make up for lost time by intensive and sedulous propaganda.

Thus far we have dealt merely with the Pan-German movement as regards its origin, development, aims and methods. In the course of the late war popular propaganda in Allied countries charged the Pan-Germans with almost every crime and misdemeanor under the sun, and with being in accord with the ruthless policy of the Imperial German Government. Much of this had best be forgotten; it served its purpose by keeping the people keyed up to the effectual prosecution of the war and its continuance would only serve to keep alive

racial bitterness and hatred. Few previous to the war would have believed it possible that the press of all countries—both of the Entente and its opponents—could be prostituted to the degree we witnessed during the war. However, it is important here to examine the connection between the Imperial German Government and the Pan-German movement, if any such existed. Undoubtedly very many officials high in the councils of the Empire were also prominent in the Pan-German movement, but the degree to which they influenced or were influenced by the latter we are unable to determine. We have, however, the repeated assertions of the German authorities that the Pan-German movement was the work of but a very small group of the German people, and that it had at no period of its history received any official sanction.

Pan-Germanism carried on its work in the open; its aims and objects were published to the world and its literary product reviewed in the press of all countries. In Germany, itself, the movement was not widely acclaimed. It was vigorously opposed by a not inconsiderable number of men in public life and also by the Socialists, whose prominent leaders took advantage of every opportunity to denounce it as a menace to the German working class, contrived by the militaristic caste as the advance guard of their grasping imperialistic policy. In Pan-Germanism we have, therefore, a movement of a very small but very powerful group organized to further German culture, if not German domination, throughout the world. This movement was recognized and commented upon in other countries; it was opposed by influential men and by a great political party in Germany itself; it never received any recognition from the imperial German government, although at times the policies of both were identical; during the war every utterance of a German imperialist or militarist was imputed to the Pan-Germans and their coterie, perhaps more often than not erroneously, since many of such utterances were made on individual responsibility in an effort to maintain the morale of the German nation at home as well as on the fighting front. The collapse of the empire in 1918 proved the greatest setback Pan-Germanism had ever received. It saw the realization of its aims and ideals postponed indefinitely, and to the world in general the movement appeared dead. That it did not die, however, was shown by the public pronouncements of the League during the sessions of the Peace Conference, more especially soon after the terms of the peace treaty had been communicated to the representatives of the new German government. See WAR, EUROPEAN: HISTORICAL INTRODUCTION AND CHRONOLOGY.

PAN TADEUSZ (Master Thaddeus).

Under the influence of Homeric studies, but more especially of Goethe's 'Hermann und Dorothea,' Mickiewicz began to write his superb epic, 'Pan Tadeusz,' and published it in 1834. The poet intended to treat Master Thaddeus as the Polish hero whose life and love was to be a parallel to that of Hermann, hence he chose a similar name for his poem. But, as he proceeded, the sum total of Lithuanian life in the beginning of the 19th century obtruded itself upon his vision, and the title now no longer corresponded to the matter in hand. The critic Gostomski has admirably characterized 'Pan Tadeusz' as something like a musical symphony which begins with an idyllic theme, through which may be heard the harsher tones calling to battle or the plaintive notes of an elegy. These themes uniting render perfectly the essence of Lithuania. Dissonances appear, the theme grows, the martial and elegiac notes prevail. Then, as the battle theme subsides, a new melody strikes the ear. We hear the cry of despair and of a suffering soul, a mighty tragic storm approaches, and all ends with a song of overwhelming contrition. The poetic symphony ends with a superb, harmonious finale, in which the previous motives are united.

In the Middle Ages the executive branch of government was feebly developed as compared with the legal side, hence it became necessary for the winning party to make forcible inroads in order to enforce the legal decision. This state of society prevailed in Lithuania up to the 19th century, and such an inroad was called in Polish *zajazd*. Mickiewicz used the theme of an old feud between two houses and the *zajazd*, in order to depict in epic form the whole of the late Lithuanian past, and, at the end of the poem, allowed the feud to subside, the parties uniting in welcoming into Poland Napoleon, from whom salvation was expected. The critical literature of 'Pan Tadeusz' is very large. Probably the best work is W. Gostomski's 'Arcydzieło poezji polskiej A. Mickiewicza Pan Tadeusz' (Krakow 1894). In English a study may be found in Monica M. Gardner's 'Adam Mickiewicz' (London 1911, ch. 6, pp. 155-182). 'Pan Tadeusz' was translated into English (London 1885) by Miss Maud Ashurst Biggs; a new translation by Prof. George R. Noyes was published in London 1917.

LEO WIENER.

PANA, pā'na, Ill., largest city in Christian County, on the Baltimore and Ohio, the Cleveland, Cincinnati, Chicago and Saint Louis, the Illinois Central and Chicago and Eastern Illinois railroads, 32 miles southeast of Springfield. It was settled about 1845; incorporated 1867, taking its name from an Indian tribe which in earlier days inhabited this region. It is located in the fertile corn belt; corn, hay, wheat and fruit being the principal products. Underlying the region surrounding Pana is an

extensive coal field and there are numerous coal mines furnishing employment to over 1,500 miners. Its excellent railroad facilities make it an advantageous manufacturing city. There are a soda-fountain factory and wood-working establishments.

It is distinguished by having the highest altitude of any city in Illinois. It has five ward schools, one parochial school and a large township high school; a free public library; a large Y. M. C. A., Huber Memorial Hospital, a beautiful city park of 40 acres; over 14 miles of paved streets with an adequate water supply system. It has a City Court with concurrent jurisdiction to that of the Circuit Court of the county. Pana was settled in 1853 and incorporated in 1867. It has an aldermanic form of government under the general law of the State. Pop. 6,122.

PANÆTIUS *pā-nē'shī-ūs*, Rhodius, Stoic philosopher: b. Rhodes, about 180 B.C.; d. Rome, about 110 B.C. He spent most of his life in Rome disseminating the tenets of Greek and more especially of Stoic philosophy. Here he enjoyed the friendship of Lælius and the younger Scipio. He subsequently traveled extensively in the East and visited Egypt and on his return opened a Stoic school at Athens. He really belonged to the middle Stoic or Eclectic school and borrowed from Plato and Aristotle. Only fragments of his writings are extant to-day. His chief treatise was one on 'Duty,' from which Cicero in his 'De Officiis' has drawn much material. Consult Van Lynden, 'De Panætio' (1802); Schmekel, 'Die Philosophie der mittlern Stoa' (1892).

PANAMA. A country of Latin America, bounded on the north by the Caribbean Sea, on the east by Colombia, on the south by the Pacific Ocean, and on the west by Costa Rica. We find in the interior a great number of hills and mountains, a few being extinct volcanoes. These have no geological connection either with the North American Cordilleras or with the Andes. The only systematic ranges are a bit of the Costa Rica central divide, which runs over into western Panama, and on the Atlantic Coast further east the Cordillera de San Blas. The detached and irregular hills are often separated by streams, greatly subdivided, whose banks (like the hillsides and, indeed, the greater part of the country) are covered with dense tropical vegetation. The exceptions to this rule are a few treeless uplands along the Pacific side between the Costa Rica border and the Gulf of Panama. The rivers and streams are the ill-named Rio Grande and the Chagres, which have been factors in the Canal Zone problems; the Tuyra and the Bayano, in the eastern and central regions; and in the western region, where the water-parting is more distinctly marked, many rivulets that flow from the central range northward to the Caribbean or southward to the Pacific. The area of the republic was officially given in 1916 as 32,380 square miles. Of the Canal Zone (see PANAMA CANAL) the area is 474 square miles. Political aspects of the acquisition of this strip, the precise terms of the grant, etc., are examined and stated in the section *History*.

Climate.—The chief hydrographer of the Panama Canal, Mr. F. D. Willson, writes that on the Isthmus average temperatures decrease

approximately one degree Fahrenheit with every 330 feet increase in elevation. The influence of the Caribbean Sea, lying to the windward, is shown in the climate of the Atlantic Coast, which is nearly of the moist and equable oceanic type; but climatic conditions on the Pacific slope and throughout the interior exhibit many of the characteristics of the continental type because the prevailing winds over these sections blow from off the Isthmian land areas. A large percentage of the rainfall comes in the form of afternoon tropical showers, the period from 2 o'clock P.M. to 3 P.M. being the hour of heaviest rainfall as a general rule. Almost the only general storms that visit the section of the Isthmus traversed by the canal are the so-called "northers" during the period from October or November to April, inclusive. Characterized by steady winds of a velocity of 30 or more miles per hour, these "northers" may or may not be accompanied by heavy rainfall. The winds alone are usually of insufficient force to hinder navigation at the Atlantic entrance of the canal; the high waves accompanying these storms, however, were injurious to shipping interests before the breakwaters that now protect the inner bay were constructed. The average annual sea temperature is about 82° F. on the Caribbean Coast and 80° F. on the Pacific side. The absolute range on the former side is only about 12° F., while on the latter (at Balboa) the absolute range is 29° F. Hail has fallen in the Canal Zone or vicinity three times since observations were begun in 1906. Water spouts have been seen at both canal entrances. Generally speaking, the climate is unhealthy except in those places where modern sanitation methods have eliminated the causes of tropical diseases.

Seismology.—Before the occupation of the Canal Zone by the commission from the United States there had been 28 recorded earthquakes, but only one or two that can be classed as destructive—possibly the shock which occurred in 1621 and certainly that of 7 Sept. 1882. Since 1904 seismic disturbances were thought to be negligible except during the fiscal year 1913-14 and in 1915. During the former year 87 shocks were recorded at Ancón. Of these 55 or 56 were of comparatively local origin, less than 200 miles distant; 31 or 32 were tremors from shocks of remote origin. Nearly all of the local shocks appeared to originate about 115 miles southwest of Ancón Hill in Los Santos Province. Ten of these were felt generally over the Isthmus, and the shock of 28 May 1914 damaged slightly the new Administration Building at Balboa. In 1915 sharp shocks were felt on 24, 25 and 26 January and on 28 June. These did not originate in the Zone, and caused little damage there or elsewhere on the Isthmus.

Tides.—On the Pacific side the average tidal range for consecutive tides is about 12.5 feet, the maximum spring range occasionally exceeding 20 feet; but at the northern entrance to the canal the average tidal range is only about 0.9 foot, and the extreme range approximately two feet. Within and beyond this tidal area we find a coral formation of a comparatively recent date, which fringes both the Pacific and Caribbean coasts and extends inland several miles near the rivers.

Chagres River, The.— This famous river is formed by the confluence of two streams at Dos Bocas, the main stream originating among the mountains of the San Blas cordillera, where peaks 2,000 to 4,000 feet in altitude are found. Mr. Willson says that although nearly the entire country from headwaters to the neighborhood of the canal is clothed with vegetation, much of which is dense, the slopes are so precipitous and rock lies so near the surface that severe tropical rain storms cover its banks with small torrents and cascades, from time to time causing the river to rise suddenly and to discharge almost incredible volumes of water. Its drainage area before it reaches the canal is 1,320 square miles. In the upper reaches there are two cañyons, each about a mile in length, and a number of rapids. By damming its waters at Gatun, the engineers of the commission have formed the dominating feature of the Panama Canal—Gatun Lake, which has an area of 164 square miles at an elevation of about 87 feet above sea-level and contains 192.24 billion cubic feet of water.

Fortifications.— Modern defensive works are maintained only in the neighborhood of the canal. General Goethals (see *Bibliography*) writes: "In 1910 Congress voted in favor of fortifying the canal and, subsequently, of having a garrison permanently located within the Zone. These defenses consist of seacoast fortifications for the protection of the entrances against naval attack and land defenses around the locks, the most vulnerable features of the canal, against any force that might be landed from an attacking fleet for raiding purposes."

Political Divisions, Population, Cities.— The republic of Panama is divided into eight provinces as follows:

PROVINCES	Capitals	Population of Capitals
Bocas del Toro.....	Bocas del Toro.....	9,000
Coclé.....	Penonomé.....	6,000
Colón.....	Colón.....	30,000
Chiriquí.....	David.....	15,000
Herrera.....	Chitré.....	6,000
Los Santos.....	Los Santos (Las Tablas)	8,000
Panamá.....	Panamá.....	50,000
Veraguas.....	Santiago.....	7,000

The number of inhabitants was given as 450,000 in 1916. (Pan-American Union, *Latin America*, Washington 1916). The estimates for 1911 and 1912 were, respectively, 337,000 and 341,000, exclusive of the Canal Zone. In the republic as a whole the mestizos are most numerous (about 190,000 to 200,000); whites about one-fourth as many.

History.— Columbus landed on the Isthmus in 1502. Then came further exploration and in its train colonization, still in the first quarter of the 16th century. In the more flourishing days of Spanish rule in that century and the next the country in general and the city of Panama in particular enjoyed the advantages coming from the shipment of South American silver and gold. But this prosperity had so dropped at the close of the 18th century that Panama was largely isolated from Colombia and took comparatively little part in the various re-

volts that culminated in Colombian independence in 1819. Two years after that date, however, the people of Panama proclaimed their independence and became part of the old republic of Colombia. This was a strongly centralized government held together by little but Bolívar's personal influence and power. It was shattered in 1831, the year after his death, and three new republics were formed, namely, Venezuela, Ecuador and New Granada. The last named included the Isthmus. Strangely enough the form of government of the new republic was practically identical with that which had brought it to revolt against Colombia, and equally ill-adapted to its heterogeneous elements. Moreover, there was no simple and speedy means of intercommunication such as might have welded the country into some national unity. In the existence of this type of government is the philosophic key to the history of both the old republic of Colombia down to 1831, and after that date of New Granada, the United States of Colombia, and the republic of Colombia (the present name of the country). It was in the very nature of things that as New Granada had broken from Colombia, so Panama, New Granada's remotest part, must break, or attempt to break from New Granada. A state's rights or Federalist party did rapidly rise throughout New Granada. In 1840 revolutions broke out in most of the provinces. An independent "State of the Isthmus," containing the provinces of Panama and Veraguas, was proclaimed in 1841, but the Centralists were successful, the revolution was suppressed, and the old régime was restored. The sentiment against this method of government steadily increased until in 1855 by an act of the Congress of New Granada at Bogotá the autonomous state of Panama was erected out of the Isthmian provinces. But the sincerity of this act may well be questioned and its aim was probably political and the purpose to crush the Federalist party for good and all. But the attempt of the national government to revoke its act, and, it seems, to provoke a revolution, and then in crushing that revolution to put a stop to all Federal agitation, over-reached itself. The revolution in behalf of the new constitution was completely successful. For a score of years and more Panama, like the other states in the Colombian Union, enjoyed (more or less interruptedly) its individual rights. A Centralist uprising in 1885, however, effected a return to old conditions. The former state of Panama was again ruled from Bogotá, and became a department called Panama. This department was divided into four provinces, Chiriquí, Veraguas, Azuero and Panama; the last named province occupied the eastern half, approximately, of the department of the same name, with which it is very easily confused.

During this revolution in 1885 the United States landed marines to protect the transit of the Isthmus between the cities of Colón and Panama, a circumstance of material assistance to the Centralist insurgents, but an act undertaken simply for the sake of inter-oceanic and trans-Isthmian commerce. That it could have been for any reason other than this is impossible, since the right and duty of the United States to preserve neutrality in the Isthmian strip was due to a treaty made in 1846 with the government of New Granada, a government not

in existence in 1885. In short, the obligation was one to a territory and not to any power; and if to any power simply to that in control of the Isthmus, no matter what its relation to the original treaty-making power.

After 1885 the relations of Panama with Colombia were no closer nor more familiar than before. Several revolts took place, and in July 1900 under the lead of Porras, later a leading candidate for the vice-presidency of the republic, a desperate but unsuccessful attempt was made by a Liberal army to get control of the city of Panama. In 1903 a more successful plot was planned, growing out of the discontent of the people of Panama with the attitude of Colombia toward the Panama Canal Treaty with the United States. Whether through fear that the United States would in time gain sovereignty over the canal—there was an old saying that the canal when built would become the southern boundary of the United States—or a hope that the bid for the canal might be largely increased, the Colombian Congress refused to ratify this treaty and adjourned 31 Oct. 1903. By the terms of the Spooner bill this made the Panama Canal apparently an impossibility and the Nicaragua Canal a certainty, for the President had been bidden to treat for the Panama Canal, and if such negotiations failed, to carry through the project of the Nicaragua Canal. In short, the people of Panama would have been deprived of the fulfilment of their hopes of renewed commercial importance by this inexplicable action of the Colombian Congress, had not the revolution planned as early as the summer of 1903 offered a solution. How the desire for autonomy, the desire for a canal and the desire for the money to be paid for the canal, respectively, bulked in the minds of the revolutionary plotters it is difficult to say. The foregoing sketch of Panama's political history would show at least that a revolution for purely political reasons was a possibility. The mixture of motives amounts to little more than a coincidence of several impulses, each of which alone would have been sufficient. On 3 Nov. 1903—that is three days after the adjournment of the Colombian Congress—the municipal council of the city of Panama proclaimed the independent republic of Panama. There was no bloodshed. An army of 400 Colombians (mostly boys between 12 and 14) arrived 4 November in Colón, whence its general with his staff went to Panama; and upon his refusal to acknowledge the new republic, of which he knew nothing until the evening of the 4th, was imprisoned for a few days, but on the 7th with his army was shipped back to Cartagena from Colón. In the meantime upon 6 November the United States recognized the new republic, being satisfied that there was not the slightest internal opposition to its establishment. France's recognition followed 10 November, and soon afterward like action was taken by Germany, England and Russia. The remarkable haste with which the provisional government was recognized by that of the United States is not without precedent; in a Senate debate 5 Jan. 1904 Senator Lodge pointed out that in 1848 the French republic was recognized after three days and that the republic of Brazil had received formal recognition within two days after its formation. It is to be noticed also that Pan-

ama's government may justly be reckoned a "resumption" of previous independence. As to the action of our government in landing marines to protect the Trans-Isthmian Railroad its defense lies in an appeal to the Treaty of 1846, to the precedent of 1885, when the Centralist cause was as much (and as unintentionally) aided as it was checked in 1903, and to the principle that it is the Isthmian commerce that we aim to protect by keeping the strip neutral rather than any government, and hence that an appeal from any established power in the Isthmus for protection of the railroad must be met by speedy and unhesitating action. The objections to this view of the case and the disagreement with the actions of the existing administration came from various sources: first, as in the case of the New Haven petition sent to the Senate 11 Jan. 1904, from unpartisan constitutional experts; and second from the opposition in Congress and the supporters of the Nicaragua route, who saw their last chance to win. The New Haven petitioners simply asked the Senate to make a careful and deliberate investigation. The opposition in Congress (and in the press) urged that the revolution in Panama was fostered if not actually started by the Republican administration (Roosevelt's) and the landing of troops was for the purpose of preventing Colombia from subjugating the rebellious department; in fine, that both revolution and recognition grew out of pure self-interest in the proposed canal. Whatever the merits of these arguments, the inability of the Democratic caucus to bind its members to oppose the Canal Treaty, the instructions from the Mississippi legislature to the senators from that State, and 11 Jan. 1904 the practical confirmation of the nomination of W. I. Buchanan to be Minister to Panama by the tabling of Senator Morgan's motion to reconsider, seemed to show that the actual opposition was political and temporary.

The provisional government founded 3 November was in the hands of a junta consisting of J. A. Arango, Tomas Arias and Federico Boyd. The last-named member of the junta arrived in the United States on 18 December and late the same day a Canal Treaty was signed by Secretary of State John Hay and the Minister from Panama to the United States, Philippe Bunau-Varilla, who had been formally received at Washington eight days before. This treaty closely resembles the convention made with Colombia; the compensation is the same; but the canal strip is made wider and the powers granted to the United States are larger. The junta named above took control of the government, being assisted by the following provisional cabinet: Minister of Government, Eusebio Morales; Minister of Finance, Dr. Manuel Amador Guerrero (later elected President); Minister of Foreign Affairs, F. V. de la Esprilla; Minister of Justice, Carlos Mendoza; Minister of Public Instruction, N. Victoria; and Minister of War and Marine, M. de Obarrio, Jr. On 27 December a general election of delegates to a national convention took place. In most instances municipal authorities acted as electors, the scheme of manhood suffrage originally promulgated having proved impracticable. Four delegates were chosen from each province except Panama, which elected eight, making a total of 32,

These delegates, meeting 15 Jan. 1904, were called to frame a constitution and to elect a President. The provisional government ratified the Canal Treaty 2 Dec. 1903, and five days afterward the treaty was submitted to the United States Senate for ratification by that body. On 16 Feb. 1904 Guerrero was elected President, with Arosemena, Obaldia and Mendoza as *designados*, or vice-presidents.

Article 2 of the treaty between the United States and the Republic of Panama, which was ratified by the United States Senate 23 Feb. 1904, and went into effect 26 Feb. 1904, provided for the cession, in perpetuity by Panama, of a strip of territory adjacent to the canal, as follows:

"The Republic of Panama grants to the United States in perpetuity the use, occupation and control of the zone of land and land under water for the construction, maintenance, operation, sanitation and protection of said canal of the width of 10 miles, extending to the distance of five miles on each side of the centre line of the route of the canal to be constructed; the said zone beginning in the Caribbean Sea, three marine miles from mean low-water mark, and extending to and across the Isthmus of Panama into the Pacific Ocean to a distance of three marine miles from mean low-water mark, with the proviso that the cities of Panama and Colon and the harbors adjacent to said cities, which are included within the boundaries of the zone above described, shall not be included within this grant. The Republic of Panama further grants to the United States in perpetuity the use, occupation and control of any other lands and waters outside of the zone above described which may be necessary and convenient for the construction, maintenance, operation, sanitation and protection of the said canal or of any auxiliary canals or other work necessary and convenient for the construction, maintenance, operation, sanitation and protection of the said enterprise. The Republic of Panama further grants to the United States in perpetuity the use, occupation and control of all islands within the limits of the zone above described, and in addition thereto the group of small islands in the Bay of Panama named Perico, Nacs, Culebra and Flamingo."

In compensation the United States paid \$10,000,000 for the concessions and agreed to pay \$250,000 annually, beginning in the 10th year after the ratification of the treaty. The uneasy conditions prevailing throughout the Central American countries during 1907 and the early part of 1908 were particularly manifest in Panama, especially as the time for the election of a new President drew near. This uneasiness caused some apprehension at Washington lest the Canal Zone might become affected in some way. Charges had been made by one of the political parties that frauds had been perpetrated in the previous elections and that the members of the opposition party had not been allowed to register. A request was, therefore, sent in May 1908 to the United States to appoint a commission to assure a fair election. In order to pacify all the political elements Secretary of War Taft was sent to Panama. Ricardo Arias, Secretary of Foreign Relations, was the candidate of the Government party for the presidency and José Obaldia was the candidate of the

Liberal party in opposition to the government. The latter, while popular with the people, was not so with the government and apprehension was expressed lest the former should use the power of the government and police forces to hold a dummy election and declare himself elected. Upon his arrival Taft decided to appoint American representatives to observe the elections which were to be held on 12 July, and made it plain to the political parties that if frauds were permitted that might lead to disorder, riot or insurrection the United States would preserve order according to the terms of the treaty. A commission of electoral inquiry was appointed by Panama to investigate and a list of the actual voters in each polling precinct was made. Thereupon Arias withdrew from the contest and Obaldia was elected almost without opposition.

Government.—By the provisions of the constitution adopted 13 Feb. 1904, the country has a centralized republican form of government. The executive authority is vested in a President elected for a term of four years by popular vote; the President is assisted by a cabinet of five members. The legislative branch of the government consists of a single body of deputies called the National Assembly and the members are elected for four years. The sessions of this Assembly are held at the city of Panamá once every two years, and extraordinary sessions may also be called by the President of the republic. The judicial branch comprises a Supreme Court of five judges, appointed by the President for a term of four years; a Superior Court and several Circuit Courts (appointments to both made by the Supreme Court for four years); and Municipal Courts, whose judges are appointed by those of the Circuit Courts for one-year terms. For local government the republic is divided into eight provinces, each of which in turn is divided into municipal districts. The affairs of the provinces are administered by governors, appointed by the President of the republic for one-year terms, and those of the municipal districts by mayors and municipal councils, the latter elected by direct vote for two years, the former (the mayors or "*alcaldes*") appointed for one year by the provincial governors.

Education.—The Department of Public Instruction has charge of all elementary, secondary and special schools and establishments of learning, both public and private; of the Pedagogical Library and of the National Museum. The system of public education includes the kindergarten, for children five and six years of age, and primary schools for children of the ages seven to 14; these primary schools being organized in six grades, for which official courses of study are provided; and the instruction must be under official supervision even when given in private schools or at home. An obligatory course of only three years is established in rural schools. Among the special institutions above referred to are the School of Arts and Crafts, the National School of Music, the College of Commerce and Languages, the National Institute and a recently established school for the instruction of native Indians. (Consult 'Report of Commissioner of Education,' Washington 1915, and Pan-American Union handbook 'Panama,' Washington 1916). In 1917 the National

Assembly authorized the executive to found and maintain a Pan-American University in Panama City. The university is to give preference to courses in Spanish and English literature, tropical medicine and law. The National Institute of Panama is to serve as a base for the new university. Altogether the government maintains 398 public schools throughout the provinces. There are about 375 teachers in these schools and about 22,000 pupils (excluding 1,720 children enrolled in the schools of the Canal Zone). There are also about 12 private institutions and about 60 young men and women are being educated in the United States and elsewhere at the cost of the Panama government.

Industry and Commerce.—The cultivation of bananas on a large scale and of cacao, sugarcane, tobacco, rice, maize, etc., on a small scale, should be mentioned. Agriculture is practically undeveloped because of poor transportation facilities. The sugar industry is important in Los Santos and Veraguas, but could be greatly extended. The coconuts and pineapples of this region deserve their good report. Stock-raising is also an important branch (estimated number of cattle about 200,000; horses, 15,000; mules, 2,000; pigs, 30,000; and goats, 5,000). Mining is carried on in the Darien district and Veraguas Province; pearls are obtained at the Pearl Islands, Panama Bay, and coral and sponges are found near the coasts. Forest products are both valuable and interesting. Manufactures are few and unimportant. Chocolate, mineral waters, ice and soap are made for local consumption. The government maintains a monopoly in the production of tobacco, cigars, cigarettes and salt, and lets these to individuals. A law fixing the responsibility of employers for accidents to workmen was passed by the Congress of Panama on 6 Nov. 1916, and was promulgated in the *Gaceta Oficial* 10 days later. One of the features of the law is that if insurance companies are established in the country, employers may insure their employees for the amounts which would be due them in case of injury by accident while at work. The part of the law that provides for indemnity to victims of accident became effective 16 May 1917, while the remainder of the law went into effect on 16 Feb. 1917.

Chief exports are bananas, coconuts, cocobola wood, ivory, nuts, medlar juice, mother-of-pearl, hides, tortoise shell, rubber (from trees scattered in the forests), skins, ipecac, sarsaparilla, brown sugar, cacao and balata. Chief imports are rice, cigarettes and cigars, sugar, lard, coffee, kidney beans, eggs, candles, chocolate, Indian corn (maize), cheese, beer, food pastes, petroleum, gasoline, leather, butter, leaf-tobacco, etc. In the last normal year before the European War (1913) imports from the United States were valued at \$6,378,702.29; from Great Britain, \$2,465,431.54; from Germany, \$1,078,167.72; from France, \$336,816.38; from China and Japan, \$266,772.62; from Spanish America, \$238,684.48; from Belgium, \$208,539.98; from Italy, \$168,881.59; from Spain, \$162,574.09. The total foreign trade in that year was \$16,780,027.59 (imports valued at \$11,397,000.05 and exports \$5,383,027.54). In 1914 the total imports were valued at \$9,885,475 and the exports at \$5,163,000. Of the total imports \$6,396,275 came from the United States (exclusive of canal ma-

terials), \$1,835,890 from Great Britain, \$460,455 from Germany, \$211,725 from France, \$109,090 from Italy and \$300,835 from Belgium. In 1916-17, 38,000 quintals of sugar were produced. Imports in 1921 totaled \$11,846,220 and exports amounted to \$2,599,380. Of the imports 75.2 per cent came from the United States (exclusive of canal materials), the remainder being divided between Great Britain, France, and Italy. In the same year (1921) the chief exports were bananas, coconuts, balata, cocoa, hides, tallow and gum. Principal imports are cotton goods, flour, iron, steel and their manufactures.

Banking and Finance.—The monetary system is based on the gold standard, its unit being the *balboa*, divided into 100 centesimos and representing 1.672 grammes of gold .900-fine, or 1.5046 grammes of pure gold, equivalent to \$1 currency of the United States. In actual circulation are silver half balboas, locally called pesos, and fractional silver and nickel coins, together with currency of the United States on a par basis. The revenues of the republic declined 30 per cent after July 1914, the causes being (as stated in 'Proceedings of the First Pan-American Financial Conference' Washington 1915) the diminution of imports due to the European War and the establishment (by the government of the Canal Zone) of commissaries privileged to import merchandise without payment of duties. On 26 Oct. 1915 an extraordinary session of the National Assembly was held to consider pressing financial problems. A contract with New York financiers (1915) provided for the establishment of the Bank of Panama, one-fourth of the directors to be named by the government of Panama. That bank, acting as fiscal agent and depository of the Republic of Panama, has power to issue legal tender notes up to the value of its capital. The revenue for 1916 was \$5,311,000 and the expenditure \$5,823,000. The revenue for the biennial period—1 Jan. 1921 to 31 Dec. 1922—was \$5,520,830 and expenditures, \$7,494,700. The republic has \$6,000,000 invested in the United States and \$2,000,000 capital in the Bank of Panama. A loan of \$3,000,000 was negotiated in New York in 1915 for the construction of the Chiriqui Railway.

Transportation.—Steamships from the United States and Europe, from South America and the West Indies, enter the port of Colón on the north coast; on the south coast, Balboa, the Canal Zone's Pacific port, is visited regularly by steamers from both north and south. A railroad three miles long connects Balboa with Panama City, from which the main line of the Panama Railroad extends to Colón, 48 miles. Other railway systems are those of the Bocas del Toro region, 151 miles of narrow-gauge track designed chiefly for the service of the banana industry and of the Pedregal, David and Boquete south-coast districts. The latter, when completed, will be about 52 miles in length. In 1917 a concession was granted for the construction of a railway on the Atlantic Coast from the mouth of the Chagres southwest to Almirante, about 31 miles. The Chirique line is about 80 miles in length. The great difficulty experienced in constructing and maintaining good roads on land through the tropical jungles directs attention to the possibility of improving and uti-

lizing the rivers for transportation. At present, the Tuyra River is navigable for many miles by small craft, and the same may be said of a number of other streams; but it is also true that floods during the rainy season (see *Climate*) prohibit continuous use. The government is planning extensive improvements in various parts of the country to facilitate communication and internal development. Provision was made in the 1917 budget for the construction of new roads and the repair of old ones, for the building of bridges, wharves and warehouses, etc. On 26 Sept. 1916 the new port of Mandinga, about 80 miles from Colón, was opened. An appropriation of \$200,000 is made for roads from Penonome to Puerto Posado and from Ancton to Penonome, another from the latter place to Cahecera and to Rio Chico.

Police, Post and Telegraph Offices.—No army is maintained, its place being taken by a national police corps of 1,000 officers and men. There are 96 post offices, handling about 2,500,000 pieces of mail-matter annually; 37 telegraph offices and two wireless-telegraph stations. The government in December 1916 appropriated \$25,000 for the installation and maintenance of a telephone line in the province of Colón, along the Atlantic Coast, starting from the city of Colón and terminating in Santa Isabel. Construction was begun 1 Mar. 1917. A concession for the establishment and maintenance of electric plants and telephone systems throughout the republic was granted by the government of Panama in March 1917. It was provided that the American concessionaire, when employing labor in accordance with the terms of that concession, must give preference to natives of Panama and must retain them in the proportion of at least 50 per cent. There are telegraph cables from Panama to North American and South American ports and from Colón to the United States and Europe.

MARRION WILCOX.

PANAMA, capital of the Republic of Panama, situated on a coral peninsula running into the Gulf of Panama. It has no actual port, but vessels anchor safely between the mainland and a chain of islands. Founded near the Pacific Coast in 1519 by Pedrarias Dávila, Panama became wealthy in the days of the Peruvian mines, and was the oldest and richest colony in America in 1671 when it was taken, looted and burned by the buccaneer, Sir Henry Morgan (q.v.). The present city, six miles from the site of the old, was built two years after, and with its granite

fortifications was long the strongest Spanish fortress on the Pacific. The rush of gold-hunters to California in 1849 renewed its prosperity somewhat and in 1855 procured for it railroad connections with Colón, a new port on the Atlantic. Beside mere reshipping business it has the large part of the export trade of what is now the republic (and was the department) of Panama. The government buildings is one of the city's most creditable new structures in point of architecture, and has been designed rather ingeniously to serve a variety of purposes, the east and west wings being given over to the offices of the executive departments, while in the south wing are the National Assembly rooms and in the north the National Theatre. The buildings of the National Exposition of Panama, which threw open its doors hospitably in 1916, are also noteworthy. Striking contrasts of past and present, the ancient and the extremely modern, are offered by such buildings as Santo Domingo church or the moderately old cathedral, on the one hand, and on the other every token of modernity—the tramways, automobiles, electric lights, modern shops, etc. Panama is the social and commercial, as well as the political centre of the country; in it the revolution against Colombia was carried out 3 Nov. 1903. Pop. 37,600.

PANAMA, Isthmus of, the tongue of land connecting the central and southern American continents and varying in width from 31 to a little more than 110 miles, the former measurement being taken from the Gulf of San Blas and the latter including Azuero Peninsula. The Isthmus runs east and west with a double curve in either coast line, so that the western hollow made by Mosquito Bay on the north side and the eastern indentation of the Gulf of Panama on the south side, each with a corresponding bulge opposite, give the entire Isthmus the shape of a recumbent S or of the sign of variation. In this more extended use of the term the words Isthmus of Panama are applied to the entire Republic of Panama (q.v.), that is, what was formerly the isthmian segment of Colombia (q.v.). The term is also used to designate the eastern and narrower part, corresponding roughly with the Miocene causeway between the northern and the Neotropical regions (see the article on LATIN AMERICA—section *Fauna and Flora*), to which the name of Darien was originally applied. The isthmus was reached by Columbus in 1502, and was crossed in 1513 by Balboa, who "from a peak in Darien" discovered the Pacific. The cities of Panama and Nata were colonized before 1520. The Isthmus was also the scene of the Darien scheme of colonization fathered by William Paterson. In spite of its having been known so long to European explorers, large parts of the Isthmus remained as a virgin field for ethnologists, geographers and naturalists long after the first Canal Commission from the United States undertook the great constructive work. The geologist of the Isthmian Canal Commission contributed to the *Scientific American*, 18 Oct. 1913, pp. 303–305, a study of the geological conditions on the Isthmus, giving prominence to the fact that there are, within the Republic of Panama, high mountain groups, but few, if any, mountain ranges, properly so called. "The older geographies," he writes, "informed us that

the North and South American Cordilleras were practically one continuous chain from Alaska to Cape Horn. This is quite incorrect, for the mountains of Panama . . . are units quite distinct geographically from the greater northern and southern continental ranges. Furthermore, they have had a different origin, for they are not due to folding by lateral pressure, but originated from intrusions of volcanic rocks, as necks, cores, masses and irregular dikes." These intrusive rocks are of five types: basalts, diorites, andesites, granodiorites and rhyolites. They were extruded in a molten condition through volcanic agglomerates, breccias and tuffs: through sandstones, limestones, argillites and shale beds, mostly of Oligocene age. A fact that any serious student will notice is that the bedded rocks cut by these bodies of igneous or volcanic rock are not well consolidated, except in the vicinity of the higher mountains where they have undergone such induration as the heat of the great masses of ejected lava occasioned. The basalt, the esite and rhyolite extrusions are principally post-Oligocene, "and seem to be largely Miocene in age." The diorite is, at least in part, pre-Oligocene, probably of Eocene time. The fact that the earthquakes are co-extensive with these mountain groups is evidence that the latter have been pushed up beyond the supporting power of their foundations and are even now settling back to adjustment. This consideration has an obvious bearing upon the problem of the "slides" in Culebra Cut. (See PANAMA CANAL). Both Gold Hill and Contractors' Hill are examples of such settled-down masses. Within the Canal Zone there are only two peaks that attain approximately 1,000 feet in altitude; and no summits within 30 miles of the Canal Zone are higher than 2,000 feet. In fact, this marked depression is so extensive that no mountains above 4,000 feet in height are found within 100 miles of the canal's terminal ports. In the western regions, however, and in those districts long the subjects of contention on account of the conflicting claims of the Republic of Panama (as inheritor of Colombia's contentions) and Costa Rica; we find high mountains, attaining 11,000 feet in two instances, and unquestioned evidences of much more recent plutonic activity. (For climate, fauna and flora, hydrography, ethnology, etc., see PANAMA; PANAMA CANAL).

PANAMA CANAL, a waterway connecting the Atlantic and Pacific oceans, cut through the Isthmus connecting the continents of North and South America. Its opening has solved the problem of international commerce which first intruded itself on the Western World in 1453 when Constantinople fell to the Turks and the great land routes to India and the Orient were closed to Christian Europe. Within half a century of the event Columbus set forth on his memorable voyage in search of a route to the East. When he reached the West Indies the natives told him of a strait through which it was possible to travel westward to the great sea over which lay an unhampered road to India.

Balboa also heard the legend of a water route to the west and explored the Isthmus of Panama in an endeavor to locate it. After his time the discovery of this mysterious stream furnished the chief incentive to most of the

exploration up and down the coast. While the strait remained undiscovered, the search for it gave birth to the idea of digging a waterway which would connect the two oceans. To Hernando Cortez, conqueror of Mexico, belongs the honor of first proposing the construction of this water route. His plans were cut short by the treachery of his followers, but he encouraged his cousin, Alvaro de Saavedra Ceron, to continue the project, and the latter finally elaborated plans for four routes—Daríen, Nicaragua, Tehuantepec and Panama—the identical routes which received so much attention in the 19th century. With the abdication of Charles V, who was favorable to the project, all interest in it was abandoned by his successor, Philip II. Interest in an inter-oceanic route was revived from time to time, however, and especially after the peoples of the Isthmus severed their political connection with Spain about 1823. Henry Clay was fully alive to the importance of the canal project, the completion of which (speaking in 1825), he said, "will form a great epoch in the commercial affairs of the whole world." In 1826 Aaron H. Palmer of New York entered into a contract with the Republic of Central America to construct a canal capable of accommodating the largest vessels afloat. Failing to enlist the financial aid then deemed necessary (\$5,000,000), Palmer's contract came to nought. President Jackson sent Charles Biddle to Nicaragua and Panama to examine the different routes, but the mission was nullified by the subsequent action of the President and Senate.

After the Mexican War, which planted the Stars and Stripes on the Pacific Coast, the commercial necessity for a transisthmian canal was recognized. Various plans were made and with each decade the need for the canal became more imperative. Several times a canal under American control seemed assured, but some difficulty of a political nature always arose. While discussion concerning a canal was rife, enterprising Americans had in 1855 linked up the Pacific and Atlantic coasts of the Isthmus of Panama by means of the Panama Railroad, which for a time relieved the congestion of transcontinental communication. The Civil War precluded for several years the construction of a canal, and before America was again ready to consider the project seriously the French had undertaken to engineer and finance the construction of a canal.

In 1876 Count Ferdinand de Lesseps became head of a committee which proposed to study the Isthmian Canal project. Its first meeting was held in May 1879, and was attended by 135 delegates, of whom 11 were from the United States. The "International Congress" decided that the Panama route was the most feasible, the most practicable route, having the Bay of Panama and the Gulf of Limon as terminals of a sea-level canal, which it was estimated would cost \$240,000,000. Meanwhile in 1878, Lucien N. B. Wyse and associates had secured a concession from the Colombian government granting the exclusive privilege of constructing and operating a transisthmian canal for a period of 99 years.

The French Company.—As a result of the deliberations of the International Congress a company was organized on 17 Aug. 1879 under

the title *Compagnie Universelle du Canal Inter-oceanique de Panama*, with Count de Lesseps as president. The Wyse concession was purchased for 10,000,000 francs (\$2,000,000) and the company set about making exact detailed surveys. The company was capitalized at \$80,000,000, in shares of \$100 each, which were opened to public subscription. The plan adopted by de Lesseps was for a sea-level canal 30 feet in depth, 72 feet bottom width and an estimated length of 47.2 miles, involving the excavation of 160,000,000 cubic yards of rock and earth, at a cost now placed at \$168,000,000 within a period of nine years. Beginning in February 1883 actual excavation was entered upon and within a short time there began to arise those serious obstacles which had been foreseen by the trained engineers who had voted against de Lessep's project at the conference. It was found that the estimates were far too low. By the middle of 1885 scarcely one-tenth of the estimated minimum excavation had been effected, and it was evident to all that the program originally outlined could not be carried out. Severe criticism and passionate discussion of the enterprise took place in France and the credit of the company being seriously impaired it was deemed necessary to resort to irregular and corrupt practices. Many members of the French legislature were corrupted. De Lesseps relinquished the directorship in 1887 and returned to France to be tried and disgraced in the courts of his native land. In the same year the lock-type of canal was adopted, but it was now too late to save the enterprise, and in 1889 the Civil Court of the Seine appointed a judicial receiver. The company was declared to be bankrupt, and examination showed that 80,000,000 cubic yards of earth and rock had been excavated at a cost of \$265,938,600; of this sum only \$156,654,687 was actually expended at Panama. The company was dissolved by the court and a liquidator appointed to take charge of the property and to carry out the enterprise if possible and with power to cede any or all of the assets to a new company. Extensions of time were secured from the government of Colombia. The New Panama Canal Company was organized in 1894 with a capital stock of 65,000,000 francs or 650,000 shares of 100 francs (\$20) each. Fifty thousand shares were given Colombia for a further extension of time, leaving about \$11,700,000 as working capital. The assets and property of the old company were transferred to the new by the liquidator and a commission of 14 engineers was appointed to investigate the project. Their report was favorable and excavation went on slowly, the new company expending about \$9,000,000 and excavating 5,500,000 cubic yards by the close of 1899. Meanwhile, public sentiment in the United States had become strongly impressed with the desirability of a transisthmian canal under American control. The Nicaragua route was generally favored by members of Congress and others, a fact which caused extreme anxiety to those interested in the New Panama Canal Company. The directors of the latter decided to bring the comparative merits of both the Nicaragua and Panama routes before the American government. The full report of the technical committee of the latter company was laid before President McKinley in December 1898. In March of the following

year the President was authorized to make an exhaustive investigation as to the most practicable and feasible route for a transisthmian canal that should be under the complete control of the United States and the absolute property of the latter. The President thereupon appointed the first "Isthmian Canal Commission" which was composed of the following members: Rear-Admiral John C. Walker, U. S. N.; Hon. Samuel Pasco; George S. Morison; Lieut.-Col. Oswald H. Ernst, U. S. A.; Lewis M. Haupt, C.E.; Alfred Noble, C.E.; Col. P. C. Hains, U. S. A.; Wm. H. Burr, C.E.; Prof. Emory R. Johnson. The commission examined the project of the New Panama Canal Company both at Paris and at Panama, and thereafter tried to have the company state definitely the conditions and terms under which its property and rights might be transferred to the United States. The company was reluctant to state its terms explicitly and as a result the commission reported in favor of the Nicaragua route in November 1901. When this report became known in France, the New Panama Canal Company was at once reorganized with new executives and immediately offered its property and rights in the canal to the United States for \$40,000,000. This change of front on the part of the company, who saw their last chance of disposing of their property slipping away, caused the commission to make a supplementary report, in which it advocated the Panama route as the most feasible in view of the altered conditions.

A long and somewhat acrimonious discussion of the relative merits of the Nicaragua and Panama routes ensued in Congress and not until June 1902 did legislation (Spooner Bill) pass authorizing President Roosevelt to acquire the rights and property of the New Panama Canal Company for a sum not to exceed \$40,000,000 and to secure by treaty with Colombia the perpetual control of the territory needed for operating the canal; the law also provided for the prosecution of the work by an Isthmian Canal Commission consisting of seven members to be appointed by the President.

The American Enterprise.—After the enactment of the Spooner law, the provisions of which are outlined above, negotiations were entered upon with Colombia for a concession. If unable to secure a satisfactory title to the property of the New Panama Canal Company, or "to obtain by treaty control of the necessary territory from Colombia," the President was empowered to negotiate with Costa Rica and Nicaragua for a concession, and having secured the privileges desired, to construct the canal by the Nicaragua route. The purchase price to be paid the New Panama Company was not to exceed \$40,000,000, including the Panama Railroad, and before paying over the money to the company the President was required to assure himself of the validity of the title to the property to be transferred and to await the exchange of ratifications of a satisfactory treaty with Colombia. The Attorney-General of the United States was promptly instructed to make the investigation concerning the validity of the title held by the New Panama Company, and his elaborate opinion, together with the data upon which his opinion was based, was laid before the President on 25 Oct. 1902. The Isthmian Canal Commission had previously investigated

the title and nature of the concessions involved, as had also the Senate Committee on Inter-oceanic Canals. The commission's report contains a full historical and analytical discussion of the subject of concessions. The relations of the original Panama Canal Company to the New Panama Canal Company were set forth, and the opinion expressed that the New Panama Canal Company was able to sell its concession and property to the United States, provided the representative of the rights of the old company, the "liquidator," gave his approval of the sale, and united with the new company in the offer to sell. Shortly after this report was made the New Panama Canal Company offered to sell out to the United States, and the liquidator gave his consent to the sale.

Treaty with Colombia.—The treaty granting to the United States the concession and rights necessary for the construction, operation and control of the Panama Canal was signed by Secretary Hay and the Colombian *chargé d'affaires*, 22 Jan. 1903, and ratified without change by the United States Senate, 17 March following. It is a lengthy treaty, containing 28 articles, but is remarkable for the conciseness and directness with which each provision is stated. The Canal Commission did not consider it necessary for the United States to acquire sovereignty over the territory adjacent to the canal. The desirability for the United States of having the sole and undivided ownership and control of the canal when constructed was emphasized, and the recommendation was made that the compensation, to be paid by the United States should be definitely fixed either as a single payment, or as a predetermined annual payment, or as a combination of these two methods. The treaty authorized the New Panama Canal Company to sell out to the United States; exempted the Panama Railroad Company from its financial obligation to Colombia, and gave the United States a lease for a period of 100 years, renewable at the option of the United States, of a strip of land 10 kilometers wide across the Isthmus of Panama. The United States not only recognized the sovereignty of Colombia over this leased strip, but "disavows any intention to impair it in any way whatever, or to increase its territory at the expense of Colombia or of any of the sister republics in Central or South America." The United States secured the right to construct the canal and harbors, to establish free ports at the termini of the canal, to maintain hospitals and drainage and sanitary works along the line of the canal and its dependencies, and to install waterworks and a sewerage system in Colón and Panama, with the authority to "collect equitable water rates during 50 years." Colombia agreed not to cede or lease to any foreign power any territory in the Department of Panama, and the United States guaranteed that no country should be allowed to seize such territory. It was provided that the canal should be neutral in perpetuity, in conformity with the treaty of 18 Nov. 1901, between the United States and Great Britain; but the United States reserved the right to protect the canal.

The unexpected rejection of the treaty by Colombia in the summer of 1903 at once put a new phase on the question and the promoters of the Nicaragua route again advanced their project and once more discussion was rife in

regard to the relative merits of the two routes.

Treaty with Panama.—The successful revolt of Panama from Colombia in November 1903, as fully described under PANAMA (q.v.), and the immediate recognition of the new republic by the United States and other governments, however, confined the canal question to the Panama route. The provisional government of Panama at once arranged a new treaty with the United States government for the construction and control of the canal, differing from the treaty with Colombia in that the Canal Zone was enlarged, and greater powers granted to the United States. This, known as the Hay-Varilla Treaty, was signed at Washington 18 Nov. 1903 and ratified in Panama 2 Dec. 1903. By its terms the United States guarantees and will maintain the independence of the Republic of Panama. Panama grants the use in perpetuity of a zone 10 miles wide, and its exclusive control for police, judicial and other purposes; cedes territory for subsidiary canals and the coast line within the zone; and if police and other matters in the cities of Panama and Colón prove unsatisfactory, the United States may intervene. The canal is to be neutral and open to the world's commerce. For these grants the United States agreed to pay \$10,000,000 on the ratification of the treaty and \$250,000 yearly beginning after 10 years. The sovereignty of Panama over all her territory to be recognized.

Plan and Organization.—On 4 May 1904 the United States took possession of the canal site and property. Major-General Whitfield Davis was appointed head of the Canal Commission with gubernatorial powers within the zone, his assistants being William Barclay Parsons, New York, William H. Burr, New York, Benjamin M. Harrod, Louisiana, Carl E. Crinsky, California, and Frank J. Hecker, Michigan. The preparatory work was begun on the plan of high-level locks, as favored by Congress in 1902. The average summit-level proposed was to be 85 feet above mean tide. This was to be secured by a dam at Bohío, the most important structure of the high-level canal. The dam proposed by the French Panama company was to be of clay founded upon a variety of material—hard clay, soft clay, sand, gravel, etc. The Isthmian Canal Commission decided upon a core-wall-and-earth dam, the core-wall to be carried down everywhere to rock, the latter being reached in places at a depth of 128 feet below sea-level. On 19 Dec. 1904, however, the chief engineer of the Isthmian Canal Commission laid his report before the Congressional Committee of Commerce. He was in favor of a return to the original plan of a sea-level canal as the best and cheapest in the end. The cost was estimated at \$300,000,000 and the time of construction 20 years.

Early in 1905 the Engineering Committee (Messrs. Parsons, Burr and Davis) also issued a report recommending a sea-level canal, which they estimated could be completed in 10 or 12 years for \$230,500,000. As outlined by them the canal was to extend 49 miles from the 36-foot depth mark in Colón Harbor to the similar depth-mark in Panama Harbor, and with a bottom width of 150 feet, was to be 30 feet in depth. As regards the natural features

of the Isthmus, the first section from the Atlantic to Bas Obispo is 29 miles of low, marshy and unhealthful surface, thick with tropical vegetation; work here was facilitated by the considerable amount of excavation done by the French, and a stretch of completed waterway. The second and most difficult section of the canal was in the hill ground from Bas Obispo to Pedro Miguel, 7.91 miles, and known as the Culebra Cut. The route was so well chosen, however, that it afforded the lowest crossing in the ridge between the oceans. The third section from Pedro Miguel to the Pacific, nine miles, is similar to the Atlantic side, low, marshy and unhealthful. The greatest difficulties to be overcome were in keeping the floods of the Chagres under control and the cut through the rocky height of Culebra, the isthmian backbone and continental divide rising 300 feet above sea-level, nine miles from the Pacific.

In consequence of the recommendations a series of radical alterations were made in the United States canal program for 1905, but on 30 March, Secretary Taft sent to President Roosevelt a drastic statement concerning the whole scheme, which was acted upon with such promptitude, that an executive order was issued on 3 April, reorganizing the Canal Commission. Theodore P. Shonts was appointed chairman, Charles E. Magoon was appointed governor of the Canal Zone and also to serve as Minister to Panama; John F. Wallace, chief engineer; Rear-Admiral M. T. Endicott, U. S. N.; Brig.-Gen. Peter C. Hains, U. S. A.; Col. Oswald H. Ernst, Engineering Corps, U. S. A.; and B. M. Harrod. A comprehensive list of instructions concerning the duties of the new commissioners was issued. In June Mr Wallace was succeeded by Mr. J. F. Stevens as chief engineer. Among other recommendations of Secretary Taft was the formation of an advisory board to consider the best design of canal. A board of consulting engineers was appointed, which after several sittings divided on the plan of canal.

Sanitation.—Meanwhile preparatory work proceeded upon the canal cuttings but during the summer of 1905 the work of excavation was virtually suspended. The mortality had proved alarming and Governor Magoon diverted most of the labor to sanitary work. Attention was devoted to the draining and oiling of marshes for the destruction of mosquitoes propagating malaria and yellow fever, to the sewerage systems of the Isthmus, and to a good water supply for the cities of Panama and Colón with the result that the mortality from yellow fever was soon completely reduced. The housing, provisioning and entertainment of the laborers in the Zone were also arranged. Colonel William C. Gorgas of the Medical Department of the Army began the remarkable work of sanitation, without which it is doubtful if the canal could ever have been completed, certainly not without an appalling loss of human life. General Gorgas's interesting book, 'Sanitation in Panama,' contains the best account of the admirable achievements in this department. We have no means of telling (General Gorgas says, in effect) what was the sick rate of the French during the period of construction under the old French company, from 1881 to 1889, but we know that it was very

large. We can safely calculate that their constant sick rate was at least 333 per 1,000, or one-third their force. Now our force during the 10 years of construction averaged 39,000 men. If we had had a similar constant sick rate, we should have had 13,000 sick employees in our hospitals every day during the 10 years of construction. As it was, we had only 23 per 1,000 sick each day, a total of 900 for the whole force; that is, we had about 12,000 fewer men sick every day than had the French. This 12,000 men per day saved from sickness must be credited to the sanitary work done on the Isthmus. Now let us consider the totals: We had an average of 900 men sick every day. For the year, this would give us 328,500 days of sickness, and for the 10 years, 3,285,000 days of sickness. If our rate had been 300 per 1,000, a very moderate figure compared with what it was under the French, we should have had 11,700 sick every day. For the year this would have given us 4,270,500 days of sickness, and for the 10 years 42,705,000, a saving of 39,420,000 days of sickness during this period. This saving must be credited to sanitation. Again, it cost us about \$1 a day to care for a sick man on the Isthmus. The commission cared for the sick free of charge. Therefore every day of sickness prevented lessened the expense that the commission had to bear by \$1. It follows that the commission saved by the work of its sanitary department, if we consider the whole 10 years of construction, \$39,420,000.

This represents only one phase of the saving due to sanitation. We must further consider that, if 300 men out of every 1,000 had been sick every day, the efficiency of the other 700 would have been correspondingly decreased. The other 700 would have been more or less debilitated and more or less depressed, and the amount of work turned out daily by each man would have been considerably less than it actually was for the employees enjoying good health and cheerful surroundings. The commission would have had to pay considerably higher wages if the Isthmus had continued to bear the reputation it had always borne during the years preceding 1904; if, for instance, it had been known that three out of every 10 men going to work on the canal would be sick all the time, and that two out of every 10 would die each year, and that the whole 10 would be dead at the end of five years. Great loss was caused in the first years of the American assumption of the task by the demoralization among the working force, and almost stoppage of work, which took place during periods of exacerbation in the yellow fever period or when prominent employees died of that disease. Great loss also occurred to the French on this account. Those most familiar with the conditions state that a larger sum in dollars and cents was saved to the commission in these ways than was saved by the direct decrease in the number of sick. Considering all these factors an estimate was made that the sum of \$80,000,000 was saved to the United States by the sanitary work done on the Isthmus during the 10 years of construction. This is the purely commercial side of the question. Of much greater importance is the moral argument that can be adduced from the saving of

life and suffering that results from such measures. During the 10 years of construction, the commission lost by death only 17 out of every 1,000 of the employees. That is, from the whole force of 39,000 men, 663 died each year, and for the whole construction period the loss was 6,630 men. If the sanitary conditions had remained as they had been up to 1904, and the commission had lost, as did the French, 200 employees out of each 1,000 men on the work, that would have made the loss 7,800 men each year, and 78,000 during the whole construction period. It is evident, therefore, that 71,370 human lives were saved by the work of the sanitary department during the building of the canal.

The distinguished author refers to the sanitary work done in the Canal Zone as the first great demonstration that the white man can (or could, if such measures were generally adopted and applied) live as well in the tropics as in the temperate zones.

Lock-Canal Plan Adopted.—The report of the board of consulting engineers was submitted to the Senate Committee on Inter-oceanic Canals and extended deliberations took place upon the two problems of a high-level lock canal to cost \$147,000,000, and not over eight years to build, and a sea-level waterway to cost about \$250,000,000 and from 12 to 15 years to build. On 17 May 1906, the majority report of the Senate committee in favor of a sea-level type of canal was submitted by Senator Kittredge. Notwithstanding this report the idea of a lock canal prevailed in the end. On 15 June 1906, Congress in committee of the whole voted in favor of a high-level lock canal by a majority of 110 to 36, and on 21 June the Senate also declared for a lock canal. President Roosevelt signed the bill on 29 June 1906. Thus the long-discussed question was finally settled and work was at once more vigorously entered on. Under the direction of Chief Engineer Stevens commendable progress was made by the early part of 1907. Friction developed, however, between the members of the commission and the Washington authorities, and, in 1907, when it was proposed that the commission should remove from Washington to the zone and do its work on the field of operation instead of at a distance, Chairman Shonts and Chief Engineer Stevens resigned. President Roosevelt then radically reorganized the commission, under date of 1 April 1907. The earlier policy of taking men from civil life to superintend and execute the work was abandoned as a failure. The new commission was made up of government officials and was attached to the War Department under the immediate authority of the Secretary of War. The commission was constituted as follows: Lieut.-Col. George W. Goethals, corps of engineers, chairman; Major David DuB. Gaillard, corps of engineers; Major William L. Sibert, corps of engineers; Rear-Admiral H. H. Rousseau, civil engineer, U. S. N.; Hon. Joseph C. S. Blackburn, Colonel William C. Gorgas, medical department, U. S. A.; and Mr. Jackson Smith. Mr. Smith resigned in 1908, and Major H. F. Hodges was appointed to fill the vacancy. Senator Blackburn resigned in 1909, and was succeeded by Maurice H. Thatcher. The latter resigned in 1913 and was succeeded by Richard L. Metcalf, who served until April 1914, on which date—the canal be-

ing then essentially finished—the Isthmian Canal Commission was abolished, and attention given to the organization of an operating force. In the course of the work many details were altered and at the conclusion of the work the canal plan was as follows: sea-level approach channel in Limon Bay 4.5 miles long, 500 feet wide at bottom and 41 feet deep below mean sea-level; straight strip of sea-level canal for 5.5 miles to Mindi where there is a slight bend followed by a straight channel for 1.5 miles to the locks at Gatun, three in number with a combined lift of 87 feet to the summit level of Gatun Lake, favored by the construction of an earth dam of unusual dimensions extending across the valley at Gatun. The flow of the Chagres into the lake is discharged from the latter by a concrete spillway. The normal summit level of the lake is 85 feet, but provisions are made so that the water surface can be carried at any level between 80 and 87 feet, a matter of the greatest importance during the

Diagram of spillway, Gatun dam.

dry season. The locks at Gatun are close together and vessels pass directly from one lock into the next. All three locks are in duplicate, corresponding locks adjoining with only a dividing wall between, making it possible for a vessel to ascend one set, while another vessel descends the adjoining set of locks. Each lock has a usable length of 1,000 feet and a usable width of 110 feet. From the locks at Gatun there was no digging necessary for 17 miles except for an occasional hill-top or mound because of the great depth of the lake. The channel for 3.5 miles from the locks is perfectly straight, with a depth of 75 feet and is 1,000 feet wide. At this point there is a great bend

Diagram of the Gatun dam, spillway, and locks.

in the canal followed by a straight channel for 4.5 miles to near Bohio, where there is a slight bend. From Bohio to Buena Vista the canal is 1,000 feet wide, after which it again runs

with only two bends for five miles to Tabernilla. For three miles to near San Pablo the channel width is only 800 feet. The lake narrows past San Pablo and over the site of Gorgona. It retains a width of from 500 to 800 feet to Bas Obispo, where the great Gaillard (Culebra) Cut is entered. For 8.1 miles through the cut the bottom width is only 300 feet, with a minimum depth of 45 feet at normal lake level. The end of the high level is reached at the Pedro Miguel lock, also in duplicate, by which a descent (or ascent) of 30 feet is made to the 55-foot level of Miraflores Lake, 1.30 miles in length, with 500-foot channel and 45 feet in depth. There are two locks in duplicate at Miraflores, with a combined descent (or ascent) of 45 feet at Pacific high tide or 65 feet at low tide, by which tidewater is again reached. The

Cross-section of Gaillard (Culebra) cut, showing relative amount of excavation by the French and Americans.

canal runs 2.5 miles to Balboa, after which it becomes a deep water channel in Panama Bay for a distance of nearly five miles. To sum up, the length of the canal from deep water to deep water is 50 miles; length from shore line to shore line, 40 miles; bottom width of channel, maximum, 1,000 feet; bottom width of channel, minimum, in Gaillard Cut (otherwise known as Culebra Cut), 300 feet; locks in pairs, 12; locks, usable length 1,000 feet; locks, usable width, 110 feet; Gatun Lake, area, 164 square miles; Gatun Lake, channel depth, 45 to 85 feet; Gaillard Cut (Culebra Cut), channel

depth, 45 feet; excavation by the French, 78,146,960 cubic yards; excavation by the French useful to present canal, 29,908,000; estimated value to canal of excavation by the French, \$25,389,240; value of all French property there, \$42,799,826; work begun by the Americans, 4 May 1904: excavation accomplished to 31 March 1915 (when only about 6,000,000 or 7,000,000 cubic yards remained to be excavated in canal

proper), 232,440,945 cubic yards; concrete, total for canal, excluding terminals, 4,844,566 cubic yards; time of transit through completed canal, 10 to 12 hours; time of passage through locks, three hours; relocated Panama Railroad, length, 47.11 miles; Canal Zone, area, 436 square miles; canal and Panama Railroad forces actually at work in September 1913, about 37,000 (including about 5,000 Americans); payment to New Panama Canal Company (for the French property), \$40,000,000; payment to the Republic of Panama, \$10,000,000; estimated total cost of the canal, \$375,000,000 (estimate given by General Goethals).

Slides.—The engineers of the canal had to deal with peculiar conditions in the shape of huge masses of earth and rock which slid into the canal excavation both before and since completion. These slides made up 29,431,000 cubic yards of the total American excavation of 232,353,000 cubic yards or 12½ per cent and 30 per cent of the excavation at Culebra. Slides developed where the side slopes of the excavation were left too steep to provide a stable bank. The West Culebra slide involves 68 acres with about 11,000,000 cubic yards of excavation, the East Culebra an area of 55 acres and 8,000,000 cubic yards, and the Cucaracha slide 50 acres and 5,300,000 cubic yards. In September and October 1915 these slides suspended navigation on the canal.

The Canal in Operation.—On 7 Jan. 1914 the self-propelled steamer, the crane boat *Alex. La Valley*, made the first passage of the canal and on 15 Aug. 1914 commercial traffic was inaugurated. On the latter day the steamer *Ancon* made the passage in 9 hours and 40 minutes. The canal has since been in operation, except during the period September 1915–27 March 1916, when the slides interfered with navigation. In the two years ending 14 Aug. 1916, exactly two years from its inaugural opening, 2,097 vessels aggregating 7,046,407 tons passed through, with cargoes aggregating 9,031,613 long tons. In the fiscal year ending 30 June 1917 1,876 vessels made the passage of the canal. These had a net tonnage of 6,009,356 tons and carried 7,229,255 tons of cargo. The tolls collected from vessels passing through the canal from its opening to 1 Jan. 1917 aggregated \$9,461,717. In the same period the operating and maintenance charges amounted to \$14,717,072, leaving an operating deficit of \$5,255,355.

Tolls.—Panama Canal toll rates are the following: (1) On merchant vessels carrying passengers or cargo, \$1.20 per cent vessel ton (each 100 cubic feet) of actual earning capacity. (2) On vessels in ballast without passengers or cargo, 40 per cent less than for those of class 1. (3) On naval vessels, other than transports, colliers, hospital ships and supply ships, 50 cents per displacement ton. (4) On army and navy transports, colliers, hospital ships and supply ships, \$1.20 per net ton, the vessels to be measured by the rules that are also employed in determining the net tonnage of merchant vessels. In time of war, as at other times, the canal may be used by all navies, according to treaties now in force which provide that it "shall be free and open to the vessels of commerce and war of all nations and shall never be blockaded, nor shall any right of war be

exercised nor any act of hostility be committed within it."

The Canal in its Relation to International Commerce.—An interesting and valuable study of the effect of the canal upon international trade competition, by Mr. Hutchinson (see *Bibliography*), contains the following reference to this canal: "A vast region bordering the Pacific, with huge population and enormous resources, crying out for economic development, is being brought into a new relationship with the older economic sections of the world best able to aid them in the fulfilment of their desires." The author says truly that many Pacific countries need European and American capital, need immigrant population, need the stimulus and direction of American or European enterprise. Their latent resources cannot be developed fully in the absence of transportation facilities, railways, roads, harbor and street improvements, modern sanitation, public works of all sorts. Their industries need the introduction of modern equipment and methods. In brief, the Atlantic must supply the Pacific. With the opening of the Panama Canal, a new facility of intercourse has been created. Goods, tourists, agents, mails, emigrants, can now reach many of the Pacific countries more quickly and conveniently. New growth of economic, commercial, social and intellectual intercourse inevitably follows. The geographical position of the canal and the trend of development in the Pacific countries, as the writer points out, are such that the eastern portions of the United States are most favorably situated to play a part in this new growth. With reference to many Pacific regions the industrial eastern part of the United States has hitherto been at a disadvantage compared with Europe; but the handicap is either converted into an advantage by the canal, or greatly reduced. In those regions where the United States has already held some advantage, her position is greatly strengthened by the facilities offered by the new route.

PANAMA CONGRESS, a congress of representatives of various American nations held at Panama, June 1826, for the discussion of matters of interest to the American peoples. The

meeting was originally intended only for South and Central American delegates, but the ministers of Mexico, Colombia and Guatemala at Washington formally invited the United States to be represented. After some friction in congress two delegates were appointed, but at the congress 22 June 1826 the American delegates were not present, one having died en route and the other having been delayed in transit. Chile and Brazil approved of the congress but did not send delegates. Ten sessions were held.

PANAS, Photinos, French surgeon and ophthalmologist: b. in Cephalonia, one of the Ionian Islands, 30 Jan. 1832; d. 1903. After an elementary course in medicine at Corfu, he went to Paris, where in 1860 he was graduated from the School of Medicine. Three years later he became a naturalized citizen of France and was then appointed associate professor and surgeon to the Central Bureau. In 1864 he became ophthalmic surgeon to the Bicêtre hospital, in 1865 to the Midi and Lourcine hospitals, in 1868 to the Saint Louis and Saint Antoine hospitals, in 1872 to the Lariboisière hospital, and in 1877 to the Hôtel Dieu. In 1879 he was appointed professor of clinical ophthalmology in the Ecole de Médecine. Panas rendered valuable service in the Franco-Prussian War and achieved some renown through his introduction into France of Lister's methods and by his operations in ovariectomy. He was more widely known, however, for his writings in medical journal on subjects connected with his specialty, and for his works on ophthalmology, the most important of which are 'Leçons sur le strabisme,' etc. (Paris 1873-93); 'Leçons sur les kératites' (1876); 'Leçons sur les affections de l'appareil lacrymal' (1877); 'Leçons sur les rétinites' (1878); 'Anatomie pathologique de l'œil,' with Remy (1879); 'Sur le glaucome et les néoplasmes intraoculaires' (1893); 'Traité complet des maladies des yeux' (1894); 'Leçons de clinique ophtalmologique' (1899), etc.

PANATHENÆA, Greek festivals, celebrated at Athens in honor of Athena. The Panathenæa were distinguished into the greater and the less, in both of which three kinds of games were exhibited, conducted by 10 presidents. On the first day were races with torches in the Ceramicus; on the second, gymnastic exercises and imitations of naval fights; on the third, contests of music and declamation, and dramatic representations. An olive crown from the groves of Academus and a vessel full of sacred oil were the rewards of the victor. Then followed the sacrifices and the sacrificial feasts.

PANAY, pä-ni', Philippines, the most north-western island of the Visayan group, lying a little to the southeast of the centre of the archipelago, bounded on the east by Iloilo Strait, and on the west by Mindoro Sea; area 4,611 square miles. The largest of its dependent islands is Guimaras (243 square miles), lying to the southeast of Panay.

Topography.—The shape of the island is roughly triangular. A mountain range extends from the peninsula of Buruanga in the north-west to the extreme south and from Maymagui

Mountain, in the centre of this range, another mountain system extends to the east and north. The island is thus naturally divided into three provinces. There are three large rivers, the Panay, Jalaur and Aclán, and numerous smaller streams. The coast on the east and north is well indented with bays and harbors.

Industrial Resources.—The chief industry of Panay is agriculture; cotton, corn, chocolate, pepper, coffee, tobacco, sugar, rice and copra are raised; the last three are the staple crops, and of excellent quality. There are also large numbers of livestock raised, cattle, carabao and horses, excellent grazing lands being found in all parts of the island. The horses raised in the province of Iloilo are very highly prized throughout the archipelago. The forests are valuable; among the more important woods are molane, ebony and sibucan, large quantities of which are exported; honey, wax and pitch are also gathered in considerable quantities. The mineral resources have not been scientifically developed; gold is found and is mined in small quantities; and fine marbles and tonalite are quarried to some extent; there are deposits of gypsum, marl and iron; quicksilver and copper are also reported. The mechanical industries are well advanced and produce for export; fine fabrics of pineapple fibre, jusi, sinamay and cotton are manufactured; also sugar sacks, hats and palmleaf baskets; the woven fabrics of the province of Antique are especially well known, the looms giving employment to over 12,000 women; lime of good quality is manufactured in Iloilo. The fisheries are also valuable, particularly those of the island of Guimaras. Within the three provinces there are excellent road systems; but as the mountains are almost impassable the trade between provinces is entirely by sea; there is also a large foreign trade, the town of Iloilo (pop. 60,000) being next to Manila in commercial importance.

People and History.—The people of Panay are almost entirely of Visayan race; a few thousand wild Mundos and a few Negritos live in the mountains. This island was a stronghold of the Filipino insurrection; it was first occupied by United States troops in the early part of 1899 but the island was not completely pacified until January 1901. The island was divided into three provinces (in accordance with the natural divisions), Antique, Cápiz and Iloilo; the former Spanish commandancia of Concepcion was consolidated with Iloilo. Pop. of island, 743,646.

PANAY, Philippines, a pueblo of the province of Cápiz, island of Panay, situated a few miles inland from the northern coast, three miles southeast of Cápiz, the provincial capital. Pop. 15,500.

PANAY RIVER, a river of the province of Cápiz, island of Panay, rises on the eastern slopes of the Tapas Mountains, flows north and empties into the sea near the town of Cápiz; length, 38 miles. It is one of the most important rivers of the island of Panay, has five chief tributaries, and drains the greater portion of the province of Cápiz. It has a high-tide depth of 13 feet at its mouth and is navigable for large native craft for a considerable distance.

PANCHATANTRA, pān-cha-tān'tra, an old collection of apologues and stories in Sans-

krit. Vishnuserman is represented as the narrator of the stories and author of the book. The Panchatantra has been frequently revised. Wilson had three widely varying manuscripts before him while he drew up his analysis of the work. Kosegarten, who first edited the Sanskrit text, used 11 varying manuscripts. In these he recognized two versions, one simple, the other more extended and elaborated. Neither of these can be the first form of the work, which must have been a still more ancient text.

Some of the apologues contained in the Panchatantra occur in the Mahabharata, others originate in Buddhist books, and several abridgments or imitations occur elsewhere in the Sanskrit.

The 'Panchatantra' is one of the works styled in India as 'Nitiśāstras' (*śāstra*, "book of knowledge," and *niti*, "conduct"), written for the instruction of kings and all those called to take a share in the government. The five books of which it is made up form as many distinct sections related to each other by a preface in which a king, after taking the advice of his councillors, entrusts to a Brahman the training of his three sons. The Brahman composes the Panchatantra for the edification of the young princes and by the reading of that work he succeeds in overcoming their idleness and in developing their minds.

The first book has for its title 'Mitrabhedha' ('The Disunion of Friends'). It aims at acquainting kings with the danger incurred by lending ear to the insinuations of those who seek to sow divisions between a prince and his faithful subjects. The second book, 'Mitraprapti' ('The Acquisition of Friends'), shows how advantageous it is for men to unite and help each other. The third book, 'Kakolukiya' ('The War of the Crows and the Owls') demonstrates the danger of trusting to untried men or to enemies. The fourth, 'Labdhapranasana' ('The Loss of Acquired Good'), proves that we frequently lose by imprudence what we had acquired with difficulty. The fifth and last book, 'Aparikshitakaraka' ('Inconsiderate Conduct'), shows the danger of being precipitate. The narrative is interspersed with sentences, maxims, thoughts, extracts from legal codes, poems and dramas. Consult Frazer, 'Literary History of India' (1896); Kosegarten, 'Panchatantrum' (1848-59); Lancereau, 'Panchatantra,' French version (1871); Schmidt, 'Panchatantra, Textus Ornatus,' German version (1901).

PANCOAST, Henry Spackman, author and educator: b. Germantown, Pa., 24 Aug. 1858. He was educated at Germantown Academy and by private tutors. Studied law, admitted to the bar in 1882 but retired from practice in 1887 to devote himself to writing and teaching. Received degrees of L.H.D., Trinity, 1912; A.M., University of Pennsylvania, 1913. Author of 'Representative English Literature' (1892); 'Introduction to English Literature' (1895, 3d ed. 1907); 'Study Lists, Chronological Tables and Maps' (1908); 'Introduction to American Literature' (1898; revised ed. 1911); 'A First Book of English Literature' (with P. V. D. Shelly; 1911); 'Standard English Poems' (1900); 'Standard English Prose' (1902); 'Early English Poems' (with J. D.

Spaeth; 1911); 'A Vista of English Verse' (1911); 'English Prose and Verse' (1915). Also monographs on questions of Indian Rights and contributions to magazines.

PANCOAST, Joseph, American surgeon: b. Burlington, N. J., 1805; d. 7 March 1882. In 1828 he was graduated at the University of Pennsylvania and began teaching surgery in 1831. For a long period he was connected with various hospitals in Philadelphia; was professor of surgery in the Jefferson Medical College from 1838 to 1847 and professor of anatomy from 1847 to 1874. He resigned in the latter year, becoming professor emeritus, and was succeeded by his son, William H. Pancoast. He was a remarkably skilful operator, devised many improved methods, and made some important discoveries. Besides contributing to leading medical journals, he translated and edited various works, and published 'A Treatise on Operative Surgery' (1844; 3d ed., 1852) and 'A Treatise on the Structure, Functions and Diseases of the Human Sympathetic Nerve' (1831).

PANCOAST, William Henry, American surgeon: b. Philadelphia, 1835; d. 1897. In 1856 he was graduated at the Jefferson Medical College and subsequently studied in London, Paris and Vienna. He established his practice in Philadelphia and during the Civil War was superintendent of a hospital there. He joined the faculty of Jefferson Medical College in 1867 and in 1874 succeeded his father as professor of surgery there. In 1887 he was one of the founders of the Medico-Chirurgical College of Philadelphia, where he became professor of anatomy and clinical anatomy. Dr. Pancoast published a report in 1884 concerning the anatomy of the Siamese twins, which attracted wide attention.

PANCRAS, Saint, or PANCRATIUS ("Victor in every game") a christian martyr, who at the age of 14 defied the decree against Christianity issued by Diocletian and was accordingly put to death (304). He is regarded as the patron saint of children and there are many churches dedicated to him in England, Italy, France and Spain, and his festival is celebrated on the anniversary of his death (12 May).

PANCREAS, păn'krē-ăs. The pancreas *πανχρεας* (all flesh) is a large abdominal gland which has the double purpose of producing a digestive secretion which is poured into the upper part of the small intestine (duodenum), and of regulating the utilization of sugars and starches in the body. The latter function is carried on by an internal secretion which passes directly into the blood. The pancreas of the calf is used for food under the name of the "stomach sweetbread," in distinction to the "neck sweetbread," which is the thymus gland. In man the organ is irregularly prismatic in shape, is reddish-yellow in color, and lies with its long axis across the posterior wall of the abdomen behind the stomach at the level of the first and second lumbar vertebræ. It has been variously compared in shape to a hammer, to the letter "J" placed on its side, or to a dog's tongue. The right-hand end is the larger and is termed the head. A slightly narrower portion connects the head with the body of the gland which in turn terminates in an elongated

portion called the tail. The average dimensions of the gland are six to eight inches (15 to 20 centimeters) in length, one and a half inches (three and a half to four centimeters) in breadth, and one-half to one inch (one and a half to two centimeters) in thickness. In weight it averages two to three and a half ounces (60 to 100 grammes). The head of the organ lies just to the right of the vertebral column, and is encircled by the loop formed by the duodenum as it leaves the pyloric end of the stomach. The body extends to the left behind the stomach, and the tail usually touches the hilum of the spleen. Unlike the other abdominal organs the pancreas does not have a special artery from the aorta, but derives its blood supply through the branches from the celiac axis and the superior mesenteric artery. Its nerve supply comes through the branches of the celiac plexus, which are non-medullated, but provided with ganglia, and penetrate to the ultimate structural units of the organ, which they surround in fine networks. The gland pours its external secretion into the duodenum through a long duct (duct of Wirsung) running from left to right the length of the organ. It begins through the union of small ducts from the lobules in the tail and, increasing in size through the receipt of numerous tributaries, as it proceeds, finally reaches the head of the gland. On leaving the pancreas it joins the common bile duct, and together with this, passes obliquely through the wall of the second part of the duodenum three or four inches (8 or 10 centimeters) from the stomach, usually at the summit of a little elevation of the mucous membrane, called the papilla of Vater. It may, however, empty into the bile duct itself a short distance from the intestine. A second duct, the duct of Santorini, is usually subsidiary to the main duct and may empty into the duodenum by a separate opening a short distance above the papilla of Vater, or it may connect with the main duct. Sometimes it is of large size and may serve as the chief excretory duct of the gland. Anomalies of the pancreas are occasionally seen, such as division of the organ into two parts connected by a thin bridge of gland substance containing the duct, or an accessory pancreas may be found in one-half to one per cent of the cases. This is a mass of gland tissue with a duct opening into the alimentary canal and lying in the wall of the stomach, duodenum, or other portion of the small intestine. In the embryo the pancreas is developed from two distinct entodermal outgrowths from the wall of the duodenum and the junction of the bile duct with the duodenum respectively, spoken of as dorsal and ventral buds, the latter of which is double. The dorsal portion, which is much larger than the ventral, forms the body and the tail of the gland, and also a part of the head. It contains the duct of Santorini, but the larger part of the dorsal pancreatic duct joins the duct of the smaller ventral pancreas and gives rise to the main excretory canal of the gland, the duct of Wirsung. In structure the pancreas resembles the parotid gland, and for this reason is sometimes termed the abdominal salivary gland. It belongs to the group of tubulo-racemose glands and consists of groups of secretory cells or lobules held together by a stroma of loose connective tissue,

which also carries the ducts, vessels and nerves of the organ. In the lobules two types of cells may be distinguished, the secreting cells, which make up the bulk of the organ, and groups of cells of a different type found in the centre of the lobules, which were first described by Langerhans in 1869, and are called pancreatic islands. The secreting cells, when at rest, contain coarse granules which disappear when the gland is actively secreting. The islands of Langerhans, which vary in size from a few cells to several millimeters in diameter, develop from the smaller ducts after the gland has attained a considerable degree of development in the embryo. They are composed of spheroidal or polygonal cells, distinct in appearance from the secreting cells, and produce an internal secretion which is discharged directly into the blood vessels. The external secretion, or pancreatic juice, plays an important part in the digestion of proteins, fats and carbohydrates (see article DIGESTION). It is a clear, alkaline fluid of which it is estimated that from 16 to 26 ounces (500 to 800 cubic centimeters) a day are secreted. Its most important constituents are three enzymes, or their preliminary forms, called zymogens, namely a protein-digesting enzyme, called trypsin, a starch-digesting enzyme called amyl-opsin, and a fat-digesting enzyme called steapsin (lipase).

The mechanism of secretion is supposed to be as follows: When food leaves the stomach and enters the duodenum, the acid of the gastric juice produces from the mucous membrane of the intestine a substance called secretin. This is absorbed by the blood and is carried to the pancreas which it stimulates to activity, though the secretion is also to some extent under the control of the secretory fibres of the vagus and splanchnic nerves. The pancreas furthermore produces an internal secretion which is apparently formed by the cells of the pancreatic islands. This is thought to be essential for the proper metabolism of sugar in the body, and in diabetes (see article DIABETES) these portions of the gland usually show more or less degeneration or shrinkage. The view now held is that sugar exists normally in the body in a combined form, but that in diabetes this power of combining is to some extent lost and the combining substance which forms the bond between the tissues and the sugar is supposed to be supplied by the cells of the pancreatic islands. Besides the changes observed in diabetes, there are numerous other forms of disease of the pancreas. Among these may be mentioned acute or chronic inflammatory changes (pancreatitis), cysts and tumors. Of the latter, cancer is one of the commonest, and is generally secondary to a similar growth in the stomach. The symptoms of these conditions comprise pain (usually high up in the abdomen), digestive disturbances, the passage of bulky, light-colored, fatty stools, jaundice, loss of weight, etc. A characteristic manifestation, known as fat necrosis, is sometimes seen in which as the result of the escape of pancreatic secretion into the surrounding fatty tissue areas of necrosis develop owing to the action of the fat digesting ferment.

PANCREATIN, a substance secreted by the pancreas, and often administered in medicine for the correction of certain digestive disorders. The commercial supply that is used in

medicine is mostly obtained from the pancreas of the hog, and is best known in the form of a grayish, amorphous powder, usually with a tinge of yellow, and with a faint, characteristic smell. Pancreatin is not a definite chemical substance, but contains several distinct ferments. Its composition varies, moreover, with the source from which the substance is prepared, and with the state of activity of the particular pancreas from which it is extracted. One of its normal components, steapsin, is an exceedingly powerful agent for effecting the emulsification of fats, and it is even able to partially separate them into free glycerin and free fatty acids. Another constituent, trypsin, converts coagulated albuminous substances into soluble peptones, resembling pepsin in this respect, although its action is somewhat different. Pancreatin, for example, is effective only in an alkaline medium, while in the case of pepsin the medium must be acid. Another constituent, amyl-opsin, converts starches and other amylaceous substances into sugars; and a fourth ferment that is present possesses the power of coagulating the casein of milk.

PANDA, or **WAH**, an animal (*Ælurus fulgens*) of the raccoon family, which inhabits the eastern Himalayas to a height of about 12,000 feet. It is equal in size to a large cat, and has remarkably glossy reddish-chestnut fur, darker below, with a white face and a long ringed tail. It seems to be the remnant of a once very widespread group which in the early Tertiary Period was numerous in Europe, explaining the present curious distribution of the family, for all other existing raccoons are American. The animal is described as inhabiting forests and feeding almost entirely on vegetable food; but it eats eggs and insects when it can get them. Most of its time is spent upon the ground, but it has semi-retractile claws and is able to climb trees. It is said to be rather a dull-witted, defenseless creature, reminding one of the kinkajou. Consult Flower and Lydeker, 'Mammalia' (1891); Blanford, 'Fauna of British India: Mammals' (1888).

PANDAN, pān-dān', Philippines, a pueblo of the province of Antique, island of Panay, on the west coast near the Bugang River, 66 miles north of San José de Buena Vista. It is on the coast road and has a good anchorage ground. Pop. 13,800. There is a small pueblo of the same name (pop. 2,143) on the north coast of Catanduanes Island, near Albay, Luzon.

PANDANUS. See SCREW-PINE.

PANDARUS, pān'dā-rūs, Trojan hero, son of Lycaon. He was given by Apollo a bow with which he became famous as an archer. In the war between the Greeks and Trojans he broke the truce, and after wounding Menelaus and Diomedes was slain by the latter. He also appears in Shakespeare's 'Troilus and Cressida' as a procurer, whence the English word "pander."

PANDAVAS, pān'dā-vaṣ. See MAHÁBHĀRATA.

PANDECTS, *The*, the most important compilation of the Roman law, prepared by several scholars at the order of the Emperor Justinian (q.v.). It is also called 'The Digest.' It was an attempt to form a complete system of law from the commentaries of the great

jurists. The work was done by a committee composed of the jurist Tribonianus and 16 others learned in law; it was begun in 530 A.D. and completed in 533. The magnitude of the task becomes apparent from the fact that about 2,000 various treatises were consulted, and from these about 9,000 extracts appear. One-third of them comes from Ulpian, one-sixth from Paulus, one-twelfth from Papinianus, and the rest from 36 other writers. The Pandects, with the Codex Justinianus, became the law for the Roman Empire. When the Lombards invaded Italy in 568, they overturned almost all the few remaining Roman institutions, the law courts among them. In Ravenna, however, the Roman law was still taught; and the Lombards allowed their Roman subjects to be judged according to the Roman law. The Codex, which begins with an invocation to the Trinity, and contains a great deal of legislation on ecclesiastical matters, was held in esteem by the clergy; but the Pandects were at first ignored as being the work of pagan jurists. In the last part of the 11th century, however, there was a great revival of the study of Roman law. Irnerius of Bologna, the greatest teacher of his time, renewed the study of the Pandects, which, together with the Codex, became the basis of all mediæval legislation. The Pandects may justly be considered the most famous collection of law ever made. In both its central idea of codification and its content and phraseology it has profoundly influenced subsequent legislation, including that of New England and the United States.

PANDORA, in Greek mythology, the first woman; so called because she received gifts from all the Olympians. She was the creature of Prometheus, and the gods came down to see her and conferred their gifts on her. Athena instructed her in all works of female skill. Aphrodite endowed her with beauty and fascination. Hermes inspired her with a desire of pleasing, and taught insinuating words. Athena carried her thus equipped into the assembly of the gods, and all admired the work. She became the wife of Epimetheus, a mortal, brother of Prometheus, and brought sorrow into the world by opening, in her curiosity, a box containing the blessings of life; all these escaped, save Hope. This is clearly a late and philosophic addition to the myth.

PANDOURS, pân'doorz, or **PANDOORS**, the name formerly given to the Servian or Raitzian irregular foot-soldiers coming from the village of Pandur, in the county of Sol, in Lower Hungary, who in 1750 were made regular troops. The term is now used in Hungary and Croatia for mounted constabulary or guards.

PANEL, (1) *in law*, a schedule, or roll of such jurors as the sheriff returns to pass upon any trial; and impaneling a jury is returning their names in such schedule of parchment. In Scottish law the prisoner at the bar is the panel. (2) *In carpentry*, a tympanum or square piece of thin wood, sometimes carved, framed or grooved in a larger piece, or between two upright pieces and two cross pieces. (3) *In masonry*, a face of hewn stone. (4) *In bookbinding*, a depressed part of the sides within a relatively elevated bordering portion; or a space on the back between bands. (5) *In mining*, a system of coal mining in which the projected

winning is divided into large square allotments, divided by massive walls of coal, instead of placing the whole working in one undivided arrangement. The pillars are left very large, the room small; the pillars are worked out, props being substituted; these are knocked out, and the goaf filled up by the caving down of the ceiling. (6) *In painting*, a piece of wood — oak, chestnut or white poplar — on which, instead of canvas, a picture is painted. The earliest paintings in oil were generally executed on panels, which were composed of various pieces of wood, cemented together with cheese glue; and this glue, or cement, caused each portion to adhere so firmly that such panels were considered stronger than those which consisted of one piece of wood only.

PANGASINÁN, pân-gä-sē-nân', Philippines, a province of the Island of Luzon, in the western central part of Northern Luzon at the head of the Gulf of Lingayen; length, east and west, 56 miles; width, 33 miles; area, 1,316 square miles. The province is mountainous in the northeast, and also near the western boundary; the rest of the surface is flat, sloping toward the sea, and near the coast is very low and frequently inundated by the rivers. There are numerous rivers, of which the Agno is largest and most important. The staple crop is rice, though this is often injured by floods; sugar, corn, tobacco and cocoanut are also abundantly cultivated; the nipa palm grows luxuriantly. There are abundant deposits of salt, and also gold, copper, iron, magnetite and sulphur. The important industries beside agriculture include the making of nipa wine, the weaving of buri and manufacture of mats, hats and sacks, and boat building. The Gulf of Lingayen affords excellent commercial facilities; the commerce is carried on almost wholly by the Chinese. Many of the rivers are navigable for some distance; well constructed roads extend all over the province, and the Manila and Dagupan Railroad also crosses the province. Pop. 343,686, mostly Pangasináns.

PANGASINÁNS, a group of tribes of the Philippine Islands inhabiting the province of Pangasinán, Luzon and some localities in the province of Zambales, Nueva Ecija and Benguet. They are of the Malay race, and at the time of the arrival of the Spaniards had a civilization and written language of their own. Their language is now generally spoken in the province of Pangasinán. They are Christians.

PANGE LINGUA GLORIOSI CORPORIS MYSTERIUM, the first line of one of the finest of mediæval hymns, composed by Saint Thomas Aquinas (d. 1274) for the Office of Corpus Christi. The metre and the opening line are imitated from Venantius Fortunatus, and the poem itself consists of six stanzas of three lines each with triple rhyme in the middle and at the end. In the Roman Breviary, however, it is divided into stanzas of six lines each by halving each of the original lines. This hymn is sung in the solemn procession to the Repository on Maundy Thursday, also in the procession of Corpus Christi and of the Forty Hours Devotion. Stanzas 5 and 6 (stanza 6 forms the doxology) are sung as a special hymn (Tantum Ergo) and prescribed for the Benediction of the Most Blessed Sacrament. Critics have been unanimous in their praise of

this work of Saint Thomas. Pimont says that the alternating triple rhyming is a new feature in mediæval hymnody. Neale declares that "this hymn contests second place among those of the Western Church with the 'Vexilla Regis,' the 'Stabat Mater,' the 'Jesu dulcis memoria,' . . . and one or two others, leaving the 'Dies Iræ' in its unapproachable glory." Duffield goes farther and says that "it excels all these" in "its peculiar qualities, its logical neatness, dramatic precision, and force of almost argumentative statement." Translations of this hymn have not been many or felicitous (consult the 'Dictionary of Hymnology'), the best ones perhaps being those of Wackerbarth, Caswall, Neale and Donahoe. A fine rhymed translation, preserving the metre of the original, was published with the text and notes by Hugh T. Henry in the *American Ecclesiastical Review* (March 1890).

HERBERT F. WRIGHT.

PANGE LINGUA GLORIOSI PRÆLIUM CERTAMINIS, the first line of a hymn generally credited (e.g., by Dreves, Mearns and others) to Venantius Fortunatus (6th century), although sometimes ascribed (e.g., by Gerbert, Bähr Pimont) to Claudianus Mamertus (5th century). In the manuscripts, several of which go back to the 8th century, the hymn contains 10 stanzas (excluding the closing stanza or doxology) of three lines each (tetrameter trochaic catalectic unrhymed). In the Roman Breviary, the hymn is assigned to Passion Sunday and ferial offices from then to Wednesday in Holy Week, also to feasts of the Finding of the Holy Cross, of the Exaltation of the Holy Cross, of the Crown of Thorns and of the Five Wounds. In this Breviary, the hymn is divided into two, the first five stanzas being said at Matins, the second five at Lauds; and each line is subdivided into two so that the stanza contains six lines. The entire hymn is sung on Good Friday during the Adoration of the Cross, immediately after the "Improperia" or "Reproaches." This hymn, like the "Vexilla Regis," suffered many emendations (e.g., "lauream" was substituted for "prælium" in the first line) at the hands of correctors of the Breviary under Urban VIII. The corrected form remains to-day in the Roman Breviary. The more notable translations (consult the 'Dictionary of Hymnology') are those by Aylward, Caswall, Campbell and by Neale. A fine translation, preserving the metre of the original, was published with the text and notes by Hugh T. Henry in the *American Ecclesiastical Review* (March 1891).

HERBERT F. WRIGHT.

PANGENESIS, a theory advanced by Darwin to account for the phenomenon of heredity, and especially to explain the (alleged) inheritance of acquired characters (effects of use and disuse of parts) which formed the basis of the theory of evolution of Lamarck. (See LAMARCKISM). The problem was to form a hypothesis by which changes in any part of the body could so affect the germ-cells that the parental peculiarities should reappear in succeeding generations. Darwin supposed that every cell of the body gives off at every stage of its existence minute particles, or gemmules, which when furnished with proper nutriment will give rise to parts similar to those from which

they were derived. These gemmules are collected from every part of the body to form the sexual elements, and their development in the next generation forms a new being. To explain the fact that characters may skip a generation, he assumed that the gemmules may lie dormant for a time. This theory was weak in that it assumed the existence of particles of which we have no other evidence, and it was shortly disproved by Galton. If these gemmules are constantly given off they must be carried by the blood, and hence if introduced into another animal they must affect the progeny. Galton introduced into the blood of silver-gray rabbits the blood of rabbits of other colors, in some cases to the extent of half the blood, but the offspring invariably showed no trace of change of color. Brooks in his 'Heredity' (1883) modified the theory so as to avoid Galton's experiment, but the theory has been dropped in later years, and has only a historic interest. Consult Darwin, 'Variation of Animals and Plants under Domestication' (1868), and the authorities mentioned under HEREDITY.

PANGO-PANGO, päng'gō-päng'gō, or **PAGO-PAGO**, a harbor on the south coast of the island Tutuila, Samoa. It is L-shaped, with the greatest length (17 miles) from east to west. It is land-locked, and in every way one of the finest harbors in the Pacific. It was ceded to the United States as a naval and coaling station in 1872, and the cession was confirmed by a treaty signed in 1878, by which the United States was given the right to establish at the harbor a station for coaling, naval supplies, freedom of trade, commercial treatment as a favored nation, and extra-territorial consular jurisdiction. It was occupied by the United States in 1898, with the purpose of utilizing its advantages as a coaling and supply station; and by the agreement of 1899, the island of Tutuila came into the possession of the United States. See SAMOAN ISLANDS.

PANGOLIN, or **SCALY ANT-EATER**. See MANIS.

PANGUTARÁN, päng-oo-tä'rän, a group of small islands of the Sulu Archipelago, lying in the Sulu Sea, south of the Philippines and 100 miles or more northeast of Borneo. The group includes 13 islands of which the two largest are Pangutاران, 44 square miles, and Panducan, 14 square miles; the area of the whole group is 72½ square miles. The islands are moderately high, and are very heavily wooded. The chief industries are fishing and agriculture which is carried on in the rudest and most primitive manner. The island of Pangutاران is low and level; it is thickly populated and carries on a considerable trade with Sulu.

PANHANDLE, The, a long, narrow strip of land, resembling the handle of a pan, generally projecting from a State or Territory, as the Panhandle of West Virginia, or the Panhandle of Idaho. There is also a well-known projection in Texas called the Panhandle.

PANIC, in finance, and commerce, a period of numerous business failures and reduced values, causing loss of confidence by the public, and denoting insecurity and danger to money values and credits. When a panic occurs the banks are besieged by depositors, money is hoarded and

general financial distrust ensues. The most noted financial panics since 1750 were as follows:

- 1763. Amsterdam. Heavy failures in Holland, England and Hamburg.
- 1773. Holland. Failures exceed \$50,000,000.
- 1793. England, owing to French war. Government issued \$25,000,000 Exchequer bills.
- 1799. England. Panic at Liverpool. Government lent \$2,500,000 in Exchequer bills on goods.
- Eighty-two failures at Hamburg.
- 1814. England. 240 banks stopped payment.
- 1825-1826. England. 770 banks stopped payment owing to failure of South Sea bubble companies. Owing to the distress occasioned by the consequences of this panic, families in Yorkshire were reduced in 1829 to live on bran. From the same cause about 200,000 families emigrated to the Continent, America, etc., in four years.
- 1831. Calcutta. Failures, \$75,000,000.
- 1837. United States. "Wild Cat" crisis.
- 1847. England. Owing to excessive railway speculation. Failures, \$100,000,000. Discount rate, 13 per cent.
- 1857. United States. Failures \$555,000,000. Minor crisis in England.
- 1866. London. Owing to over-speculation. Total failures above \$500,000,000. The last of the serious panics.
- 1873. United States. Heavy failures in New York and elsewhere.
- 1884. Grant and Ward and Marine Bank failures.
- 1885. London. Much temporary disturbance owing to expected Russian war.
- 1890. London. Baring crisis. Liabilities guaranteed by English banks.
- 1892. Financial crash in Australia.
- 1893. United States. The silver crisis, also by some attributed to fear of changes in tariff by the Democratic party.
- 1907. United States. Crisis brought about by reckless speculation and improper management of financial institutions.
- 1914. Worldwide, due to the war.

Financial panics and their causes have been the subject of interminable discussion, controversy and theory. They occur with a degree of regularity, and appear to follow certain rules. While undoubtedly artificial, growing out of the established monetary systems and methods of credit, yet once a panic is on, it seems to have to run its course, and business men and financiers shape their affairs to meet the conditions. One of the theories of regularly recurring panics is under-consumption, growing out of the fact that in modern business the money has to go through the pay-rolls to be spent and returned to the banks, and since profits are taken off most transactions, it follows that all of the money is not returned to circulation, and this scarcity of money tends to increase, and after some years hard times and panic follow. Another theory is the changing value of gold, on which we base all financial transactions. Increased production of gold may or may not keep pace with increased commerce and commercial activity, and when a disproportion develops some people suffer, and panic ensues. Alternate inflation and contraction of currency seems a sure cause of financial panic. Banks are allowed to issue paper money under certain conditions safeguarding the public; they issue much more than can be redeemed in coin. There is further inflation by checks and notes, until it has been customary to report banking deposits as five or six times the total coin in a country. Then something happens to tie up a lot of money, and everybody is short, and postpones paying bills, so that weak business houses fail and drag down others with them; a period of contraction has set in; stocks tumble in value; speculations push them further down; rentals reduce and real estate values fall, wages and prices are lowered and several years

of hard times usually follow. The doing of large business through stock companies, whose securities constitute a convenient form of investment, is regarded as another prolific source of panics. The man who is pinched throws his stock on the market, and the more there is thrown the lower it goes; the speculator sells short and the public loses faith in that stock, when there is absolutely nothing wrong with it, only with the holder who cannot carry it. Stocks are also used to build up fictitious values on temporary earning power, and when the interest is reduced there is more tumbling of values. It is apparent that the monetary system of the world needs revision, but just how has never been made clear. Possibly the violent strains put upon financiers during the World War, and the experiences undergone may result in a bettering of methods, so that panics will be a thing of the past. That money panics are properly named is evident from the way in which the various great financial centres of the civilized world have withstood the shock of the World War. At first it appeared so unparalleled a calamity that it was doubted if the soundest financial institutions could survive the certain heavy drains for cash. The pressure was felt first in Austria, where the Vienna Exchange closed 27 July 1914. The Berlin and Paris exchanges followed, while the London and New York stock exchanges closed on the morning of the 31st. During the four days, stocks in New York had declined about 10 points on the average, and a deluge of selling orders was imminent. So the governors decided that closing the exchange was the only course open. In the meantime the rate of discount was advanced from day to day, and on 1 August the Bank of England fixed it at 10 per cent.

The moratorium was invoked to save the situation. The British government declared it in existence on 4 August for 30 days, applicable to long term bills of exchange; this was later extended so that it lasted three months. France, Russia, Austria-Hungary, Italy and practically all European countries followed this precedent, and established a moratorium lasting several months, while Germany covered the situation by ruling that foreign balances could not be sued for under three months. In the United States there was a general extension of time on all classes of indebtedness. The English banking system had to bear the principal weight of the first blow, being the "world's banker," and creditor of banks and large mercantile houses all over the globe. At first gold passed into London, but later the tendency was toward the United States, owing to the heavy expenditures here for war materials. Rediscounting was resorted to, and saved the situation, these rediscounts being treated as cash deposits. The British government stood back of the rediscounts of the Bank of England, and this gave universal confidence and prevented runs on the banks. The German financial situation was handled in much the same way, the discounts being extended as the situation demanded. Conditions in the United States at the outbreak of the war in July and August 1914 were better for resisting a panic than ever before. The system of Federal Reserve Banks (q.v.) established in 1913, was just ready to

go into operation, and was admirably adapted to rediscounting, in fact it was designed to meet just such emergencies, though no one had anticipated such immediate need. The banks had the power to increase their circulations under the act of 1908, and thus conserve their gold, and this was immediately taken advantage of. The national banks of New York City increased their currency notes about \$100,000,000 the first month of the war. On 16 Nov. 1914, the 12 regional banks were opened for business, and rediscounting was carried on easily. These exceptional experiences seem to point the way for preventing in the future most of the evils of great financial panics. It is likely that periods of commercial depression will come again, but the banks of all countries now know how to meet such emergencies, and protect each other, while governments are inclined to stand back of the banks.

PANINI, pā'ni-nī, Indian philologist: b. Salatura (near modern Attock), Punjab, 4th century B.C.; probably the oldest writer on grammar whose works are extant, although he quotes the names of 64 predecessors. He is reckoned among the sages of the Puranas. Nothing is known of his life. His grammar is in eight books, divided into chapters, and containing 3,996 rules or sutras. Its method is wholly different from that of European grammarians. The separate chapters treat the various phenomena of language as they appear in all the various forms of speech; hence the work is strictly a philosophical treatise, requiring to be studied as a whole, and not conveying sectional information in a form classified for reference according to the European model. His style is condensed, obscure and difficult to the Western student. He is the first who has classified the philological principles of grammar, as distinguished from the mere forms or parts of speech. He did not treat of syntax, and inflections are not formally given, but must be obtained by a collation of separate rules. The grammar of Panini has been often annotated. Its chief critic is Patanjali (q.v.). The chief edition of Panini is by Bothlingk (1887), and that of Patanjali's 'Great Commentary' by Kielhorn (1878-85).

PANIPAT, pān-i-pūt', or **PANIPUT**, India, town in the district of Karnal, Punjab, about 52 miles north of Delhi, on the Grand Trunk and the East India railroads. It is a strategic centre and was the scene of the negotiations of Duryodhana and Yudisithira at the beginning of the 12th century B.C., of the Mogul victory of Baber over Ibrahim Lodi, which established the Mogul power in North India in 1526, of Akbar's victory over the Afghans in 1556, which reassured the existence of the Mogul Empire, and of the Afghan victory of 1761 over the Maharrattas, which prepared the way for English rule. It exports a coarse sugar.

PANITAN, pā-nē-tān, Philippines, a pueblo of the province of Cápiz, island of Panay; on the Malinannang River, seven miles south of Cápiz, the provincial capital. Pop. 10,020.

PANJAB, pūn-jāb', **PUNJAB**, or **PUNJAUB**. See **PUNJAB**.

PANJANDRUM, the name applied to an imaginary personage of power and influence; a

burlesque monarch or Great Mogul. The word was originally coined by Samuel Foote in a long string of rigmarole as a test for Macklin, who boasted of his memory. It is also called the Grand Panjandrum.

PANJIM, capital of Goa, Portuguese India.

PANJNAD. See **PUNJNUD**.

PANKHURST, Mrs. Emmeline, English "suffragette" leader: b. Manchester, 1854. She was educated in Paris and married in 1879 to Dr. Richard M. Pankhurst, who had been a member of the first woman suffrage society, founded by John Stuart Mill. She later served on the committee for promoting the Married Women's Property Bill, which was originally drafted by Dr. Pankhurst and subsequently became law. In 1886 Mrs. Pankhurst joined the Fabian Society in London and the Holborn Women's Liberal Association; she seceded in 1892 and became a member of the Independent Labor Party, running as its candidate for the Manchester School Board, though unsuccessfully. In 1893 she was elected a poor law guardian of Manchester, serving five years. On the death of her husband in 1889 she was appointed registrar of births and deaths. Together with her daughter Christabel she founded, in 1903, the Women's Social and Political Union (W.S.P.U.) and two years later inaugurated her well-known campaign of violent suffragism. On 13 Feb. 1908, she headed a deputation of 13 women to the House of Commons, thus starting a three days' riot, for which she received six weeks' imprisonment. In October she faced a similar charge and with her daughter was sentenced to three months, but was released before expiry of the term. In 1909 she conducted a lecturing tour in the United States and Canada. She led another deputation in 1910 to the Prime Minister, Mr. Asquith, who refused to see her. Four days later she marched on the same errand at the head of some hundreds of women. She was again arrested, but discharged. In March 1912 many of her followers, armed with hammers, indulged in an extensive window-breaking campaign among the West-end stores. With two others she drove to Downing street and threw a stone through a window, which resulted in two months's imprisonment. On 5 March the W.S.P.U. headquarters were raided by police, when Miss Pankhurst escaped to France. Within five days 124 women were arrested and Mrs. Pankhurst was sentenced to nine months' imprisonment for conspiracy. She adopted the "hunger strike" and was released on 24 June. Meanwhile, her example animated her followers to continue the campaign of outrages. A bomb was placed in the Home Secretary's office; attempts were made to fire the residences of ministers and the Theatre Royal in Dublin, where a hatchet thrown at Mr. Asquith struck the late Mr. Redmond instead. Acid was poured into letter-boxes throughout the country and much mail matter was destroyed. During January 1913, 50 women were arrested for window smashing; windows were broken in Lambeth Palace and in the Jewel Room at the Tower of London; hundred of orchids were destroyed at Kew Gardens, where a tea pavilion was also burned down; golf links were damaged; a house in course of construction for Mr.

Lloyd George was burnt at Walton Heath; railway stations were set on fire; several mansions, racecourse stands and a church were destroyed; the historic Smeaton Tower at Plymouth was attacked and a bomb placed in Saint Paul's Cathedral. Mrs. Pankhurst openly accepted the responsibility and declared herself the instigator of these acts. On 3 April 1913 she was sentenced to three years' imprisonment. Owing to "hunger-striking" she was several times released and rearrested, and finally discharged on 24 July. Her militant policy alienated much sympathy from the cause of woman suffrage. During the European war she devoted her energies to work of a useful, national character, in the course of which she visited Russia and America, while her second daughter, Sylvia, was arrested and sentenced in Australia for political agitation.

HENRI F. KLEIN,

Editorial Staff of The Americana.

PANMIXIA, in the theory of organic evolution, the cessation of the operation of natural selection. The process of the survival of the fittest, says Parker, has a reverse side, which has been termed the elimination of the unfit. Of the varieties that appear, some are less completely adapted to their surroundings than the majority, and these (the conditions remaining the same) tend to become destroyed owing to their unfitness to cope with their environment. The result of this process of elimination (apart altogether from the selection of progressive variations by which evolution, according to the theory, proceeds) is to keep up a certain standard of efficiency in the organs of the members of the species. Under certain conditions this *sustaining* influence, as we may term it, of natural selection may be suspended; the organism may be placed under conditions in which natural selection acts with reduced effect or does not act at all. There is, under such circumstances, no "elimination of the unfit"; and, as a result, fit and unfit survive indiscriminately, inter-breed and produce offspring, the ultimate outcome in the course of generations being a gradual deterioration in the whole race.

This suspension of the influence of natural selection or *panmixia* acts more commonly on single organs than on the entire organism. Thus if, owing to some change in surrounding conditions, an organ is no longer kept up to the previous degree of efficiency by the elimination of the individuals in which the organ in question is imperfectly developed, and, as these cross with one another, offspring is produced in which the organ is below the efficient standard; and by a continuance of this process through a series of generations, it is supposed that the organ gradually dwindles in size, and may altogether disappear. The cetaceans furnish good examples of the process. Consult Parker and Haswell, 'Text-book of Zoology' (1897).

PANNINI, pan-nē'nē, Giovanni Paolo, Italian painter; b. Piacenza, 1695; d. 1768. He studied under Luti and Lucatelli in Rome. His work was limited to interior and exterior decoration in Rome and its neighborhood and is of a very high order. His 'Interior of Saint Peter's' and 'Old Ruins' now repose in the Louvre and the National Gallery, London, contains 'The Pyramid of Cestius' and the New York Metropolitan Museum contains 'Cardinal

Polignac Visiting Saint Peter's.' Other examples of Pannini's work are housed in Naples, Florence, Madrid, Vienna and London. The Quirinal contains some frescoes by him.

PANNONIA, pa-nō'ni-a, in ancient geography, a Roman province on the Danube, including what is now western Hungary, Slavonia and Bosnia, eastern Austria and Styria. Neither the origin of the name nor of the inhabitants, the Pannonians, is anything certain known, but the people may have been of Illyrian stock with an admixture of Celtic due to a Celtic invasion in the 4th century B.C. They were conquered by the Dacians about 50 B.C. Octavian defeated them in 35-34 B.C., but they rose a generation later and Pannonia was finally conquered in 9 A.D., but not occupied save on the frontier until 102-107 A.D., by Trajan. The principal cities planted by the Romans were Vindobona (Vienna), Carnuntum (near Deutsch-Altenburg), Savaria (Szvobathely), Arrabona (Raab), Siscia (Sissek), Poetovio (Pettau), Aquincum (Altöfen), and Sirmium (Mitrovitza). Trajan divided the province into a lower and an upper Pannonia. In the beginning of the 5th century Valentinian III of the Western Empire ceded Pannonia to Theodosius II of Byzantium, who surrendered it to the Huns. It was occupied by the Ostrogoths about 450 A.D., by Theodoric of Italy in 488, by the Lombards in 527 and by the Avars in 568. Then came the influx of the Slavs.

PANO (pā'nō) **INDIANS**, a South American tribe living along the banks of the Ucayali and Huallaga rivers in Peru. They were formerly very numerous but now number less than 2,000. During the 17th century the missionaries persuaded many of them to gather in the mission villages. They were of a rather low grade, but understood hieroglyphic writing on bark. When the missions were broken up, in 1767, most of the Panos returned to their savage life, forming numerous small tribes. They have always been friendly to the whites. They are expert boatmen and build canoes some of which are 40 feet in length.

PANOAN INDIANS, a South American family comprising upward of 20 tribes and occupying the forest regions of Peru, Bolivia and Brazil. Among the better-known tribes are Cashibo, Conibo, Mayoruna, Pano, Remo and Setebo. They are a savage race in all that the name implies and several of the tribes practise cannibalism. They have steadily decreased in number during recent years.

PANORAMA, a picture representing a wide or general view, as of a large tract of country, so exhibited a part at a time by being unrolled and made to pass continuously before the spectator. It was invented in England in 1787 by Robert Barker. See also CYCLORAMA.

PANPIPE, an ancient wind instrument, the precursor of the organ (q.v.). It was formed of seven, eight or nine short hollow reeds, fixed together by wax and cut in graduated lengths so as to produce a musical scale. The lower ends of the reeds were closed and the upper open and on a level so that the mouth could easily pass from one pipe to another.

PANPSYCHISM (Greek *pan*, all, and *psyche*, soul), the theory that all things are essentially of a mental nature. In other words,

it is the theory that all the phenomena to which we are accustomed to attribute a purely physical character are really associated with or constituted by minds of their states or perceiving, feeling, willing and reasoning. It is foreshadowed in the animism (q.v.) which precedes natural science, in which every natural occurrence such as the falling of rain, the motion of the sun and stars, or the growth of plants, is interpreted in anthropomorphic terms. In this stage of civilization, however, instead of an actual assertion of the existence of a psychical aspect in every physical occurrence, there is merely a lack of distinction between mind and matter. True panpsychism crystallizes out in Greek philosophy, as the original hylozoism becomes conscious of itself. The interpretation of the world in terms of form and identification of this form with idea is the essence of Platonism. This idea, it is true, is not in any individual consciousness; in Neoplatonism, however, the ideas of particular things come to be emanations from the one mind that is conscious of them—that is, the quasi-divine idea of the good. Stoicism (q.v.) also draws the necessary conclusion of panpsychism from its two theories of pantheism and of the psychical nature of God. This type of panpsychism is characteristic of many forms of European and Oriental mysticism. However, the name panpsychism is often confined to a different type of theory, which is due to Leibnitz. Here the mental nature of matter does not consist merely in a substantial unity between thought and its objects but in the existence of concrete acts of perception or feeling or of mental states of a lower (though yet definite) level, inseparable from every physical phenomenon. In the philosophy of Leibnitz the material world consists in an aggregate of dimly perceiving and dimly perceived monads or souls. Fechner combines a strict parallelism of mind and body with a pantheism and a belief in the omnipresence of mind. Clifford develops an atomism in which both mind and matter are built up of units of mind stuff. Clifford's theory is known as the mind-stuff theory. It is very like certain forms of present day empirical realism, in which sense-data and their relations are supposed to build up mind indivisibly in physical atoms and psychical monads, qualitatively determined by the latter, and finding its most advanced expression in the intelligence of the higher animals. In this theory all matter is composed of elements, essentially psychical, internally—mind, externally—matter. Consult Clifford, W. K., in Vol. III, *Mind* o. s.

PANSLAVISM, a general name for the efforts of the Slavonic races in Europe for a unity of civilization and literature. An anonymous work, the 'European Pentarchy' (1839) and the writings of A. Gurovski, made a considerable impression in favor of a union under Russia; while later events favored the Austrian headship; but none of these projects ever possessed a reasonable chance of realization. The mere fact that the Slavonic race comprises nations so bitterly hostile as Russia and Poland, not to speak of geographical and political difficulties, and of such diversities of religious creed as are contained with the range of Christianity and Mohammedanism, made any attempt to unite the

scattered elements of such a race in a voluntary political union impracticable.

The most important effort put forth toward the realization of a political union of the Slavs was in 1848, when, stimulated by the rival efforts at union of the German nations and especially by the summons to Bohemia to send her full contingent to the German Parliament, the Slavonic clubs summoned a congress of all the Slavs in the Austrian Empire, with a view to confer on the constitution of the empire. The congress met at Prague on 2 June. The various nations represented were classified in three departments: the first, consisting of the Bohemians, Moravians, Silesians and Slovaks or Western Slavs; the Poles and Ruthenians forming the Eastern Slavonians; the Slovenians, Croats, Serbians and Dalmatians the southern division. Each of these divisions chose 16 members, who formed a committee, with Palacky at their head, who drew up a plan of confederation and alliance among the various nationalities of the empire. The proceedings of the congress, however, which had to be conducted in German as the only common means of communication, could not be brought to a formal conclusion and the congress was interrupted by a Slavonic insurrection, which proved futile. After 1866 renewed but unavailing efforts were made by the scattered Slavonians of Austria to form a union among themselves, in order to counterbalance the preponderance of the German and Magyar races.

A great Slavonic congress held at Moscow in 1867 was also practically fruitless. An important product of Panславism, however, is the work of its numerous scholars and authors in literature and philology, formulating exact principles for a comparative science of the Slavic tongues. Foremost in fostering the intellectual growth of Slavonic aspirations was Archbishop Joseph George Strossmayer (q.v.), who founded the South Slavonic Academy in 1867, Agram University in 1874 and was largely instrumental in reorganizing the entire educational and religious system of the Austro-Slavonic regions. (See **BOHEMIAN LANGUAGE**; **CZECH LITERATURE**). Due to the initiative of Czechs and Poles, a second Congress of Slavic nations was held in Prague in 1908, when resolutions were passed in favor of Slavic unity. The Russo-Turkish War of 1877-78 originated in the undercurrents of Panславism, as also the Balkan Wars of 1912 and 1913, while they contributed to the Great European War of 1914-18 the assassination of the crown prince of Austria which precipitated the conflict. For further developments of Panславism see **BOHEMIA**; **CZECHS AND CZECHO-SLOVAKS**; **RUSSIA**; **SLAVS**; **WAR, EUROPEAN**. Consult Levine, L., 'Pan-Slavism and European Politics' (New York 1914); Vrba, R., 'Russland und die Panславismus' (2 vols., Prague 1913).

PANSY, an annual or imperfectly perennial herb (*Viola tricolor*) of the family *Violaceæ*. It is a native of Europe where it has been in cultivation for at least 400 years, and whence it has been taken to all cool temperate climates of the civilized world. The plant, which is rarely more than six inches tall, bears long-petioled, heart-shaped leaves and large irregular flowers which slightly resemble the human face. Its name is a corruption of the

French, *pensée*, thought, and its old folk-name, "heart's ease," signifies remembrance, a double reason for its popularity. Few flowers show the effects of care in selection more than the pansy. Naturally the blossoms are borne upon rather short stalks and are less than a third the size of improved varieties, which often attain a diameter of three inches. In dry climates fresh seed must be imported annually, since home-grown seed, even of improved strains, is apt to produce flowers inferior to the imported, each year emphasizing the deterioration. The cultivated pansies are grouped in strains rather than as individual varieties, and as a rule exhibit mixtures of blue, white and yellow, although some kinds are all of one color. Pansies thrive best upon rather heavy loams well drained and well supplied with plant food and humus. In the United States and other countries where the air becomes very dry during the summer, the plants generally fail during the hot months, even when planted in shady places, the most favorable situations. Hence, in such climates the seed is usually sown in cold frames during August or September, kept cool and moist by a rather thick mulch of loose straw until the plants appear, and then these are protected from drying winds. Being tolerably hardy the plants can be left in the frames during winter, previously having been transplanted from the seed-bed so as to stand about two inches apart. In the spring they may be allowed to blossom where they stand or may be transplanted to garden beds as soon as the ground can be worked. After flowering in these beds for a month or six weeks they should be replaced by geraniums or other heat-loving plants.

PANTHEISM (Greek, *pan*, all, and *theos*, god), in philosophy, the doctrine of the identity of God and the material universe. The doctrine stands midway between atheism and dogmatic theism. There are only three ways in which the philosopher can deal with the idea of the existence of God, that is, of a being who is the cause or original sum of all being. He may deny his existence altogether, or may infer psychologically that there is a God, and proceed to the inference that he is the first cause of all things, but leave unexplained the nature of the relation between God as cause and other existences as effects. Finally, he may proceed to reason back from the effect to the cause, and show a necessary connection between them. The last process is the source and explanation of pantheism. The origin of the idea of a God with the theist and the pantheist is the same. It is by reasoning upon ourselves and the surrounding objects of which we are cognizant that we come to infer the existence of some Superior Being upon whom they all depend, from whom they proceed or in whom they subsist. Pantheism assumed the identity of cause and effect, and the consequent adequacy of each effect, rightly interpreted, to indicate its cause. Matter, not less than mind, is with it the necessary emanation of the deity. The unity of the universe is a unity which embraces all existing variety, as proceeding from it in a way necessarily explicable by the result. Hence each existing thing contains all the explanation of its own existence which it is capable of receiving.

The earliest school of Greek philosophy, the

Ionian, in as far as it admitted any theism, was essentially pantheistic; and to the same school of pantheism belong Epicurus and Lucretius in ancient, and Giordano Bruno in modern times. The atomic theory, or the origination of all things in conscious atoms, is the culminating theory of this school. The Sankhya of Kapila, one of the most celebrated Indian systems of philosophy, in which probably developed the Buddhist religion, was the chief representative of pantheistic tendencies in the East. Kapila enumerates 25 first principles of things: of which the first (*mulaprakriti*) is matter; the second (*buddhi*), intelligence; the third (*ahan-kara*), self-consciousness. Speusippus, the sister's son and successor in the Academy of Plato, might be called an ultra-pantheist. He taught, what may possibly be considered the true logical culmination of the doctrine, that the Divine or Best is first indeed in rank, but is chronologically the last product of development. He defined happiness as the habit of conformity to nature. The soul, according to him, was a higher union of the arithmetical and the geometrical, or extension harmoniously shaped by number. The Stoics, differing widely from the school of Epicurus, may also be numbered among the adherents of pantheism. Their doctrine was that whatever is real is material. The universe as a whole possesses consciousness, and this consciousness is deity. The world undergoes a constant evolution, the elements of water, earth and air being evolved out of fire, which again absorbs them, and the process continues in an eternal cycle. The human soul and the deity, which are one in nature, act and react on each other. Intelligence, whether in man or the deity, they considered as consisting chiefly in force. Perhaps there is nothing which seems more opposed to pantheism than the mysticism of the Alexandrian school, and particularly of Plotinus, which makes of God so pure an abstraction that even thought, without being separated from individuality, cannot attain to it. Yet from the bosom of this school a prolific source of pantheism has arisen. Dionysius, the pseudo-Aeropagite, a Christian philosopher of the Neoplatonic school, introduced it among his speculations, in which the particular is derived by a series of gradations, as genus and species, from the universal. John Scotus Erigena, the founder of the scholastic philosophy of the Middle Ages, gave this speculation a realistic turn, making God the essence of the world, and the universal, the genus, the species and the individual so many particular developments which actually succeed each other. Eckhart, a German philosopher of the beginning of the 14th century, also a disciple of Dionysius, and often regarded as the father of German philosophy, taught some views which were developed in a pantheistic direction by some of his followers. Eckhart held that the works of creation were eternally in God in idea or conception; this was developed into a pantheistic doctrine of the eternal existence of ideas or types of all things. Giordano Bruno, like Epicurus and Lucretius, taught that monads are the elements of all existing things. God is the imminent cause of the universe. Power, wisdom and love are his attributes; but he is the monad of monads, the minimum because all things are external to him; the maximum

because all things are in him. He produces the worlds freely, but by an inner necessity of his nature. The worlds are nature realized; God is nature working. Stars are moved by the souls that reside in them. God is in all things, as being in things that exist, or beauty in objects that are beautiful.

No modern pantheist has acquired a greater renown than Spinoza, probably because none has developed his doctrines into a system so comprehensive or with a logic so rigorous. A disciple of Descartes, he founds upon that master's definition of cause a system in which he develops the relation of God to the universe in a series of propositions, graduated like a succession of consequential demonstrations in mathematics. According to Spinoza the essence of God is existence, and he has two fundamental attributes, extension and thought. All things which exist are modes of God's attributes. Their existence is necessary, and all changes which take place in them, whether affecting intelligent or non-intelligent beings, are necessary. God alone is free, and he is free because he acts by an inner necessity and is not controlled by any other being. It may be added that Spinoza combats the apparent inference from his doctrine, that the sum of things which exist is God. Things are diverse, complex and limited, while God is one, simple and infinite. They are not God, but only the necessary modes of his attributes. Among modern pantheists a place is also due to Leibnitz. According to him all souls are monads, or atoms containing active powers consisting in ideas. God is the primitive monad; all other monads are its fulgurations. Bodies, as plants and minerals, are aggregations of sleeping monads with unconscious ideas. The relations of the monads are purely mechanical, and their co-operation is determined by the theory of pre-established harmony. The French philosopher Diderot recognized God in natural law, truth, beauty and goodness; for Leibnitz's monads he put atoms and gave them sense in place of ideas, which became thought in organized beings. Finally, the modern doctrine of evolution, when it assumes a transcendental form and carries speculation as to the origin of things beyond the range of inferences founded on the observation of nature, is necessarily pantheistic. See ATHEISM; DEISM; THEISM; THEOSOPHY.

PANTHEON, anciently a name applied to a temple or shrine dedicated to the gods. The most historical pantheon is that erected in Rome by Hadrian 117-138 A.D. and dedicated by him as a temple to all the gods. For 13 centuries it served as a Christian church, having been dedicated by Boniface IV about the year 607. It is 188 feet in circumference and is covered by a dome 142 feet in span. The entire height is 141 feet. Raphael and Victor Emmanuel II are buried in the Pantheon. Another noted structure bearing this name is the Pantheon of Paris (church of Saint Genevieve), for a description of which see PARIS.

PANTHER, a large cat, in North America usually a cougar; in South America a jaguar; in India or Africa a leopard.

PANTHER-CAT, a name locally given to several spotted wildcats; most often, probably, to the ocelot (q.v.).

PANTIN, pǎn'tǎn', France, town in the department of the Seine, just without the fortifications of Paris. It has a number of thriving industrial establishments, including sugar mills and refineries, railroad car shops, boiler works, chemical and perfume works, glass works, oil-cloth mills, etc. Pop. 36,359.

PANTOGRAPH, an instrument by the aid of which maps, plans and designs may be copied mechanically, either on the scale on which they are drawn or on an enlarged or reduced scale. It is made in a variety of forms.

PANTOLAMBDA, a primitive ungulate fossil mammal, occurring in North America and Europe but confined to the Eocene period. It developed the full series of 44 teeth with the upper molars of the selenodont type. The feet were stocky and postlike, closely resembling those of the elephant. The *Pantolambdæ* never reached the length of body of its cognate type among the Amblypoda, the *Coryphodon*, which in some cases was as great as 10 feet. Consult Osborn, H. F., 'Evolution of the Amblypoda' (in *Bulletin of the American Museum of Natural History*, Vol. X, p. 169, New York).

PANTOMIME, the name given by the Romans to an actor in a dramatic performance consisting of dance and gesture. This sort of representation appears to have been indigenous to Italy. The modern Christmas pantomime in Great Britain is a spectacular play of a burlesque character, founded on some popular fable, and interspersed with singing and dancing, followed by a harlequinade, the chief characters in which are the harlequin, pantaloons, columbine and clown.

PANTOPODA, or **PYCNOGONIDA**, a group of marine spider-like, but hard-shelled arthropods, which is classified near the horseshoe crabs (*Limulus*). The body (*cephalothorax*) is so small and the limbs are so large that the animal, which may span two or three inches in large species, seems all legs, and a popular name along the New England coast is "no-body crab." There are four pairs of equally large many-jointed walking legs, in advance of which are two pairs modified into chelate mouth-organs, and a third pair upon which, in the breeding season, the male carries the eggs cemented to these appendages. The abdomen is represented by only a small tail-like part posterior to the legs. A metamorphosis occurs in most species, and the larva looks something like a nauplius, but is not equivalent to it. These curious creatures live from the shore-line to deep water.

PANUCO, pǎ'noo-kō, (1) river of Mexico, rising in the plateau north of the City of Mexico and flowing generally northeast. It forms part of the boundary of Tamaulipas and Vera Cruz and receives the waters of several smaller streams before emptying into the Gulf of Mexico near the city of Tampico (q.v.). Its bar has been removed by elaborate engineering works and the river mouth is now a fair port. (2) A district about this river, so called by Cortéz and his followers. It was partially conquered by Cortéz in 1522, but in 1526 was granted to de Guzman, who was independent of Cortéz.

PANYASIS, Greek epic poet of the 5th century B.C., ranked one of the five great epic poets of Greece for his poems on Heracles and on the Ionic migration. He was born in Halicarnassus, and is thought to have been the uncle of Herodotus. His few fragments are edited by Kinkel (1877); the most important are on wine, its use and abuse.

PAOAY, pā-ō-ī', Philippines, pueblo or town, province of Ilocos Norte, Luzon, three miles inland from the western coast, on a small lake; 12 miles south of Laoag. It is on the main highway. Pop. 12,743.

PAOLA, pā'ō-lā, Kan., city, county-seat of Miami County, on the Missouri Pacific, the Missouri, Kansas and Texas and the Saint Louis and San Francisco railroads, about 40 miles south by west of Kansas City. It was settled in 1855 and in 1869 was chartered as a city. It is in a fertile agricultural country and in a natural gas belt. Coal deposits are in the vicinity; cultivating grain and stock-raising are prominent industries in this section. The trade is chiefly in wheat, corn, livestock and coal. It is the seat of the Ursuline Academy, and has public and parish schools and a free public library which contains about 6,000 volumes. The city owns the water-supply system. Pop. 3,207.

PAOLI, pā'ō-lē, **Pasquale de**, Corsican patriot: b. Morosaglia, Corsica, 26 April 1725; d. near London, England, 5 Feb. 1807. He was educated at the Jesuits' College at Naples, and in 1755 was appointed captain-general by his countrymen, then struggling for their independence against Genoa. By his energetic efforts the government and military resources of the island were reformed, and he maintained a protracted and generally successful struggle with the Genoese. The latter, however, first made an agreement with France to garrison the places held by them in Corsica, and finally, in 1768, sold the island to France. After a brief struggle Paoli was obliged to yield, and fled to England. Here he remained 20 years, till the Revolution of 1789, when he was recalled by the National Assembly and made lieutenant-general of Corsica. Dissatisfaction with the extreme measures of the revolutionists in France soon led him to throw himself into the arms of England; in 1793 a British army was landed in Corsica, and through his influence the crown was offered to George III, in 1794. Paoli, however, did not obtain the government of the island and withdrew to England and was pensioned by the British government. His remains were removed to Corsica in 1889. Consult biographies by Arraghi (1843) and Bartoli (new ed., 1891).

PAOLO AND FRANCESCA, a poetic drama in four acts, by Stephen Phillips, based on the famous passage in Dante's 'Divine Comedy' (Il Purgatorio, Canto V). Paolo has been sent to fetch home Francesca, the bride of his stern warrior brother, Giovanni, tyrant of Rimini. Absorbed in his military enterprises, Giovanni commends Paolo and Francesca to each other's society with perfect faith in their loyalty to him. They, on their part, with no thought nor wish other than their duty to brother and husband, are overpowered by the irresistible call of youth to youth.

7 "Unwillingly he comes a wooing; she
Unwillingly is wooed: yet shall they woo."

Giovanni, discovering their guilt, is driven both by passion and his social code to destroy them, though he destroys thereby all that he loves in the world. 'Paolo and Francesca' belongs to the best of Stephen Phillips' work and when first published (1899) it was hailed as ushering in a new era in the poetic drama of the English-speaking world. It contains many passages of great beauty and has a singular pictorial quality; but as drama it halts and loiters by the way instead of moving swiftly and surely to its tragic end. The prose interludes in the tavern and in the opening scene of Act III, are as foreign to the tale as they are to the versification, while Paolo's soliloquy and the meeting of Paolo and Giovanni at the chemist's shop are awkward and thoroughly old-fashioned expedients. The only touch of novelty in dramatic treatment is in making the thwarted maternal instincts of Giovanni's housekeeper do service, in place of the customary villain, in arousing his suspicions. As a play, 'Paolo and Francesca' has neither the passionate sweep and dramatic intensity of d'Annunzio's 'Francesca da Rimini' nor the breathless atmosphere of mystery and impending doom in which Maeterlinck has enveloped an almost identical theme in 'Pelleas and Melisande.' It is essentially lyric in character in spite of its tragedy. This quality is exquisitely expressed in Giovanni's closing lines, as he looks upon the dead lovers:

. . . "She takes away my breath.
I did not know the dead could have such hair.
Hide them. They look like children fast asleep."

'Paolo and Francesca' was first performed in London in 1902 and in New York in 1906.

PAPACY, the doctrine of the Roman Catholic Church relative to the authority of the Pope, that is, the Papacy, was officially promulgated by the Council of the Vatican in 1870. The primacy, it teaches, over the entire Church was conferred by Christ on Peter; and this primacy was one, not of mere dignity, but of full and supreme jurisdiction. This supreme authority is exercised by the bishops of Rome "for none can doubt; and it is known to all ages, that the holy and blessed Peter, the prince and chief of the Apostles, the pillar of the faith, and foundation of the Roman Catholic Church, received the keys of the kingdom from our Lord Jesus Christ, the savior and redeemer of mankind, and lives, presides, and judges, to this day and always, in his successors, the bishops of the Holy See of Rome, which was founded by him, and consecrated by his blood." Hence, the council continues, the Roman See possesses a superiority of ordinary power over all other sees; and this power of jurisdiction is immediate, so that to it all bishops, pastors and the laity, both individually and collectively, are bound to submit, not only in matters which belong to faith and morals, but also in those that appertain to the discipline and government of the Church. In virtue of this supreme power, the Roman Pontiff claims the right of free communication with the bishops of the entire world and their flocks. To him as to the supreme tribunal, in all causes, the decision of which belongs to the Church, recourse may be had and from his judgment there is no appeal. The as-

sertion that it is lawful to appeal from him to an ecumenical council is condemned as false. The infallibility of the Pope in doctrinal matters is thus defined:

"We teach and define that it is a dogma divinely revealed, that the Roman Pontiff, when he speaks *ex cathedra*, that is: when, in discharge of the office of pastor and doctor of all Christians, by virtue of his supreme Apostolic authority, he defines a doctrine regarding faith or morals to be held by the Universal Church, by the divine assistance promised to him in blessed Peter, is possessed of that infallibility with which the divine Redeemer willed that his Church should be endowed for defining doctrine regarding faith or morals; and that, therefore, such definitions of the Roman Pontiff are irreformable of themselves and not from the consent of the Church."

It is not now maintained that the full significance of the Petrine primacy was manifest from the first in the life of Christianity; but rather, that there was, from the beginning, to borrow Cardinal Newman's words, a certain element at work, or in existence, divinely sanctioned, which for certain reasons did not at once show itself on the surface of ecclesiastical affairs, but gradually with the expansion of the Church, and in response to the needs of the times, developed into full vitality. What was the date of Peter's first appearance in Rome is not clear. Critics of all shades agree that Peter was in Rome in 64, when the Christian community was already established and that he suffered martyrdom there during the reign of Nero. Roman Catholic writers lay stress on the testimony of Eusebius and Jerome who refer to tradition in proof that Peter had been in Rome before 64. The earliest picture that we have of the Christian Church presents the community rather than the bishop. The writings of Clement seem to point out the community as the seat of authority: the letter ascribed to Ignatius of Antioch addresses the Church of the Romans; and Pope Soter in 170 speaks as in the name of the community, rather than in his own. But the march of events rapidly brought about two results, the domination of the bishops over the various churches and an active pre-eminence of Rome over the others. After the fall of Jerusalem, Rome, the political mistress of the world, soon became the centre of Christianity; other bishops began to consult Rome on ecclesiastical matters. Polycarp, the disciple of Saint John, had recourse to Anicetus on the vexed question of the Paschal celebration, though, it is true, he declined to abandon the Asiatic for the Roman custom. In 194 Pope Victor took steps to enforce the Roman discipline by the excommunication of recalcitrants. From the middle of the 2d century, the Gnostic and Montanist controversies served to bring the Roman authority into prominence. To the Church of Peter as to the witness of traditional doctrine disputes were referred. The imperial government, too, recognized the precedence of the Roman bishops over all others; the Emperor Aurelian, in 274, decided that the Christian Church property in Antioch should be dealt with as the bishops of Rome and Italy thought fit. In 256 Cyprian of Carthage speaks of Rome as the seat of the primacy. During the 4th and 5th centuries the Roman primacy looms larger and larger. The facts which indicate this rising domination are admitted by Protestant historians as well as by Roman Catholics. Newman cites as suffi-

cient evidence for the 4th century the following passage from the Anglican Bishop Barrow:

"The Pope's power was much amplified by the impurity of persons condemned or extruded from their places, whether upon just accounts or wrongfully, and by faction; for they, finding no other more hopeful place of refuge and redress, did often apply to him; for what will not men do, whither will not they go in straits? Thus did Marcion go to Rome and sue for admission to communion there. So Fortunatus and Felicissimus in Saint Cyprian, being condemned in Africa, did fly to Rome for shelter; of which absurdity Saint Cyprian doth much complain. So likewise Martianus and Basilides in Saint Cyprian, being ousted of their sees for having lapsed from the Christian profession did fly to Stephen for succor, to be restored. So Maximus the Cynic went to Rome to get a confirmation of his election at Constantinople. So Marcellus, being rejected for heterodoxy, went thither to get attestation of his orthodoxy, of which Saint Basil complaineth."

Many other instances of Papal interference for the restoration of bishops or the appointment of new bishops and the designation of others to act as vicars of the Pontiff are also cited from Barrow. While the apologists of the Papacy and its antagonists agree upon the facts, they differ in their respective interpretations of them. What one side considers as evidence of the universal recognition accorded to the primacy, the other treats as evidence of an ever-widening policy of "papal aggression." The Protestant theologians, besides, throw emphasis upon a few notable cases of remonstrance addressed by bishops of other sees to the actions of Roman pontiffs, and see in Cyprian's acknowledgment of the primacy nothing more than an acknowledgment of pre-eminent dignity. The definitive recognition of the spiritual primacy is found in the great Council of Chalcedon, presided over by the legates of Leo I (451). The 630 bishops there assembled accepted as authoritative the profession of faith imposed by the Pope; they are reported to have unanimously exclaimed: "What Leo believes we all believe; anathema to him who believes anything else. Peter has spoken by the mouth of Leo." The removal of the empire to Constantinople was fraught with far-reaching results on the Roman world in temporal as well as in spiritual affairs. In the 9th century writers is found a story that, on his withdrawal from Rome, Constantine granted to Pope Silvester, Rome, Italy and the Western Islands. This famous donation of Constantine was treated as authentic by the canonists and jurists of the Middle Ages. "It is," says the latest English Roman Catholic historian of the Papacy,

"a prophecy after the event. Paganism, abandoned, and soon to be persecuted by its Pontifex Maximus, without the conviction that makes martyrs, and long a hollow formality was dying. Christians had the State in their hands. What was more, they showed the fiery zeal, the proselytizing spirit, the exuberance in quarrels among themselves, which are signs of a youth rich in hopes, bent upon shaping its own victorious future. Heathen Rome invited them to subdue it. Public policy required that the centre of administration should be at the heart of the Empire. The balance of power was displaced. Neither Pope Silvester, nor any Pope for centuries, dreamed of disowning the imperial rule; from the Goths in Italy they suffered grievous things as the first subjects of Constantinople. But Rome left to herself was Rome in the hands of the Papacy; fronting the West and the barbarians, Constantine had imitated Alexander, who in setting up his throne in Babylon in 330 B.C.—a curious coincidence—and assuming the tiara, left Europe free to follow its own fortunes. Such was the real donation, not understood at the time by Pope or Emperor, which never lost its force until the northern nations grew into a world as Greek, as cultivated and as haughtily self-conscious as the Greek."

The capture of Rome by Alaric in 410, the subsequent invasions of Italy by Attila the Hun

and Genseric the Vandal, reduced the imperial authority to the shadow of a great name, and the wane of Byzantine influence was accompanied by a corresponding growth of political power in the Papacy in whom the people found their only protection and succor against the barbarians. For a brief interval the genius of Justinian, with the military successes of Belisarius and Nares, brought the popes once more under the sway of Constantinople. With the rise of the Lombard power in Italy the doom of the Western Empire was sealed. By his vain effort to extirpate the use of images in worship the Emperor Leo the Isaurian (726) drove the Roman and Italian populations to transfer their civil allegiance to the Papacy, which, through the wisdom, administrative ability, virtue and apostolic zeal of Pope Gregory the Great (590-604) had become the national centre of Italy. The pontificate of Gregory is a luminous phase in Papal history. It witnessed the rise of the Benedictine Order whose monks established Christianity in England and initiated the work of civilizing Europe. The Anglican Bishop Creighton summarizes the immediate and subsequent results of this mission:

"While dangers were rife at Rome, a band of Roman missionaries carried Christianity to the distant English, and in England was founded a Church which owes its existence to the zeal of the Roman bishop. Success beyond all that he could have hoped for attended Gregory's pious enterprise. The English Church spread and flourished, a dutiful daughter of her mother-church of Rome. England sent forth missionaries in her turn, and before the preaching of Willebrod and Winifred heathenism died away in Friesland, Franconia and Thuringia. Under the new name of Boniface, given him by Pope Gregory II, Winifred, as archbishop of Mainz, organized a German Church, subject to the successor of Saint Peter."

The middle of the 8th century saw the alliance of the Papacy with the Franks. The last of the Merovingians had become a puppet in the hands of Pepin, the mayor of the palace. The nobles offered the crown to Pepin, who consulted Pope Zachary. The Pope replied: "Let him be King in name, who is in fact so," and Pepin was anointed by the deputy of Zachary (751). This fact became a precedent, in the public law of Europe, for the Papal claim of indirect authority over temporal sovereigns.

The grateful Pepin bestowed on Pope Stephen III large territories which he had wrested from the Lombards; and in return he received from him the title of Patrician of Rome, an event that opened the way to the establishment of the empire which with the Papacy was to constitute the unity of Christendom. Pepin's son, Charlemagne, was crowned emperor by Pope Leo III, in Saint Peter's, at Rome, on Christmas Day, 800. When under the descendants of Charles, the short-lived unity of the empire was broken up into separate states the Papacy stood forth in the minds of men as the paramount authority in the political, as it was in the spiritual, world. "The Church," writes Barry,

"instead of breaking up as Charles' monarchy had broken up, into petty and opposed principalities, is centralized in the West. A supreme court of appeal is set up in the sight of mankind, its charter the Bible, its weapons spiritual, but entailing penalties in this world. For deposition, interdict, excommunication, greater or less, carry in their train forfeiture of dignity, good, life, and the Holy See can reckon on sentiments which become the foundation of order, in the State and in the Church."

Pope Nicholas I exercised his supremacy in both realms (858-867). He obliged the Frank-

ish King Lothair II to take back the wife whom he had attempted to divorce. He deposed the powerful archbishops of Cologne and Trèves who had sided with the king, and against the opposition of the Byzantine emperor he condemned Photus, who had intruded himself into the patriarchate of Constantinople. About this time appeared the famous *False Decretals*, which were embodied in the canon law of Europe. This collection of decrees was first presented at the Synod of Quercy in 857, when the Frankish bishops were contending for alleged rights and privileges against their metropolitans. It purported to be the work of Isidore of Seville. There had been a genuine collection edited by this author. But the present volume contained, besides some authentic decrees, the Donation of Constantine, several forged decrees and acts of spurious synods. The author is generally supposed to have been a Western Frank. His object was to set up an entire immunity for the clergy and to present the Pope as not only supreme ruler in ecclesiastical affairs, but also the supreme appellant judge in even secular causes. The bishops were exalted and protected against their immediate superiors, but, on the other hand, they were reduced to something like a condition of feudal vassalage to the Pope. In short, the rights of synods, metropolitans, clergy and laity were swept away. The general conception embodied in these decretals was woven into the law of Christendom during the Middle Ages.

The middle of the 9th century was characterized by a rapidly spreading confusion and civil and moral disorder throughout Europe. The most signal exercise of Papal authority was the conferring of the empire on Charles the Bald by John VIII. The Saracens, the Normans and the Slavs were carrying their victorious arms into southern, western and central Europe. Italy was the scene of incessant strife. The popes were unable to resist the attacks and oppression of Italian nobles and Norman chiefs. As the power of the great vassals of the crown increased, the disintegration of the empire continued its course; and something akin to anarchy prevailed. The condition of the Papacy reflected the evils of the times. Disorders in elections, corruption in administration, license in morals, mark the Papal history of this period. In the House of Theophylact the Papacy almost assumed the character of an hereditary monarchy. The lowest depths of degradation were reached when Alberic of Tusculum made his son, a vicious boy of 12, Pope under the title of Benedict IX. After holding the position for some time, Benedict sold it to Gregory VI, in order to get married. There was another claimant known as Silvester III. Benedict endeavored to resume the sovereignty. Monks like Peter Damian and Hildebrand deplored and endeavored to mitigate the universal disorder. The empire had passed to the German House of Otho. Henry III endeavored to put an end to the degradation by deposing the three unworthy claimants and appointing a German to the throne of Peter (1046). Notwithstanding the powerful influence and resolute endeavor of the monk Hildebrand the reign of misrule continued till he himself became Pope, under the name of Gregory VII. He set about the reformation not only of Rome but of

the entire Church, recalled the clergy to the vows of their profession, took severe measures against the universal vice of simony and asserted the Papal claims against the secular powers. A long struggle of much vicissitude against the imperial power ended by the humiliating capitulation of Henry IV at Canossa (1076). The influence of the universities, especially those of Paris and Bologna, contributed, by their teachings in law, philosophy and theology, to establish the majesty of the Papacy as the supreme authority in the opulence of power ascribed to it by the Decretals of Gratian. The Crusades gave exercise to the popes' claim of suzerainty over all the temporal rulers of Europe. The Papal dominions were enriched in 1115 by the Countess Matilda's bequest of her extensive possessions. A long quarrel with the emperors concerning the right of ecclesiastical investitures ended in a further triumph of the Church over secular feudalism; the Concordat of Worms, however, conceded to the emperors the right to send deputies to the election of German bishops and of investing them with the regalia before episcopal consecration. This was the first of the concordats between the Papacy and the states which indicate the growing restlessness of the civil powers. About the middle of the century a more serious conflict arose between the popes and the Hohenstaufen emperor, Frederick Barbarossa, who undertook to restore the imperial authority over the Italian states and establish his sway over both clergy and laity. The genius of Alexander III triumphed; and Frederick, like Henry IV, was obliged to submit (1177). Everywhere, however, the young nations of Europe, developing their national codes, and becoming conscious of their strength, were, at the end of the 12th and the beginning of the 13th century, showing signs of restiveness under the dominion of the Church. In England Henry II began his struggle with Thomas of Canterbury. The constitutions of Clarendon claimed almost as much for the civil power as was demanded afterward by Henry VIII. Fearful that Henry might join hands with Frederick, the Pope temporized. But when the death of Becket stirred up the people against the king, the Plantagenet was compelled to sue for peace no less humbly than the Hohenstaufen. In the reign of Innocent III the power of the Papacy reached its zenith. A man of lofty character, indomitable courage and great political insight, he dictated to the rulers of France, Germany and England. For a short time the arms of Venice brought Constantinople under his spiritual sway. By the help of the Crusaders he crushed, with great severity, in northern Italy and southern France the sects which disputed the authority of the Church. The new orders of Saint Francis and Saint Dominic, powerful in their primitive fervor and virtue, renewed the religious spirit in every country and awakened in the consciences of the people the old devotion to the Church and its sovereign ruler. Innocent, more conspicuously than any of his successors, acted as an independent Italian prince, expelled the imperial officers from the domains which Matilda had given to Rome; and under him the states of the Church became an autonomous kingdom. Thenceforward we see the Pope strengthened and burdened with a temporal sovereignty; and

more than once, in subsequent history, the necessity of defending it becomes a serious embarrassment to him in the discharge of his office of Spiritual Father of Christendom. Though Innocent was successful in asserting his feudal authority, the resistance offered to him indicated that the mediæval awe of the Papacy was rapidly passing away. Some of his acts rankled in the hearts of the peoples and bore fruit in later times. To trace the effect of his intervention in the affairs of England, by absolving the nation from its allegiance to King John, and by annulling, as vile and base, Magna Charta, the foundation of English liberty, would carry us to the days when, in a darker hour, another Pope, by a similar act of absolution, and of deposition of the sovereign rendered definitive the breach between England and the Holy See.

Another and a final struggle between the Papacy and the German emperors opened with the reign of Frederick II. Frederick attempted to reduce the popes to a state of dependence on the imperial authority. Gregory IX and Innocent IV vigorously resisted and after a long and demoralizing struggle overcame him; and the popes did not rest easy till the last of the Hohenstaufens, a mere youth, was beheaded (1286). With Frederick perished the empire which, under Charlemagne, had arisen as the temporal element that in union with the spiritual Papacy had formed the theocracy of the Middle Ages. Though the feudal Papacy had conquered the empire it was not destined long to survive it.

The French influence introduced into Italy soon dominated the elections and popes were chosen with a view, not to the interests of the Church, but to those of the French king. In the reign of Boniface VIII (1294-1303) the Papacy and the secular power closed in a death struggle from which the state rose victorious in the person of Philip the Fair of France. Already, by the instrument known as the Pragmatic Sanction, Louis IX had claimed for the Gallican Church freedom of patrons from Papal interference, freedom of election to chapters and immunity from Papal taxation without the consent of the Crown and the Church. The chief sources of revenue exacted by the popes about this period were the fruits of the first year taken from vacant livings and from money left by previous incumbents; the annates taken from benefices conferred by the Pope; taxes for the confirmations of bishops and for pallium fees; taxes for dispensations; Peter's pence; tributes from secular princes and religious institutions placing themselves under the protection of the Pope; the feudal tax from the vassals of the Pope. The popes widely exercised the right of presenting to benefices; granting "expectances" to benefices; nominating to certain reserved prebends and bestowing others in *commendam*. When Philip imprisoned a Papal legate the great struggle was on. In reply, Boniface issued the Bull *Clericis Laicos*, declaring that the civil authority possessed no jurisdiction over ecclesiastics. He summoned the leaders of the French clergy to Rome. Philip and his lawyers answered that the Pope had no authority on temporals and that his collations to benefices were null and void. Another letter from Boniface told Philip, "Let no one persuade

you that you are not subject to the chief of the Heavenly hierarchy." Philip burned the letter. Then came the Bull *Unam Sanctam*, declaring that every human creature is subject to the Roman Pontiff. The end came when, after being maltreated at Anagni by the minions of Philip, he died, in prison, abandoned by all, 11 Oct. 1303. With him the mediæval Papacy passed away. For centuries afterward canonists and theologians continued to recite the right of the Pontiff to take away and to give crowns; but the world took no notice of the claim. Henceforward the Pope is for history the spiritual ruler of the Catholic Church and the sovereign of a small and gradually diminishing Italian state which, in 1870, was, against the protest of the Pope, absorbed in the kingdom of Italy. Even the most hostile historians of the Papacy concede it as much merit as is given it in the temperate words of Barry:

While it leaned on the people its triumph was assured; when it submitted to the feudal system, it courted disaster. Then the royal authority took away its rod of dominion; the king became Pope; the Pontifex Maximus retired into the holy place before him. Crimes, abuses, usurpation, scandals, and a secret change about religion in the thoughts of men account for this latter-day revolution. But it is difficult to imagine how Europe could have survived from the fall of the empire to modern times, had there been no central, supreme, and acknowledged power like the Papacy, guardian, at once, of faith, learning, and civilization. That it always rose to the height of that great enterprise will not be maintained by the historian, but its benefits outnumbered by far its abuses; and the glory is not dim which hangs round its memory, when we call to mind that it consecrated the beginnings of a peaceful Christian Europe, and watched beside the springs of art, science, industry, order and freedom.

By the transfer of the Papal Court to Avignon the Papacy passed under French influence, which along with the relaxation and disorders that attended its residence there seriously impaired its prestige (1305-77). Its return to Rome was the signal for the great schism of the West, in which Pope and anti-Pope contended for the allegiance of a distracted Christendom till the Council of Constance restored order by the election of Martin V in 1417. With the passing of the temporal Papacy, the spiritual supremacy of the Pope in the Roman Catholic world became more emphasized. The extent of Papal authority and prerogative in the Church was explicitly defined by the Vatican Council. A decree of the Council of Constance, which assembled in 1414, in order to terminate the Western schism, had declared the Pope to be inferior to a general council. The French clergy, in 1682, subscribed to a set of formulæ, known as the Gallican Articles, which affirmed that the consiliar authority is above the Pope, and, consequently, that *ex-cathedra* Papal utterances are not irreversible until confirmed by a General Council. After a prolonged debate, during which it was manifested that the decrees of Constance were intended to apply only to the occasion which gave them birth, and that the Gallican doctrine had been repudiated by the Church, the Vatican Council settled the question by the definition given above.

The long endurance of the Papacy, during ages which have seen the disappearance of every other European institution that was in existence when the Papacy arose, and of so many others that were, but are no longer, while it stands, is a fact which has arrested the attention of every serious historian. It is appealed to by the Catholic apologist as evidence that the

Church is not a mere human institution. To arrive at an impartial estimate of the Papacy, the historical student needs carefully to distinguish its spiritual element—essential and abiding—from its secular adjuncts, which wax large and wane with the vicissitudes of time. (See CATHOLIC CHURCH; CHURCH STATES; POPE; TEMPORAL POWER; related references and biographies of different popes). For a classical explanation and defense of Papal supremacy consult Cardinal Newman's 'Anglican Difficulties' (Vol. II, 1898); or in 'The Chair of Peter,' by John Nicholas Murphy (1883); consult also Barry, W. F., 'The Papal Monarchy from Saint Gregory the Great to Boniface VIII' (New York 1902); Creighton, M., 'History of the Papacy' (6 vols., London 1902-04); Greenwood, A. D., 'The Empire and the Papacy in the Middle Ages' (London 1902); Milman, H. H., 'History of Latin Christianity' (4 vols., New York 1903); Nielson, F. K., 'History of the Papacy in the Nineteenth Century' 2 (vols., New York 1906); Ranke, L. V., 'History of the Popes During the Last Four Centuries' (3 vols., London 1908-12).

Of the Catholic University, Washington, D. C.

PAPAIN, a digestive ferment isolated from the juice of the half-ripe fruit of the tropical papaw tree (*Carica papaya*). The juice is used in the West Indies to make meat tender. Papain is a grayish powder, soluble in water and glycerine, insoluble in alcohol, ether and chloroform. It digests fibrin and albumen more readily than pepsin, and in alkaline, neutral and acid solutions. It is used in some forms of dyspepsia, as a solvent of false membranes in croup and diphtheria, gastritis, infantile diarrhoea and for the removal of warts. As a solvent it is used in solution (5.15 per cent) in equal parts of water and glycerine. It has been recommended as a galactagogue and an anthelmintic. It is sold in powdered and tablet form and also as a glycerole.

PAPAJO (pä'pä-hō) **INDIANS**, an American tribe of the Piman family originally occupying a large part of Arizona. Branches of the tribe extended into Mexico. They were early christianized by the Jesuits and Franciscans and are nearly all devout Roman Catholics. They were once recognized as citizens by Mexico, but after the annexation of the Arizona country by the United States, the Papajos lost not only their citizenship but their lands and water rights, and were persecuted by the white settlers. During the early part of the 19th century they were almost constantly at war with the Apaches. They now number about 4,000, live on reservations and are devoted to agriculture.

PAPAL GUARANTEES, Law of, a law passed in 1871 by the Italian legislature with a view to adjusting the disputes between the papal curia and the civil government. It had all the appearance of a liberal, even generous, attempt at conciliation and the establishment of mutual independence. Its principal provisions were as follows: (1) The Pope was secured the standing of a sovereign power with a court, special ambassadors at Rome, separate postal and telegraphic communication with other countries, and an annual salary of 3,225,000 francs from

the national exchequer. (2) The Vatican and Lateran palaces, etc., were settled on Pope Pius IX and his successors. (3) The *placet* or *exequatur* of the king was not to be required as a ratification of acts of papal authority in ecclesiastical matters. Bishops were not obliged to take oath of allegiance to the king. (4) The clergy were granted the right of assembling. (5) While the ecclesiastical courts were to have the right of deciding cases brought before them without any appeal against their decisions to the civil courts, the aid of such courts in enforcing her decisions was to be denied to the Church. The opinion of the Liberals was that this measure gave a Pope too much independence, and when it was submitted to the Powers England refused her sanction. Finally the Pope decided not to consider the Law of Papal Guarantees but to remain at Rome in his own right, without asking anything of the civil government.

PAPAL VESTMENTS. See COSTUME, ECCLESIASTICAL.

PAPANTLA, pä-pänt'lä, Mexico, town in the state of Vera Cruz, 115 miles northwest of Vera Cruz, on a well-watered plateau. It is in the centre of the vanilla district and has a population of 10,000. About seven miles from the city is a famous teocalli with other ancient ruins, all overgrown with tropical vegetation.

PAPARRHIGOPULOS, pä-rē-göp'oolōs, **Constantine**, Greek historian: b. Constantinople, 1815; d. Athens, 26 April 1891. His father, uncle, brother and other relatives having been beheaded after the Revolution of 1821, he left Turkey and was educated at Odessa under the patronage of the Tsar. In 1851 he became professor of Greek history in Athens. He wrote various monographs in Greek history, and collected in 1858 and 1890, and, in Greek, a 'History of the Greek People' (1860-74), which he abridged and rewrote in French under the title 'Histoire de la civilisation hellénique' (1878). Both these works aim to show the unity and continuity of Greek history, and especially to rehabilitate the inconoclastic emperors and show the importance of their reigns.

PAPAVERACEÆ. See POPPY.

PAPAW, a popular name for several distinct fruits. The papaw of the tropics (*Carica papaya*) is a small palm-like tree of the family *Caricaceæ*. It has usually an unbranched stem, which bears a crest of alternate leaves in the axils of which are borne racemes of small flowers, followed by yellow fruits sometimes a foot long and containing a large quantity of black seeds. The immature fruits are cooked like squashes, and some persons eat the ripe ones raw. In climates free from frost the plants are grown as a home vegetable or fruit.

Other papaws are members of the genus *Asimina* of the family *Annonaceæ*. The best known of these is probably *A. triloba*, a small tree native to the southern United States, but represented as far west as Kansas and as far north as Michigan and New York. The flowers, which are two inches in diameter and appear with the leaves, are at first green but change to purplish-red with yellow centres. The fruits are dark brown, from two to six inches long, and highly aromatic. As a garden fruit this species seems worth attention; selection should

reduce the size of the large stones and modify the flavor. A few improved varieties have been disseminated. Apart from its fruit the tree is of considerable value for ornamental purposes.

PAPE, päp, **Eric**, American painter: b. San Francisco, 17 Oct. 1870. He was educated in Paris under Boulanger, Lefebvre, Constant, Doucet, Blanc and Delance, and at the École des Beaux-Arts under Gérôme and Laurens. He has lived in England, France, Germany, Mexico and Egypt. In 1897 he was instructor in the Cowles Art School of Boston and in 1898 founded the Eric Pape School of Art of which he remained conductor until 1913. Mr. Pape has exhibited 22 pictures at the Paris Salon, the Chicago Exposition and the Munich Kunst Ausstellung 1897; 120 paintings at the Omaha Exposition 1899, Paris 1900, 100 paintings at Buffalo 1901, and Saint Louis 1904. He designed a large monument to commemorate the founding of the Massachusetts Bay Colony and was master of the pageant at Gloucester in 1908. Mr. Pape planned and produced the Woman's Titanic Memorial performance in Boston, and directed the Italian Festa performance in Massachusetts in 1915. He has painted many portraits, also made a series of portrait-drawings for 'Ellen Terry's Memoirs' and has illustrated many important works. He has also attempted landscapes, in which field his best efforts are 'Early Morning, Annisquam'; 'A Breezy Morning'; and 'The Dying Day.'

PAPEITA, pä-pä-ē'tē, or **PAPEETE**, Society Islands, capital of the French islands of Polynesia, on the northeastern coast of the island of Tahiti. It has a good harbor, is the commercial centre of the neighboring islands and has a large export trade; it is also the most important French naval station in the Pacific. It contains a cathedral, a courthouse and other French government buildings. Pop. 3,617.

PAPELINE. See POPLIN.

PAPER (Fr. *papier*; Lat. *papyrus*; Gr. *πάπυρος*), a thin fabric or web composed of vegetable fibres felted together in sheets.

The word paper is derived from papyrus, probably the Egyptian name (with a Greek termination) of a sedge or bulrush of the Nile and marshes of Egypt. The plant was used by the Egyptians to make thin sheets primarily for writing upon, though some were used for wrapping. They stripped the rind from the long stems, exposing the pith which was then cut into thin strips. These were laid out flat side by side, forming a layer upon which other strips were laid at right angles to the first. The two layers were then compressed so as to adhere to each other. Sometimes, perhaps generally, three layers were superposed. The article thus formed was called papyrus.

Classification.—The commercial classification of paper is based primarily upon the different uses to which it is to be put. Logically the different kinds of paper fall into two groups: (1) paper for recording and (2) paper for mechanical or practical purposes. The first group may be subdivided into (a) "writing" paper, this being on the whole the best in quality is accordingly known as "fine" paper, and (b) "printing" papers, again subdivided into "book" and "news." The second group includes many varieties, the most important being

"wrapping," but this, too, has many subdivisions. The classification of paper adopted by the United States Census Bureau follows pretty closely this logical idea and is as follows: (1) "news," in "rolls" and "sheets," (2) "book," including "cover," "plate," "lithograph," "map," "wood cut," "cardboard," "bristol board," etc., (3) "fine," including "writing," "ledger," etc., (4) "wrapping," including "manila" (made from rope or directly from jute, hemp and other strong fibres), (5) "straw" (at one time used for printing, but now relegated principally to the wrapping board classes), (6) "bogus manilas" (so called from their being imitations of genuine manilas, although composed of wood fibres), (7) "boards," including "binder boards" (used for binding books), "pulp boards," "straw boards," "news boards" (made from old newspapers). "Boards" in general are used for making paper boxes and for many other purposes; finally (8) "miscellaneous," including "issues," "blotting," "building," "roofing," "carpet lining," "hanging" (wall), etc.

According to the special census of manufactures taken for 1914 the paper mills of the United States in that year made upward of 250 distinct kinds of paper. Although the largest relative values were in fine papers, the larger tonnage by far was that of printing paper. The following figures of output quoted from that census afford a basis for accurate comparisons: Printing paper, 1,973,603 tons; writing paper, 195,351 tons; other fine papers, 52,377 tons; heavy wrapping paper, 98,780 tons; light wrapping papers, 399,593 tons; building and roofing papers, 243,908 tons; tissue papers, 115,401 tons; blotting paper, 14,157 tons; paper boards—pulp board, strawboard, binders' board, trunk and press boards; leather board, trunk and press boards; leather board, etc.—1,208,795 tons.

Materials.—The foundation or basis of all paper is cellulose. All vegetable growths consist of (1) fibres mainly composed of cellulose and (2) various cellular and intercellular matters such as resins, etc. Paper is made of the fibres with as little as possible of the intercellular matter adhering to them.

Chemically, cellulose (q.v.) is a carbohydrate, with the approximate formula, $C_6H_{10}O_5$. But the fibres of which paper is ordinarily made are not pure cellulose; three types of cellulose compounds being recognized. These are: (1) nearly pure cellulose, typified by cotton; (2) pecto-cellulose, typified by flax; and (3) ligno-cellulose, typified by jute, and including practically all the pulp-wood fibres. All of the paper fibres in use carry to a greater or less extent a percentage of wax, fat, lignin, mineral salts and traces of other substances, cotton having the least.

Speaking generally, cellulose is resistant to the commoner solvents, and, therefore, may be readily freed from extraneous matters by chemical action. It is, however, subject to certain changes in the conditions prevailing in paper-making processes, resulting in the formation of oxy-cellulose and hydro-cellulose. The former is apt to be produced in the bleaching bath, as a consequence of the absorption of oxygen from the atmosphere, in cases where the bleaching is carried on under exposure to sunlight, or at a temperature unduly high. Its

presence renders the paper in which it is contained brittle and weak, and faulty in taking dye and holding its purity of color. Hydro-cellulose is the result of a combination of the cellulose with water, resulting usually from the action of ferments in the presence of weak acids or alkalis. It is not wholly objectionable in all cases, being intentionally produced in the manufacture of grease-proof paper.

The typical linen fibre is hexagonal, or at least polygonal in cross-section, rarely round, with gently tapering ends. After treatment for paper making these ends are frayed out into a number of threads known as "laminae." A very narrow canal runs the length of the fibre. There are liable to be also minute nodules or bulbs strung along the fibre, but these are commonly crushed in the paper-making processes. Cotton fibre is flat or ribbon-like, with a canal much more pronounced than that of linen. Generally the cotton fibre twists in drying. Esparto fibre has a short smooth and round fibre, usually tapered at the ends, but often blunt. It, too, has a well-marked longitudinal canal. The fibre of straw is shorter and thicker than that of esparto, and not being so flexible exhibits kinks where it has been bent. It has also the peculiarity of the spiral cell, found in the bagasse of the sugar mill and in bamboo. In jute fibre the canal is very irregular, and there are numerous characteristic striations and markings. This fibre, though longer than that of straw and esparto, is much shorter than cotton or linen. Manila fibre is three times as long as jute, and is one of the strongest used in paper making. In this fibre the longitudinal canal is strongly marked. China grass or Ramie fibre is very nearly the same length as that of linen, but flat like cotton and twice as wide. Wood fibres as found in pulp are flat with a number of twists, as in cotton, but very much shorter. Those from coniferous woods are broader than cotton, and those from deciduous woods are narrower. The following table shows the length and breadth in fractions of an inch of the principal fibres used in paper making.

NAME OF FIBRE	Length in inches	Breadth in inches
Cotton.....	1.1811	0.0098
Linen.....	0.9842	0.0078
China Grass or Ramie.....	0.8661	0.0197
Paper Mulberry.....	0.4724	0.0098
Adansonia.....	0.4724	0.0078
Manila.....	0.2756	0.0078
Bamboo.....	0.1575	0.0059
Sugar Cane Bagasse or Megasse.....	0.1181	0.0059
Wood, Coniferous.....	0.1811	0.0118
Jute.....	0.0984	0.0086
Esparto.....	0.0591	0.0047
Straw.....	0.0591	0.0059
Wood, Deciduous.....	0.0394	0.0078

News paper, in countries where suitable woods are plentiful, is generally made from wood pulp. Elsewhere rags, straw, esparto and other materials are used. The cheaper qualities are made of "mechanical" wood pulp; a better quality of "chemical" pulp, either alone or with a percentage of esparto, a combination possessing excellent characteristics. The highest grades of book paper are made from linen and cotton rags, but a very large and increasing

percentage is made from wood pulp, principally chemical pulp, mechanical or ground wood pulp being used only in the cheaper grades, and with, generally, some admixture of cotton and linen fibre from rags. The two principal varieties of chemical pulp, namely, "sulphite" and "soda," are both used extensively in book papers, a mixture of the two being desirable, as the sulphite pulp alone has a tendency to be harsh and semi-transparent. The best quality of "fine" papers are made of linen rags, chemical wood pulp and cotton rags being used for the lower grades. The best Bible paper is made of rag fibres with starch added to give opacity. The Oxford India paper is made under secret formulas, but successful imitations can be had. Featherweight papers are made entirely of esparto, very little sizing being used. Thick plate papers are made by rolling two or more webs of paper together while still wet. Art papers are coated with a mineral surface like China clay in size. Imitation art papers have about 25 per cent of China clay mixed in with the pulp, and this is brought to the surface by the calendaring process. Writing papers of the highest grade are made of linen rag fibre exclusively. Lower grades have an admixture of cotton, and still lower a percentage of esparto or chemical wood fibre. Wrapping papers are made of all kinds of fibres, but in this country rags for this purpose have been practically superseded by cheaper fibres, notably wood pulp, jute, hemp refuse, old rope and twine, clippings and trimmings from higher grade paper stock and old paper. Boards are made of wood pulp, straw, old newspapers and other fibrous waste materials, according to the particular purposes for which they are intended. Tissue papers are made from a variety of fibres ranging from the manila hemp to wood pulp, the better class being of hemp and rag fibre well beaten and without size. Copying paper is very similar, but has a small addition of mineral matter to give it greater bulk. The papers produced in other countries comprise all those enumerated above and many other varieties or "specialties."

From the 1914 census figures for the amount of materials consumed in the United States by the paper mills in that year an authoritative comparison may be made as to the relative production of the various kinds of paper. Pulp wood consumed totaled 4,470,763 cords; of which 1,892,739 cords were spruce, 602,754 cords were hemlock, 328,513 cords were poplar, and 817,057 cords of all other woods including principally balsam fir, southern pine, white pine, white fir, cottonwood, tamarack and gum. The total includes also 768,056 cords of spruce and 61,644 cords of poplar imported—chiefly from Canada. A rather large proportion (not specified) of this pulp wood was ground and made directly into paper by the mills which make both pulp and paper. Other mills which make only paper purchased a total of 1,521,980 tons of pulp—classified as ground pulp, 379,263 tons; soda fibre, 155,635 tons; sulphite fibre, 436,196 tons; sulphate fibre, 16,414 tons; mechanical screenings, 4,806 tons; and chemical screenings, 21,245 tons. Included in the total were 153,463 tons of ground pulp; 5,289 tons of soda pulp; 261,172 tons of sulphate pulp and 88,497 tons of sulphate pulp imported—mostly

from Canada. Rags, which title included cotton and flax waste and sweepings, amounted to 361,667 tons, of which 88,664 tons were imported. Manila rope amounted to 64,256 tons. Jute bagging and waste totaled 56,914 tons, nearly all imported. Old and waste paper supplied 1,509,981 tons of paper stock, used largely in the making of paper boards. Straw consumed amounted to 307,839 tons; and all other paper stock, 97,276 tons, practically all imported grasses and foreign fibres.

Mention has been made of four descriptions of wood pulp—ground, sulphite, soda and sulphate. The distinctions between these classifications follow:

Ground Wood Pulp.—Grinding is confined to woods. Spruce is used chiefly, though other kinds of conifers are used to a limited but increasing extent. Trees upward of 10 or 12 inches in diameter are felled and transported to the pulp mill either (1) in logs or (2) sawed into lengths of usually four or two feet. Sometimes the wood is peeled in the forests but usually it has the bark removed at the mill by a "barker" or "rossing machine." The "blocks" of wood two feet in length are brought into contact with a rapidly revolving vertical disc set with knives at an angle to the surface after the fashion of a plane, which shave off the bark as the block is rotated before them. Imperfections such as knots, gum seams and decayed portions, if left after barking, are removed by placing the blocks under a "splitter" which splits off the imperfect portions, but usually the block is suitable for "grinding" as it comes from the barker. It is then placed in the "grinder." This consists of a sandstone or emery cylinder about four feet in diameter and up to 30 inches breadth of face set upon a shaft directly driven by a water wheel at great speed. The "stone" is enclosed in a steel case with openings or "pockets" at two or three points in the circumference. The wood, being placed in these pockets, is forced by hydraulic pressure "side-on" against the surface of the revolving stone. The object is to disintegrate the wood by a sort of tearing rather than cutting action and upon the condition of the stone, the relative speed and pressure, the quality of the pulp mainly depends. A continuous flow of water on the stone prevents charring of the wood through friction and carries away the fibrous particles as they are rapidly separated from the block. The pulp is known as "hot ground" if a minimum quantity of water is used, and "cold ground" if a large supply of water is run on the stone. Hot ground fibre is longer and drier, and is better adapted to the making of news print paper for use on quick-running presses. Cold ground pulp makes a stronger and more cohesive paper used in book printing on slow presses. The continuous use of from 75 to 100 horse power is required to produce a ton of pulp in 24 hours. Sometimes as much as 500 horse power is applied to one stone. The pulp-laden streams of water from the different grinders are then converged and directed upon a series of vibrating "screens" which strain therefrom the coarse particles. In some mills the pulp is "refined" by passing through a grinding mill of two horizontal stones, similar to a flouring mill. The flowing pulp stream passes downward through the

centre of the upper stone, and the "refined" pulp is gathered at the perimeter. If the pulp is to be used at once for making paper in the same establishment, it either goes to the "reducers" which withdraw a large quantity of the water, thereby increasing the consistency of the liquid to a pulp mass, which is then stored in tanks; or, if it is to be transported or stored for future use, it passes from the screens in the same diluted condition to the "presses." The press consists of a revolving drum covered with a very fine wire mesh which permits the water to be drawn through and discharged while the pulp fibres are deposited on its surface. The thin film of pulp being allowed to build up layer on layer is removed as fast as it reaches a suitable thickness for handling. The sheets of pulp thus formed, containing water and pulp in about equal proportions, are folded up into "laps" averaging 25 pounds in weight each, go into a hydraulic press to have the surplus water removed, and are then in convenient shape for handling and transporting. This form is known as "mechanical" pulp. In the market it is known as "wet" or "dry"; the former containing 50 per cent of water, the latter about 7 per cent — having been air-dried before baling.

Sulphite Pulp.—The two most important chemical processes for making pulp are the "sulphite" process and the "soda" process, both used principally in reducing coniferous wood to pulp, although the soda process in a somewhat modified form is used in treating straw, if intended for high grade papers, and in England for esparto. In the sulphite process the wood is prepared as for the ground wood process. The prepared blocks of pulp wood are then "fed" lengthwise to a "chipper" or set of knives which, revolving with great speed, transform the wood into small "chips." The purpose of this is to facilitate the permeation of the wood by the "liquor" in which the chips next are immersed in the "digester." The digester is a massive upright stationary steel vessels of an average capacity of from eight to 20 tons of wood, usually lined with cement or other material unaffected by acids. The liquor with which the digester is filled after the chipped wood is introduced is a solution of bisulphite of lime. The making of this liquor is an important feature of this process as upon its correct chemical composition the quality of the pulp largely depends. It is made by passing the fumes of sulphur burning in especially designed "retort furnaces" either into a "tower" filled with limestone over which water is trickling or through "tanks" containing lime in solution with water. The result in both cases is the formation of a solution containing bisulphite of lime, and usually a small percentage of bisulphite of magnesia. Hence, the name "sulphite" pulp. After the digester is filled with chips and liquor it is closed hermetically, steam is forced in under pressure of 80 to 100 pounds and the chips are allowed to "cook" from 8 to 12 hours. Then the contents are discharged into "blow-pits" or vats beneath. These blow-pits have perforated bottoms through which the sulphite liquor drains away; and the pulp is washed by a stream of water which removes all traces of the liquor. The pulpy mass is then screened and pressed and put up in laps, similarly to the manner in which ground wood pulp is treated. In the

process of "cooking" the intercellular portions of the wood are dissolved and the nearly pure cellulose fibre remains. Much care is necessary to stop the cooking at just the right point so as to leave the fibre properly freed from the surrounding substances, but unimpaired in strength. A process producing a sulphite pulp of superior strength and quality is made by a longer cooking (48 hours) at a much lower steam pressure (15 pounds). The bulk of the wood is reduced nearly one-half, whereas in the ground wood process both the cellulose and intercellular matter are preserved and the prepared wood (dry) and pulp are nearly the same, weight for weight, the only loss being in the mechanical process of removing the imperfectly ground wood. For high grades of paper "sulphite" is bleached. The sulphite liquor is put to a practical use in tanning; or is fermented and distilled, producing 15 gallons of 95 per cent alcohol for each ton of wood pulp made.

The Soda Process.—For this purpose poplar, basswood, beech and similar deciduous woods are used. The wood is prepared in chips as already described and cooked in lead-lined digesters, generally stationary, containing an 8 per cent solution of caustic soda. Steam at 100 pounds pressure is admitted and the cooking is continued for 8 to 10 hours. The pulp is discharged into iron tanks and "washed" thoroughly — to remove the freed organic matter and the alkali. The washing is so done as to use a minimum quantity of fresh hot water, as the "recovery" of the soda from the liquor used in washing is an important feature of this process. It is so successfully performed that in some mills as high as 90 per cent is recovered. The liquor is first "evaporated" under a partial vacuum by steam until it is of about the fluidity of melted pitch. In this state it passes into a revolving drum-like "furnace" where combustion is set up by means of a flame from an adjoining fire-box, burning wood or coal, which coming in contact with the pitchy liquor ignites it. The residue is a "black ash" which is then causticized with lime and becomes suitable for use again. After thorough draining the pulp goes to screens which remove coarse fragments and dirt, and thence to the machine which converts it into "half-stuff board." Soda-pulp, partly on account of the nature of the wood itself and partly on account of the drastic treatment, is of a much softer quality than sulphite, has a shorter fibre and, therefore, less strength and the yield is less per cord of wood, rarely exceeding 50 per cent. It requires bleaching to fit it for use in all except dark-colored papers, as without bleaching it is of a brownish color. This process is conducted while the board is still wet, by subjecting it to the action of a bleaching powder bath at a temperature of 60° F. for from four to six hours. Or an electrolytic bleach may be employed. It is then thoroughly washed in drainers to remove every trace of chlorine.

Sulphate Pulp.—In this process only pine is used, and the liquor in which it is boiled is sodium sulphate. In some mills a proportion up to 30 per cent of caustic soda is added. The boiling continues for 30 hours during which the sulphate becomes sulphide. The formation of hydro-cellulose is encouraged, and the resulting pulp makes a very strong and tenacious paper.

Straw Pulp.—The straw of wheat and rye afford the most suitable fibre for straw paper, although oat straw is also much used on account of its long fibre, being generally mixed with wheat fibre. The yield from the raw material is about 40 per cent of cellulose. It is first put through a chopper which cuts it into small pieces in which condition it is carried by an air-blast to a sieve where the straw is caught and the dust and dirt carried along on the blast. Thence it goes to the boilers where it is charged with from 12 to 16 per cent of caustic soda. Under a pressure of 60 pounds of steam and at a temperature of 300° F., it is boiled for six hours, at which time it is in the "half-stuff" condition, and will flow readily through a pipe into the Hollander, where it is washed and disintegrated. Esparto and other grasses receive practically the same treatment, but do not require so high a boiler pressure nor so long boiling. All of these grass fibres are bleached—usually in the breaker.

Bamboo Pulp.—The successful development of a treatment of bamboo fibre which makes it available for an excellent quality of book paper adds enormously to the paper sources of the world, as it is estimated that bamboo constitutes about 80 per cent of the total of all wood growths. The stems are crushed and chipped to small fragments which are first boiled in hot water to remove an objectionable starchy filling. They are then boiled with a 20 per cent solution of a combination of three parts caustic soda and one part sulphide at 170° F. under 120 pounds pressure for one hour, and at 162° and 80 pounds pressure for four or five hours longer. The yield of dry pulp is about 45 per cent of the dry weight of seasoned wood.

Rags.—Cotton rags, consisting as they do of the nearly pure cellulose fibre and linen rags, being composed of fibres which have already undergone a treatment of maceration and "retting" to remove the intercellular matter, have only to be "cleaned" and separated into the individual fibres to prepare them for paper-making proper. The cleaning is both mechanical and chemical. The various preparatory steps are threshing, picking, sorting and cutting into small pieces. The last is commonly done by machinecutters, though for fine papers it is often done by hand. The cut pieces go to a duster, and for high grade paper are washed again. These pieces are next boiled from 12 to 18 hours under steam pressure of 45 pounds in a weak solution of quicklime or caustic soda, contained in revolving boilers, usually horizontal, called "rotaries." This "kills" the colors and "starts" the grease and dirt so that when the cooked stock is placed in a "washer," the impurities are readily separated, leaving the fibres quite clean. This washing is usually done in a "breaker" or "Hollander," which consists of a rapidly revolving iron "roll" mounted in an oval-shaped tub and set with dull steel "blades." The roll revolves over a "bed plate" and draws the "stock" through between the roll and plate, dragging the fibres apart while cleansing them. The Hollander is often made with two rolls operating in contrary directions. It is necessary, however, if the stock is to be used for high-class papers, to bleach them with some compound of chlorine. The "half stuff" is then

let down into vats or "drainers" where the liquor is allowed to drain off.

Converting the Pulp into Paper.—Paper-making, in the restricted sense, begins with assembling the pulps and other materials, and mixing them thoroughly, at the same time further disintegrating the fibres. This is done in a "beater" or oval-shaped tub of an average capacity of about 1,000 pounds of paper in which revolves a horizontal roll with steel blades on the surface, running parallel with the shaft after the manner of a paddle wheel. These knives are of varying design—zigzag, elbow, knee and similar angular shapes. As the roll revolves the blades draw the "stock" between their edges and a "bed plate" of steel, thus "dragging out" or separating the fibres. In some beaters the bed also is set with knives so as to produce a shearing action with those of the revolving roll. The character of the resulting pulp is determined in large measure by the sharpness or dullness of the knives. In the making of grease-proof and Kraft papers the roll is usually of stone, and the bedplate may also be of the same material, the action being one of grinding instead of shearing. The time required in the beater for the various papers and fibres is as follows: linen and cotton for bond paper, 10 to 12 hours; rags for writing papers, five to seven hours; chemical wood pulp for book papers, four to six hours; cheap printing and newspapers, one and one-half to three hours; soft cotton fibre for blotting paper, one to one and one-half hours. It is, therefore, obvious that the character of the paper to be made is very largely determined in the beater, and this becomes the most important of the paper-making machines. This fact has led to the invention of several forms designed for special manufactures. For the highest class of rag papers the beater is of the old Hollander type, than which none is better. For cheaper papers higher speed in the reduction to pulp is desirable, and devices to accelerate the mixing and circulation of the components of the pulp have been added. In order that the machine may be used for different types of paper, the bedplate in some makes is in removable sections which may be replaced with others to produce a different quality of pulp, and the knife rolls also may be changed.

It will suffice from this point onward to describe the process of making news paper which is essentially the same as in all kinds of paper with certain modifications of which the most important will be noted. The beater is "furnished" with sulphite pulp and ground wood pulp in the proportion of about one to three. Other kinds of paper have their appropriate "furnish." Sometimes a small percentage of kaolin, calcium sulphate (gypsum), barytes or other mineral "filler" is used, the quantity varying with the kind of paper to be made. In recent practice starch, formerly in use as "size," has become an important filler. Its high cost, however, restricts it to high. The filler improves the color, surface, opacity and "feel," and improves its printing properties. "Size" which is resin in a saponified form is added and has the effect in the final drying process of forming a kind of "varnish," rendering the paper less absorbent. It also helps "fix" or hold the "filler," increasing the strength,

Coloring matter, which in news paper is generally "aniline blue," is put in, usually in solution, the object being the same as that of adding bluing to a batch of newly-washed clothes in the laundry—to give distinct whiteness. In the finest papers ultramarine and cochineal are the dyes used. When cream or pinkish shades are desired appropriate dyes are employed. In making colored cover papers and similar stock the matter of dyes is of much greater importance, and the whole series of permanent mineral and vegetable dyes are drawn upon. (See DYES). A scientific selection must be made as certain paper stock will absorb satisfactorily only dyes of acid reaction, while other "stuff" will require basic dyes. Often the best and most permanent results are obtained only by a combination of dyes of both reactions, the basic dye precipitating the acid dye. Basic dyes are as a rule of less permanency than acid dyes, but give higher brilliancy of coloring.

The coal-tar dyes most largely in use in paper making are the following:

	Basic Dyes	Acid Dyes
Yellows	Auramine Chrysoidin	Metanil yellow Quinoline Naphthol yellow Naphthol orange Paper yellow
Reds	Magenta Grenadine Rhodamine	Eosine Cotton scarlet Metanil red
Blues	Methylene Victoria New blue Paper blue	Soluble blue
Greens	Brilliant green Malachite green Diamond green	
Browns	Bismarck Vesuvine	
Violets	Crystal violet Methyl violet	Acid violet
Blacks	Jet black Coal black	Brilliant black

The prevailing practice in "furnishing" the beater is to add to the pulp first the loading, then the dye, then the size of resin, etc., and finally the alum, mixing in thoroughly each component before the next in course is added.

Alum is added as a mordant to "set" the color and also to "free" the resinic acid in the size and "set" or deposit it. The term is a technical one as ordinary alum is no longer used, but aluminum sulphate. After a thorough mixing in the beater the pulpy mass or "stock" is usually passed through a "refining engine," the most common type of which is known as the "Jordan." The purpose of the Jordan is to supplement the brushing out and mixing which has already occurred in the "beater" and to shorten the fibres if desired. It consists of a cone which revolves in a stationary conical case, the outer surface of the cone and inner surface of the case being set with numerous blades, the two sets of which can be made to approach as near each other as desired. The relative position of the blades determines the

length of the stock which continuously passes between them. After leaving the "Jordan," the stock is "screened" and then pumped upon the paper machine proper, having been thinned or diluted at various points of its passage so that when it comes upon the machine it behaves in all respects like an absolute fluid. The Four-drier machine on which all news paper is made may be divided into the "wet" part and the "drying" part. On the wet part of the paper is "formed" and given a consistency which properly entitles it thereafter to be called paper, the rest of the process consisting in still further increasing its consistency, drying it, giving it surface, etc. The liquefied stock, having come to the machine, flows from the "head box" through a wide aperture or mouth over an "apron" of waterproof cloth, and upon an endless horizontal wire cloth moving forward continuously. The relative rate of "flow" and "speed" of the machine determine the thickness or ultimate weight of the paper. The speed of the stock sideways is limited by two endless rubber bands about one inch square called "deckles," one at each edge of the "wire." In modern fast-running news paper machines the width of the web may reach to 200 inches. In the machines making the better class of book paper and writing papers the widths are generally somewhat less than 100 inches. The length of the endless wirecloth belt varies from 60 to 100 feet, the distance of travel, therefore, from the apron to the couch rolls being from 30 to 50 feet. The speed of travel of the wirecloth belt varies widely according to the quality of the output. High-speed news machines make up to 500 feet per minute. Machines which make good writing paper run about 60 feet to the minute. The cloth of which the wire belt is made has about 60 or 70 meshes to the running inch.

As the pulp flows on to the wire it contains 90 per cent, or more, of water. The water immediately begins to drain off through the wire and the fibres to deposit upon its surface. Through various devices so much of the water is removed that when the film of fibres reaches the point where the wire returns on its backward course, it is sufficiently compact or "felted" to be separated from the wire and conveyed by "felts" to and through the "presses" of which there are two or three. The presses are massive rolls in pairs, the paper supported by woolen endless "felts" passing between them. After this the paper readily carries itself and, passing over a short gap, it enters the "dryers." They are cast-iron cylinders from 20 to 30 in number varying on different machines from three to four feet in diameter, arranged in two horizontal tiers, one above the other. The paper passes partially around each dryer, going alternately from one tier to another, conveyed by endless canvases called "dryer felts," which serve to press the paper against the surface of the dryers heated by a constant passage of steam inside. Returning to the first formation of the sheet it is interesting to note the variety of means employed for disposing in the quickest possible time and within the most limited space of the vast amount of water in which the fibre is at first suspended. First, gravitation draws the water through the wire cloth. This is facilitated by a large number of small "table" rolls immediately under and supporting the upper

part of the wire which, as they revolve, tend by capillary attraction to carry away the water and thus hasten its flow through the wire. The "shake" which gives to the wet end of the wire a lateral movement back and forth, intended to distribute the fibres evenly and prevent their arranging themselves longitudinally or in the direction of the flow, tends also to hasten the draining off of the water. A slight grade upward toward the couch roll also aids in an equal distribution of the pulp. This grade is adjustable so that the character of the deposit may be controlled. The wire, carrying the paper, passes over a series of "suction boxes" which have perforated tops and are subject to the action of exhaust pumps. The water is drawn through the wire and away through the suction boxes. Before the paper leaves the wire, it passes under a heavy "couch roll" which both presses out the water and by reason of being covered with a "jacket" of felt with exceedingly long nap, constantly absorbs water of which it is ingeniously rid by a "guard." A recent improvement is a hollow suction couch roll. The "wet" presses act in the same way as the couch roll, pressing out and absorbing more water. But notwithstanding all these devices, the paper reaches the dryers with usually not to exceed 30 per cent of stock in the sheet, the rest being water which has to be dried out as the paper passes over the dryers at the rate often of 500 feet a minute. Water marks are produced by a "dandy," a skeleton cylindrical roll covered with wire cloth, mounted over the "wire" between the first and second suction boxes, and resting on the web of paper. The design for the water mark is raised on the surface of the dandy and impresses itself on the paper. "Laid" paper is made with a dandy so covered with wires as to make an impression of parallel lines running lengthwise about an inch apart crossed at right angles by lines quite close together. The dandy also helps "form" or solidify the paper. In passing through the drying cylinders the paper web is carried on endless belts of dry felt, which serve to keep the web smooth and tight and prevent cockling. The number of drying cylinders of the Fourdrinier machine varies according to the type. On high-speed news paper machines there may be as many as 36 drying cylinders; on the slower fine-paper machines there are rarely more than 20. The diameter of these cylinders ranges from 48 to 60 inches, and they are arranged in series, usually with a pair of heated steel smoothing rolls of small diameter near the end. The drying rolls are heated by steam, the temperature gradually increasing toward the end of the series. As the web shrinks in drying, the rolls in a series are of successively smaller diameter, so that the relative length of the surface traversed shall be that of the drying web.

Machine or Tub-Sizing.—Fine papers, besides sometimes being "sized" in the beater, are usually sized on the paper machine, the web passing through a "tub" of some heated gelatinous mixture ("animal size"). This tub is a long vat placed between the two series of drying rolls. The paper web is floated on the size and thence passes to a pair of rolls which squeeze out the excess, and so through the remaining drying cylinders. The paper is either dried (1) wholly on the machine or (2)

partially, and then after being cut into sheets is hung in "lofts" to complete the drying. Although the web when it leaves the dryers is uniformly smooth, it lacks the quality of surface desirable in printing. It is, therefore, passed through the "calenders," a series of chilled-iron rolls with polished surfaces arranged in a "stack," the paper going in at the top and passing out at the bottom to the "reel." This is practically an ironing process and by the regulation of the pressure of these calender rolls the requisite amount of "surface" is given to the paper. Book and fine papers are often "supercalendered" or passed through a second stack of calenders after the paper has been taken from the paper machine.

Coated Paper.—To meet the requirements of certain kinds of presswork, some papers are "coated" on one or both sides with china clay or other mineral substance, which gives an exceedingly smooth surface without the hardness of supercalendered papers.

Cylinder Machines.—The distinguishing feature is the use of a drum covered with wire (instead of the horizontal endless wire of the "Fourdrinier") which operates the same as the pulp press, already described. Several cylinders can be used on the same machine, each making a separate web, all of which are brought together before passing into the press, thus making paper of as many "plies" as there are cylinders. This principle is taken advantage of to make composite papers, one ply being of one quality, another of another, and also to make very heavy papers.

Cutting.—When the paper leaves the calenders and is reeled, it may be considered to be made. All that remains is to trim off the rough or "deckle edges" on the "slitter" where as it unwinds from the reel it passes between rapidly revolving knife-like discs. If it is desired to divide the width of the sheet it is done at this point by adding one or more sets of "slitter blades" according to the number of divisions of the sheet desired. Finally comes the "winder." If the paper is intended to be marketed in rolls it is wound on either an iron "core" or, as is now more usually the case, on a core made from heavy tough paper, until the desired diameter is reached, when the rolls are taken away to the "finishing" section where they are "finished," that is, wrapped in stout paper securely pasted and marked. They are then ready for shipment. "Sheet" paper was formerly cut into sheets by a "cutter" attached to the paper machine, but as the speed of the machines has increased this practice has been almost entirely abandoned and now it is usual to run the paper into rolls which are taken to the finishing section and cut into sheets on a cutter, the sheets then being "counted" and done up into "bundles."

Sizes.—In the United States, if not elsewhere, the paper-maker has so conformed to the various demands of the consumer that standard sizes which were originally adhered to are, except in the case of writing papers, almost obscured by the great variety of special sizes. Four-fifths of the news paper is in rolls varying in length of roll (that is, width of web or sheet) usually from 30 inches to 75 and in diameter from two to three feet. The International Paper Company exhibited at the

PAPER

Types of Modern Paper Machines

PAPER

Interior View of Coating Department of a Modern Paper Mill

Buffalo Exposition the largest roll ever made, being 152 inches in length and weighing 4,000 pounds, and the sheet unrolled would reach six miles. Some of the common standard sizes of news sheets are, in inches, 20×30 , 24×38 , 30×40 , 32×44 , etc. The sheets are put up in bundles generally of two reams of either 480 or 500 sheets to the ream and are either "folded" in quires or put up "flat" or "lapped" (one ream dovetailing into the other). Book paper is generally in sheets, although the use of web presses requiring rolls is extending to book and magazine publishing. The sheet sizes are many of them the same as news paper. The principal sizes of fine papers are antiquarian, 31×53 ; cap, 13×17 ; double cap, 17×28 ; columbier, 23×34 ; crown, 15×19 ; demy, 16×21 ; double demy, 16×42 ; elephant, 23×25 ; imperial, 23×31 ; post, commercial, 11×17 ; double post, $19 \times 30\frac{1}{2}$; folio, 17×22 ; double folio, 22×34 ; royal, 19×24 ; super-royal, 20×28 . Wrapping paper and boards are furnished in both standard and special sizes. In recent years wrapping paper to a considerable extent has been prepared for the market in what are called "counter rolls," which are set upon the counter in a frame and torn to the size needed for the particular parcel to be wrapped.

Hand-made Paper.—The "hand" process came into existence at a very early period and still survives in some countries, notably in Japan. But the output of hand-made paper is very limited, except in Oriental countries, where, in contrast with the high development of the art elsewhere, the adherence for centuries to this antiquated process is a striking mark of their backward civilization. The method of making paper by hand has remained practically the same as it was more than 2,000 years ago. The pulp is diluted with water in a vat in which is immersed a "mold" or rectangular frame, on the top side of which are stretched parallel wires near together with others at right angles (woven wire cloth is now generally used). Upon this "mold" is tightly held a "deckle" or wooden frame. On withdrawing the "mold" from the vat in a horizontal position, the water within the deckle drains off, leaving the wires coated with fibres, the operator meanwhile shaking the mold so as to evenly distribute them. The film of fibres or paper is then stripped from the mold and laid upon a felt. Paper and felt are piled alternating, forming a "post," which is then pressed to extract the water.

HISTORY.

The existence of papyrus has been traced back to 2400 B.C., and no doubt it then had been in use a long time. In China and other parts of the world a similar article, made from rice stalks in practically the same way, is known to have been in use several hundred years B.C., and is supposed to have come down from a time even then remote. The Egyptian papyrus—the material, but not the art—was introduced probably about 325 B.C. into Europe as a consequence of the conquests of Alexander of Macedon and was used there very generally until the 8th century, when, together with parchment, it began to be replaced by paper made quite differently upon a principle which has survived to the present day.

Early Paper.—Papyrus is lost sight of in the 12th century. The new paper was of Asiatic origin. Its fundamental difference from papyrus was that the raw material in making paper was first reduced to pulp, that is, the natural structure was broken down so as to separate the component fibres, which were then rearranged to form a lamina or thin sheet. In China, Formosa, Korea and very likely elsewhere in eastern Asia this principle was used certainly before the Christian era. Though, as Pliny truly says, "the remembrance of past events depends upon paper (papyrus)," with the irony of fate, paper has failed to record its own origin, and much of the early history of the art is left to conjecture.

As early as 156 B.C. the Chinese made pulp from the small branches of the mulberry tree, various barks, bamboo, leaves, etc. In Korea the paper mulberry was chiefly used and the Japanese having begun to cultivate this tree made paper from it about 610 A.D. It is still to-day almost the only raw material used by them. The portion used is the inside bark. The probable course that paper-making took was from China and other Oriental countries to the eastern extremity of the Mediterranean (Persia and Arabia, about 620 A.D.), whence the Saracens carried the practice of the art to Spain after their conquests of that country in the 8th century. The consequent disruption of commercial relations with the Egyptians cut off the supply of papyrus and facilitated the substitution of true paper in Spain and other parts of Europe. Paper from Damascus had at about the same time found its way into eastern Europe, but the first paper mill in Europe was established by the Saracens in Spain. It appears that the Saracens used cotton for paper from a very early time and were probably the first to find that old cloth fabrics also answered the purpose very well. In Spain flax was the first material used and then cotton. The paper imported into Europe from Damascus was likewise made of cotton; 1085 is set as the date when "rags" were first used in Spain and 1100 for the first appearance of linen paper. The spread of the industry throughout Europe was slow, and its route and early development cannot be surely traced. Italy had its mills soon after Spain; France first learned to make paper in 1189; in Germany the first mill was built in 1390, while for the beginning of paper-making in England 1330 is given as an uncertain date. The western hemisphere was reached in 1690, when a mill was erected at Germantown, Pa., by William Rittenhouse. It is a curious sequel that to-day there is absolutely no paper made in Egypt, which supplied the civilized world for so many centuries with papyrus, and that the Chinese and other Orientals who contributed the fundamental principles of modern paper-making have made little or no progress themselves in developing the art. Although they have characteristically adopted Western machinery to a limited extent, they still in the main cling to archaic methods of making paper, which in that country is of slight commercial importance. The industry is now practically confined to Europe and North America. From the time rags began to be used in Europe, they rapidly displaced other materials on account of the economy of the double use of the fibre. Rags held sway in the paper industry for many

centuries, but not entirely to the exclusion of numerous other materials. Esparto (q.v.), which is a Spanish grass, containing an especially good fibre, and other similar grasses, as well as straw, have long been used. In 1765 Schaeffer of Ranslon published a book printed on 60 varieties of paper made from as many different materials. Somewhat more than 100 years ago, under the stimulus of greater demand, the substitution of machinery for manual labor and the development of chemistry, attention was directed afresh to the use of fibre derived directly from the original growth as a substitute for rags. An impetus was given to the manufacture of paper from straw (first used about 1800), which has made it until recently an important factor in paper-making. In 1719 Reaumur first suggested the use of wood. Sporadic experiments to this end were made, but without noteworthy results until finally they culminated in the present mechanical and chemical processes of producing pulp from wood. Since it has been demonstrated that paper can be made from almost any kind of vegetable fibre, it only remains to discover new methods of treatment or improvement in old methods which will render more varieties of fibres commercially available. It is thus merely a question of cost of material and of conversion.

Processes of Manufacture.—Leaving out of consideration papyrus and rice paper, the reduction of the raw materials to pulp has always been a preliminary to making the paper. So far as we know this was done by the Chinese and kindred nations, the first pulp-makers, by beating the raw materials into a pulpy mass, with simple hand tools. They also at a very early date disintegrated the materials by either soaking them or boiling them in lyes. They thus originated two processes of making pulp which, though much modified, are still in vogue. As the Japanese and Chinese still depend principally upon hand implements for macerating the raw materials, we must look elsewhere for the earliest application of machinery for this purpose. Whether paper-makers used machinery before the introduction of rags is not clear, but it is highly probable that they did. Certainly machines driven by water power were in use soon after the adoption of rags. They were a sort of trip hammer which pounded the rags into pulp. In the first mill erected in Germany in 1390, such a machine driven by water power was used to prepare rags. Water power was also used in a paper mill in Tuscany some time in the same century. Whether at first rags were "cooked" before being beaten is not certain, but it was not long before it became customary to so treat them. The fabrics were first weakened with caustic and then macerated in a "beating engine." The "Hollander engine," the precursor of almost all modern types, was invented in 1750, and essentially as originally designed is still used. The greatest advance in the history of paper-making was made when toward the close of the 18th century a machine driven by power and making paper continuously was substituted for this single-sheet hand process. Modern paper-making may be considered to date from that time. Roberts, a Frenchman, working in a hand paper mill in France, is credited with this invention,

and in 1799 his machine was installed by François Didot at Essone, France. In 1803 Fourdrinier and Donkin introduced essentially the same machine into England, where it was put into successful operation in the following year. That machine, in principle the same as those in universal use to-day, is known by the name of Fourdrinier, the maker, but not the inventor. It multiplied the productive capacity of labor enormously. Although a continuous web of paper was produced, it was invariably cut into sheets, for it was nearly 100 years before the invention of the web printing-press created a demand for paper in the form of rolls. Second only in importance to Roberts' invention was that of Dickenson, an English paper-maker, who, in 1809, invented the "cylinder" machine, a modification of the "Fourdrinier," which has played an important part in the manufacture of wrappings, paper boards and generally the coarser grades, while the Fourdrinier is supreme in the book, news and writing-paper fields. The machines in use in the United States were:

In 1872, Fourdrinier	299.	Cylinder	689.
In 1900,	663,	"	569.

Great improvements have been made not only in the paper machines proper, but in the other machinery used in pulp and paper-making, and the use of raw materials has been revolutionized so that paper-making as a whole made an enormous stride since the day of Roberts, but still his time must be regarded as an epoch in the history of the industry.

Growth of the Industry.—The earliest use of paper was for writing purposes. As the art of writing was for so many centuries confined to a small portion of the world's population, and as few copies of books were made, the consumption of paper must have been very limited compared with many other commodities. But the invention of printing which led to the manifold production of books gave a great stimulus to the industry. It is probable that the use of paper for numerous mechanical and practical purposes is of comparatively modern origin except that it has always been used more or less for wrapping. But paper was too much of a luxury to be used freely for wrapping until recent times, and even now, for example, in Italy as a usual thing frugal shop-keepers do not furnish wrapping paper, and not uncommonly the buyer, if he wishes his parcel wrapped, takes with him the paper, usually an old newspaper or sheets from a child's copy book; these he uses as long as they will hold together. There has been at all times a reciprocal relation between paper-making and many other arts and industries, progress on the one side stimulating progress on the other. Thus, for example, improvements in printing have not failed to meet a response from the paper-maker with cheaper product. The use of web presses for printing newspapers has stimulated improvements in the process of making paper which reduced its cost and the reduction in price in turn has been a very important factor in the growth of the printing and publishing industries.

The production of paper is now centred principally in the United States, England, France, Austria-Hungary, Belgium, Holland and Scandinavia. These countries lead both in

the methods of manufacture and the quantity of output. In general there is a striking relation between the intelligence and progressiveness of a country and the quantity of paper consumed. It follows as a corollary that the United States has a greater per capita production than any other country. The total number of paper mills in the world is between 4,000 and 5,000, including numerous small establishments in China, Japan and other Oriental countries, where paper is made mostly by hand, but no reliable statistics exist to show the total production of the world. A rough estimate would make the world's production upward of 9,000,000 tons annually. This is approximately three times the world's annual growth of cotton; the significance of this comparison is that it indicates the insufficiency of rags as raw material and the importance of the inventions which have led to so general a use of wood pulp.

Modern Conditions.—If we take the United States as a type the most important factors in paper-making are raw materials (spruce and poplar wood, rags, straw and old papers), water power and fuel. About three-quarters of the total tonnage of paper made in the United States is composed of wood pulp. The percentage made from rags is very small, not more than 5 per cent or 6 per cent, but the value of the rags used in the last census year was \$6,595,000 as compared with \$9,837,000, the value of the wood used, demonstrating that rags are used chiefly in the highest grades of paper. Water power is not only indispensable for making ground wood pulp but is generally relied upon to drive the beating engines and other heavy machinery. Coal is required principally for producing heat to dry the paper, but also for additional power.

Other important conditions affecting the production of paper are the existence of good transportation facilities and the proximity of large markets. All these factors combine to put the United States at the head of the paper-making countries. An advantage which American ingenuity itself has created is the superiority of its paper machinery, especially in point of capacity; American machinery being, as a rule, larger and operated at greater speed than that of other countries. It is this fact that more than compensates for the much higher scale of wages prevailing here than in any other paper-producing country, even after due allowance has been made for the superior character of American workmanship. The machine tender, for example, who receives \$3 and upward a day in the United States, in England receives \$1.66, in Germany \$0.75, while in Italy, Scandinavia and other countries even less. The exporting of American paper machinery has a decided tendency to neutralize the advantage that the United States paper-maker might have if it could be kept for his own exclusive use.

Combinations.—The most striking of recent changes in the industry in the United States is the consolidation of many mills under one ownership and management. Already a majority of the "news," "writing" and "boards" mills have thus come together, forming the largest companies in the world in their respective branches. There is a national organization of paper manufacturers of the United States known as the American Paper and Pulp Association, founded in 1878.

Production.—The special census of manufactures taken for 1919 showed that in that year the total number of establishments in the United States engaged in making paper of all kinds, paper boards and wood pulp was 729. Of these, about 495 made paper exclusively; about 160 made both wood pulp and paper; and the remainder made pulp exclusively. These 729 concerns were capitalized at \$905,794,583, and employed 113,759 hands to whom they paid in the year \$135,690,642 in wages. The raw materials consumed by these factories cost them an aggregate of \$467,482,637, and the value of the products turned out was \$788,059,377. These products consisted of 1,323,880 tons of news paper in rolls and sheets, valued at \$98,559,359; book paper, machine finish, 532,413 tons, value \$76,772,582; book paper, sized and supercalendered, 286,407 tons, valued at \$41,498,194; coated paper, 132,454 tons, valued at \$24,009,614; plate, lithograph, map, woodcut, etc., paper, 9,821 tons, valued at \$1,556,372; cover paper, 22,163 tons, valued at \$5,643,191; fine papers, including ledger and highest grade, 30,584 tons, valued at \$12,254,967; pole dried, 48,564 tons, valued at \$19,868,978; air dried, 28,786 tons, valued at \$9,514,618; machine dried, 59,674 tons, valued at \$14,665,308; sulphite bond, 82,467 tons, valued at \$17,484,179; and all other fine paper, 75,108 tons, valued at \$13,952,756. Wrapping papers manufactured included: Manila (rope, jute, etc.) 111,782 tons, valued at \$15,493,141; heavy (mill wrappers, etc.) 118,755 tons, valued at \$9,856,002; straw, 5,895 tons, valued at \$457,606; bogus or wood manila, all grades, 126,175 tons, valued at \$12,047,371; Kraft, 192,583 tons, valued at \$26,575,194 and all others, 276,182 tons, valued at \$38,639,983. Boards included: wood pulp boards, 179,747 tons, valued at \$14,887,881; straw, 228,248 tons, valued at \$12,229,837; news, 88,839 tons, valued at \$4,604,082; binders, trunk and press, 43,091 tons, valued at \$3,787,860; leather board, 28,167 tons, valued at \$2,263,288; cardboard, bristol board, card middles, tickets, etc., 84,987 tons, valued at \$11,104,105; chip, 695,963 tons, valued at \$37,749,210; all other boards, 518,022 tons, valued at \$37,464,380. Tissue paper of high grade was manufactured to the extent of 31,025 tons, valued at \$11,137,550; white, colored and waxing tissue, 36,545 tons, valued at \$7,644,952; towel and napkin tissue, 19,266 tons, valued at \$5,144,895. The industry finds its greatest development in New York (16.4 per cent), Maine (11.1 per cent) and Massachusetts (11.9 per cent), Wisconsin shows an increasing interest (10.2 per cent), Pennsylvania (8.2 per cent), Ohio (7.0 per cent), Michigan (8.4 per cent) and New Hampshire (5.3 per cent) also contribute a substantial proportion of the country's total output.

Exports.—The paper export business of the United States was insignificant until 1878 when the "paper and manufactures thereof" exported amounted to about \$1,000,000. For the year 1923 the amount was \$25,498,200; and 19132 tons of wood pulp, valued at \$1,184,629.

PAPER CURRENCY. See CURRENCY.

PAPER INDUSTRY IN AMERICA. In 1690 William Rittinghuysen, an experienced paper-maker from Broich, Holland, entered into partnership with William Bradford (q.v.), the first American printer, and together they opened the first paper mill ever established on American soil. It was located on a creek since known as Paper-Mill Run, conveniently near Philadelphia, and here a very fair quality of paper was manufactured out of pulp made from the rags of the home-grown flax. As the colonists had no other paper mill for fully 20 years, when William de Wees opened a rival establishment in close proximity to the first one, the enterprise was a profitable one, in spite of the fact that the making of paper by hand—the only method known in those days—was a laborious and costly process. This primitive system was in vogue in America until 1756, when the first pulp-engine was introduced in this country from Holland.

Within less than 15 years, there were 40 mills in various parts of Pennsylvania, Delaware and New Jersey that were turning out an aggregate annual product valued at more than \$500,000. In 1794 another large mill was established at Troy, N. Y., by Websters, Ensign and Seymour, and, during the same year, a mill for the manufacture of coarse wrapping paper from the bark of the basswood-tree was opened at Fairhaven, Vt., by Matthew Lyon. This was the first establishment in the United States to attempt to make use of anything except rags for pulp.

In the ordinary paper mills the method of manufacture was still a crude process. To make paper the pulp was floated in vats, at the side of which stood the workmen, mold in hand. This mold was of wire cloth, around the outer edges of which a rim was formed by superimposing a thin frame called a "deckle," which prevented the pulp from flowing off, and left the water no other escape than through the bottom of the mold. Into this the pulp was dipped and, as the water drained away, the pulp was left in the form of a thin layer covering the bottom of the mold. At this point it was given to another man—a workman known as the "coucher"—whose duty it was to remove the mold. This was done by the application of a piece of felt to which the pulp adhered in the form of a thin sheet; a second piece of felt was then placed on top of this; to this felt another pulp-mold was applied, and this process was continued until the pile of alternate layers of pulp and felt had attained the requisite height. From this pile, or "post," as it was called, all the water was thoroughly expressed, and the pulp, separated from the felt, was pressed, and hung upon the "tribbles," or lines in the drying-room. This portion of the process completed, the sheets were still rough and somewhat like blotting-paper, so it was necessary to dip them in

size, and to press and dry them again, before they assumed the character of a finished product. Laborious as this method was, it was the only process known until after the beginning of the 19th century.

The first marked improvement in the art of paper-making came with the introduction of the Fourdrinier machine. This invention was originally conceived by Louis Robert, a workman in François Didot's paper-mill, at Essone, France. In 1799 he secured a patent for a process of making paper by an endless web-machine, but, as he was financially unable to carry such an idea into effect, he sold his rights to Leger Didot, who took the patent to London. In 1804 he persuaded two brothers, Henry and Sealy Fourdrinier, both wealthy London stationers, of the practicability of the scheme, and finally transferred his interests in the invention to them. As the result, the machine has since borne their name.

In the meantime the paper-making industry in the United States had enjoyed steady growth. By 1810 the number of mills had increased to 185, and their annual product was valued at more than \$800,000. Already the demand for rags had become so great that the manufacturers, finding the domestic supply utterly insufficient, had commenced to import them. In 1817 the first power-mill in the country began operations at Pittsburgh, Pa., and, about the same time, Thomas Gilpin and Company, of Wilmington, Del., commenced to make paper by machinery. These machines, however, were of American invention.

Although the Fourdrinier machine was in use in England as early as 1806, it was not introduced in the United States until 1820. That it had revolutionized the making of paper there could be no doubt. By its use a seven-vat mill which had previously been operated at an annual expense of \$13,000, could now be run for a sum not in excess of \$3,600, and yet, while the American manufacturers knew all these facts, the cost of such machines was so great that they hesitated to introduce them. The machine utilized an endless web of wire cloth. As it revolved a stream of liquid pulp flowed over it evenly, the precipitation of the water through the cloth being so nicely adjusted that it was completed at the very moment in which the pulp-sheet met an endless belt of felt, which not only removed the pulp from the wire, but bore it on, through the heavy metal rolls which pressed it, separated it from the felt, and passed it over the steam-heated cylinders upon which it was dried, expelling it, at last, in a condition ready to be polished and cut into sheets.

As rag pulp is still used in the making of expensive grades of paper, the preliminary process to which rags are subjected is interesting. First cleansed and softened by being boiled in a strong lye of caustic alkali or lime, the rags are then placed in a washing machine, in which a heavy cylinder, with knives attached, partially macerates them. Everything except the vegetable fibre itself is then removed, a solution of bleaching powders is added and the mass is left in stone vats to bleach as long as may be necessary. This process completed, the substance left is taken to the beating engines, where, after it has been thoroughly washed with water to remove all trace of the chlorine, it is reduced to

pulp and transferred to the Fourdrinier machine. Of course, during the past hundred years, so many changes have been made in this mechanism, so many modifications and improvements, that it is difficult to realize that it bears any relationship to the original invention.

In 1809 an English manufacturer named Dickenson perfected another invention for making paper. It was called a "cylinder-machine," and differed from the prior invention by being fitted with a hollow, perforated, wire-gauze-covered cylinder, which operated directly in the pulp-vat by drawing out the water and leaving the sheets of pulp on the gauze, by which it was conveyed to the felt belt, and, thus, through the couching-rolls. In other respects it followed the principles of the Fourdrinier machine.

The American invention, which was first used in 1817, was of similar construction, but no other machine was known in this country until 1820, when the Gilpins imported machinery for making paper. In 1822 John Ames, of Springfield, Mass., invented a new cylinder-machine, and, in 1829, this invention had been so improved that its general use was assured. It was in this year that straw and grass were first used in making paper by Shryock, of Philadelphia; in 1830 the manufacture of Fourdrinier machines was commenced in Connecticut by Phelps and Spofford, and, in 1831, the discovery of the value of chlorine in cleansing pulp-fibre permitted the use of hitherto unavailable substances for paper stock. By 1850 there were only five mills in this country that still clung to the hand-made process of paper-making, and paper-machines had been so greatly improved that laid paper was, at last, produced by that method.

The general use of straw paper began in 1857. Some three years previous to this time, a Frenchman, A. C. Mellier, had succeeded in converting several vegetable fibres, notably straw, into pulp which he believed would be suitable for use in the manufacture of paper. The process, which has since borne his name, was neither a difficult nor a costly one. The straw was first thoroughly soaked, and, after it had been cleansed, was boiled, at a temperature of not less than 310° F., in a solution of about 4 per cent of caustic soda. Although Mellier peddled his idea from one end of the country to the other, the big manufacturers of paper did not seem to consider the scheme a practicable one, and three years, therefore, elapsed before he was able to persuade anybody to invest their money in his project. The man who finally undertook to manufacture paper by this process was J. B. Palser, a member of the firm of Howland and Palser, but the factory which they established at Fort Edward, N. Y., for the express purpose of carrying Mellier's idea into effect proved an excellent investment. In 1859 Palser himself patented some important

improvements upon the process, and from that day straw paper became one of the staple grades on the market. One of the direct effects of this innovation in the paper industry was the rise in price of rye straw. Of course, straw paper was by no means a perfect product, and was not entirely suited to many of the purposes for which it was used. Thus, for example, the silicious character of the straw was shown in the hard, brittle surface of the paper, a factor which alone represented a great disadvantage, from the printer's point of view, for such paper wore out type about twice as fast as the softer surfaced paper had done. Moreover, the glassy surface of the paper did not tend to durability, and yet, in spite of all these objectionable features, nearly all the newspapers were printed upon it, even until after the Civil War, but no great regret was felt when it was finally superseded by wood-pulp paper.

The quarter of a century that passed between 1830 and 1855 was largely an experimental period in the history of paper-making. During this time every substance that could possibly have possessed the requisite fibrous qualities was put to the test. Rags were out of the question, even straw was rapidly becoming too expensive, and other-fibres had proved generally unsatisfactory. In 1854 Wells and Burgess, of London, obtained a patent for a chemical wood pulp, and, a year later, Hugh Burgess, of Pennsylvania, invented a process by which the wood of the poplar might be used. The use of ground wood pulp dates from 1844, when a German, named Keller, invented a wood-grinding machine of such practicability that Voelter, the manufacturer, quickly purchased the invention. It was Voelter who first conceived the idea of grinding wood by stones and it is due to this development of the original machine that he is so commonly credited with having been its inventor. About 1847, having perfected his improvements, Voelter began to use the ground wood pulp, and, about two years later, the same system was adopted by the French manufacturers at Souche. The use of this material in the United States was first made by Alberto Pangenstecher, whose factory was located at Stockbridge, Mass., but, while he was very successful in making paper from ground wood, it was not put into printing-paper until 1867, when Wellington Smith, Warner Miller and William E. Russell adopted that process. Since the introduction of wood pulp, the paper industry has grown with great rapidity. Whereas, in 1850, the 500 mills, with their capitalization of about \$18,000,000, were producing paper to the value of about \$17,000,000 per annum, in 1870 the number of mills had increased to 669, and the annual production to \$48,436,935. The following table, compiled from the last report of the United States census, shows the status of the industry since 1890:

AMERICAN PAPER INDUSTRY.

	1890	1909	1914	1919
Number of establishments.....	749	777	718	729
Capital.....	\$89,829,548	\$409,348,505	\$534,625,000	\$905,794,583
Wage earners.....	31,050	75,928	88,857	113,759
Wages.....	\$13,204,828	\$40,804,502	\$53,246,000	\$135,690,642
Value of product.....	78,937,184	267,656,964	332,147,000	788,059,377

In these years the value of the production has increased over 10 times, while the capitalization has increased ten times also. During the years from 1880 to 1900, the pound price was slowly but steadily lowered. Since then it has increased, and some grades have reached the former level.

Of the 729 factories credited to the paper industry, over one-half make paper exclusively; the rest are pulp mills, or make both paper and pulp. They consume annually 5,477,832 cords of wood, mostly spruce, and one-half of this they import, chiefly from Canada. About 10 per cent of the pulp used is also imported, and 40 per cent of the sulphite fibre. Of the \$467,482,637 spent for materials, \$87,386,083 is for wood; \$68,996,470 for sulphite, and \$43,567,775 for old paper, which latter is mixed in with the new in the news print and other cheap grades of paper. Of the \$788,059,377 products, that classed as book is the largest, \$143,836,762, but this does not mean that this all goes into books, for this grade includes most of the magazine paper, and a large amount used for miscellaneous printing. The newspapers consume the greatest tonnage, but the quality is lower, and the annual value is about \$98,559,359; however, their illustrated supplements are often printed on book paper. The wrapping paper totals \$103,069,297, writing paper \$85,000,000, paper board \$121,000,000, tissue paper \$40,000,000, building and roofing paper \$18,000,000, wall paper \$6,000,000, and cardboard \$11,000,000. The balance is divided among the infinite variety of paper articles and objects supplied to the public.

A change in the paper industry of the United States came about shortly after 1909, owing to news print paper being put on the free tariff list. There is much more wood in Canada than remains in New England and the Central States, and labor also is cheaper there. Paper manufacturers began to invest in Canadian properties, and soon a large percentage of the American supply came from over the border. Then the World War came on, Canadian mills were short of help and curtailed production and the pulp supply from Scandinavia ceased. The result was a shortage of paper in the United States and prices went kiting. The newspapers and other publishers claimed that the manufacturers of paper squeezed the market, and an investigation followed, resulting in a fine of \$2,500 being levied on each of half a dozen men prominent in the paper combine. Thereafter the government took a hand, and large users of paper were notified that they must reduce the quantity utilized from 5 to 15 per cent.

PAPER PULP. See PAPER.

PAPHLAGONIA, pāf-lā-gō'nī-ā, in ancient geography, a division of Asia Minor, bounded on the north by the Black Sea (*Pontus Euxinus*), on the east by the river Halys, separating it from Pontus, on the south by Galatia and on the west by Bithynia. Besides the Halys (now Kyzyl-Irmak), the waterways were the Amnias (Goek-Irmak), and the Parthenius

(Bartin-Chai). The coast was fertile, the interior well wooded, game abundant, the principal industry sheep-raising, and the people famous horsemen. The region was subject nominally to Lydia, Persia and Macedonia in succession, still keeping its own actually independent princes. After Alexander's death Paphlagonia and Cappadocia became a part of Pontus, and then a Roman province. The chief city was the Greek colony of Sinope.

PAPHOS, pā'fōs, two ancient cities on the island of Cyprus. The earlier, called "Old Paphos" (Palæpaphos) was founded by the Phœnicians on the southwest coast near the mouth of the river Bocarus, possibly in the 10th century B.C., and was the sacred city of Aphrodite, probably not the Greek goddess but the Semitic Astarte, whose famous temple, the object of pilgrimage in the pre-Christian era, is now entirely destroyed, save for a fragment of the cyclopean masonry still preserved at Kuklia, the present town. The new city (Neapaphos), 10 miles northwest of the old, was a Greek colony, of great marine and commercial importance; in Roman times it was the capital of the island; it is now called Baffo. Consult Cobham, 'Bibliography of Cyprus' (1886); Ohnefalsch-Richter, 'Kypros' (1893); Enlart, 'L'Ile de Chypre' (1897, in 'Bulletin de la Société Géographique').

PAPIAS, pā'pī-ās, Christian writer, bishop of Hierapolis. He is described by Irenæus and later writers as a "hearer of John and a companion of Polycarp." He suffered martyrdom at Pergamus in 163 A.D. He was one of the earlier believers in the millennium, that is, the personal reign of Christ on earth for a thousand years after the resurrection of the dead, and was the author of five books of commentaries on the sayings of our Lord (Δόγων Κυριακῶν Ἐξηγήσεις), a few fragments of which are extant. It is from them that we learn that Saint Matthew's Gospel was traditionally believed to have been written in Hebrew, and the evangelist Mark to have been the interpreter or amanuensis of Peter in writing the Third Gospel. Consult Hall, 'Papias and His Contemporaries' (1899); Weissenbach, 'Das Papiasfragment bei Eusebius' (1874); 'Die Papiasfragmente über Marcus u. Matthäus' (1878).

PAPIER-MACHÉ, pāp-ī-ā' mā-shā, mashed or pulped paper made into some form other than the familiar paper sheets. It is usually mixed with glue, sizing or paste to give it greater hardness, and borax or phosphate of soda may be added as a fire resistant. It is commonly formed by forcing the pulped mixture into a mold under pressure and allowing it to dry. Wall ornaments, cornices, ceiling decorations and the like are frequently molded in papier-maché; picture frames and boxes, especially with ornamental tops as for snuff or the toilet table, or for souvenirs, are easily made in this way and may be colored or varnished at pleasure. Anatomical models and so-called wax figures may also be produced in this manner. Sometimes the papier-maché is made by pasting or gluing sheets of paper together and pressing them when soft into the form which it is desired to give them, but it is becoming more common to speak of such articles as being made simply of paper.

PAPILIO, a genus of butterflies (q.v.), popularly known as "swallow-tails" from the prolonged appendages of the posterior margin of the hind wings. The technical characters of the genus are found in the venation of the wings: internal vein of hind wing wanting, its place occupied by the submedian; median and submedian veins of fore wing united by a cross-vein, from the submedian end of which a short internal vein arises. The caterpillars are smooth and fleshy, and when disturbed protrude from the region of the thorax a pair of soft filiform "stink-horns" giving an offensive odor. The chrysalids are angulated and naked, and are suspended by a loop of silk passed about the middle and by a silken button at the caudal end. Although the imagos vary greatly, they are usually of large size and showy colors. Probably upward of 500 species are known, abounding in tropical countries; the genus is very poorly represented in Europe, but North America has nearly 30 species. Among our best known Eastern species are *P. asterias*, a handsome black and yellow form; *P. turnus*, with the wings a rich yellow bordered and barred with black, and *P. troilus*, generally rusty black with the posterior half of the hind wing greenish blue. The Ajax butterfly (*P. ajax*) is one of those interesting species which exhibit seasonal polychromatism. It sometimes resembles the *Asterias*. The *P. philenor* is another black species, but it lacks the yellow spots and shows a beautiful greenish reflection on the upper surface of the wings. The caterpillars of papilios are somewhat destructive to particular plants, but have not the economic importance of the cabbage butterflies (*Pieris*, etc.), which, like them, have the front legs well developed and are placed with them in the family *Papilionidae*.

PAPILLA. See SKIN AND SKIN DISEASES.

PAPIN, pā'pīn (Fr. pā-pān), **Denis**, French physicist: b. Blois, 22 Aug. 1647; d. England, about 1714. He practised medicine for a time at Paris, but turned his attention to physical sciences, assisted Huygens in the construction of the air-pump, and during a visit to England was admitted a Fellow of the Royal Society. Being a Protestant, the revocation of the Edict of Nantes prevented his return to his native country, and on leaving England he settled at Marburg, in Germany, in 1687, as professor of mathematics. But he again came to England in 1707. The real importance of Papin's many researches and experiments was long unperceived. He invented the double air-pump and the air-gun, a "digester" for cooking by means of liquids under produced atmospheric pressure, and the safety-valve, first used in the "digester." In 1690 he constructed the first steam-engine with a piston, and in the same year a boat with a paddle wheel revolved by a water-wheel supplied by means of a pumping-engine. Consult Thurston, 'Growth of a Steam Engine' (1878); Gerland, 'Life' (1881).

PAPINEAU, pā-pē-nō, **Louis Joseph**, Canadian politician: b. Montreal, Quebec, 1786; d. Montebello, Quebec, 24 Sept. 1871. He was educated at the Seminary of Quebec, studied law and was admitted to the bar, and was elected in 1812 to the Canadian assembly. During the War of 1812 he was captain of militia, and in 1815 he was elected speaker, which office he held for over 20 years as leader of the

French-Canadian party. He was continually at variance with the royal governors and in 1827 Lord Dalhousie adjourned Parliament and resigned rather than allow Papineau to take his seat as speaker. He disapproved the union of Upper and Lower Canada, and in 1834 framed the "Ninety-two Resolutions" which were sent to England in exposition of the grievance and demands of his compatriots. In 1834 he consulted with William Mackenzie, the revolutionary leader of Upper Canada, regarding the consolidation of their forces. In 1837 he attended the meeting in which a revolution was decided upon, and a warrant was issued for his arrest for high treason, though he had fled to the United States at the outbreak of the rebellion. He escaped to France, but was pardoned in 1845 and returned to Canada. He again entered Parliament in 1847, but finding himself without influence retired in 1854. Consult De Celles, 'Louis Joseph Papineau' (in *Makers of Canada series*, 1910); Read, 'The Canadian Rebellion of 1837' (1896); Kingsford, 'History of Canada' (1887-98).

PAPINI, pā-pē'nē, **Giovanni**, Italian philosopher: b. Florence, 1881. In his native city he founded a review, *Leonardo*, of which he became editor and to which he contributed several articles under the *nom de guerre* of Gian Falco. His philosophy is purely pragmatism, of which he is the ablest living exponent in his country. His published works are 'Il crepuscolo dei filosofi'; 'La cultura italiana'; 'Il tragico quotidiano: favole e colloqui' (1906); 'Il pilota cieco' (1907); 'L'Altra metà: saggio di filosofia mefistofelica' (1911); 'Le memorie d'Iddio' (1911).

PAPINIANUS, pā-pīn-ī-ā'nūs, **Æmilius**, Roman jurist: b. about 146 A.D.; d. 212. He accompanied the Emperor Septimius Severus as prætorian prefect to Britain and was put to death by Caracalla. Papinianus was the chief of all the Roman jurists. His most important writings were his 37 books of 'Quæstiones' (legal questions) and 19 of 'Responsa' (decisions). A few fragmentary portions exist as excerpts. These works were, until the preparation of the Pandects by Justinian, the main repository of jurisprudence connected with the exposition of original authorities. In the Pandects (q.v.) many extracts from him appear, forming about one-twelfth of the total number there given. Consult Brinz, 'Die Berliner Fragmente vorjustinianischer Rechtsquellen' (1884).

PAPPENHEIM, pāp'pēn-hīm, **Gottfried Heinrich**, COUNT. German military officer: b. Franconia, Germany, 29 May 1594; d. Leipzig, Germany, 17 Nov. 1632. He was educated at Altdorf and Tübingen, entered the army and as a colonel in the battle of Prague, 1620, was distinguished for his bravery. In 1623 he was appointed by the emperor to the command of a regiment with which he served in Lombardy until 1625, and in 1626 he crushed an insurrection in Upper Austria in which 40,000 peasants were killed by his forces. At Magdeburg with General Tilly in 1630 he is charged with great cruelty; he fought with Wallenstein at Leipzig in 1631, and was fatally wounded at the battle of Lützen in 1632. He was a man of indomitable courage, but rash and impetuous. Consult Hess, 'Gottfried Pappenheim' (1855).

PAPPUS, Greek mathematician. He lived at Alexandria toward the end of the 3d century of the present era. His great work, 'A Mathematical Collection,' is the source of all our knowledge of ancient Greek mathematics. Only a mutilated portion of the original eight books is extant and this contains, besides geometrical problems and theorems, an essay on mechanics. These fragments were published by Hultsch at Berlin in 1876-78.

PAPPUS, the downy appendage that crowns many single-seeded seed-vessels, such as the down of the dandelion, etc. It represents the calyx of the flower and may be pilose, with the threads unbranched, or plumose, with feathery threads; sessile, with the threads resting directly on the achenes; or it may be supported on a longer or shorter beak. It acts as a parachute in directing the fruit when it becomes separated from the parent plant. The term pappus may also be applied to other forms of a persistent calyx, as a crown or a circlet of scales.

PAPUA. See NEW GUINEA.

PAPUAN SUBREGION, a faunistic subdivision of the Australian Region which embraces the mountainous, heavily forested islands of the Papuan Archipelago, north of Australia. See ZOOGEOGRAPHY.

PAPYRUS. The word is derived from the Greek *παπυρος*, a reed plant known as *cyperus papyrus* or *papyrus antiquorum*, belonging to the family *cyperaceæ* (sedges). Its prolific growth in Egypt was utilized by the natives in ancient times for making a medium on which to write, also from its bark were made cordage and sails and its roots were used as fuel. Papyrus has been used as a medium for writing on from the very earliest antiquity; some specimens of papyrus documents found in Egypt are attributed to the third dynasty (4,000 years before our era). The ancient papyrus writings of the Egyptians are in several kinds of script: hieroglyphic, hieratic and demotic. Theophrastus (3d century B.C.) describes the Egyptian method of manufacturing paper from this plant. The stem was cut into two equal parts, from which, when the outward rind or bark was taken off, they separated the thin film, of which the stem is composed, with a sharp-pointed instrument. The pellicles or thin coats, being flaked from the stalk, they laid upon a table two or more over each other transversely and glued them together, either with the muddy and gelatinous water of the Nile, or with fine paste made of wheat flour; after being pressed and dried they made them smooth with a roller, or sometimes they rubbed them over with a solid glass hemisphere. These operations constituted the Egyptian papyrus as far as the art of making it has been discovered. The size of this paper seldom exceeded two feet in length, but it was often smaller; it had different names, according to its size and quality. The largest was termed "Imperial," which was also the finest quality. This was used for letter paper by the more prominent Romans. The next kind the Romans termed "Livian" paper and it was named after Livia, wife of Augustus; this kind measured 12 inches each leaf. A third kind was named "sacerdotal" and its size was 11 inches. The papyrus in use in the amphitheatre was nine inches in size. This writing

material became so popular among the ancient nations that its production became the chief article of commerce of Egypt, Alexandria being its chief centre. Many ancient manuscripts (called *diplomas* in paleography) have been unearthed in Egypt, especially at Fayoum (see MANUSCRIPTS). The papyrus plant and the documents written on this medium were both termed *charta* by the Romans. When the Egyptian manufacture of papyrus was at its greatest commercial height (it had become a monopoly) each leaf had to be marked with a stamp to maintain its authenticity and value. The Egyptians generally made it up in a roll (*volumen*), in lengths up to 46 feet and a width never exceeding 10 inches. The papyrus that was in use in Europe was of Egyptian importation up to the end of the 10th century. For a long period all diplomatic instruments were written on papyrus because of its beauty and adaptability, the sheets being fastened together to any required length. Parchment gradually superseded papyrus in the 7th century, and the discovery of paper-making lessened the demand for papyrus still more. Paper was made in Egypt probably as early as 600 A.D. from cotton. The pontifical chancellery, till the middle of the 12th century, used papyrus in issuing its bulls; the Merovingian kings wrote their documents on papyrus all through the 7th century; and we find in France documents inscribed on papyrus up to the end of the 8th century. While papyrus was poorly fitted for use as book (*codex*) pages and made up into a roll (*volumen*) for this reason, we find, in the Merovingian period, papyrus made up into pages to form books, but frequently intercalated with a leaf of parchment between the *gatherings* to give solidity and consistence to the work. After the collapse of the Egyptian papyrus factories Sicily continued to manufacture the material for papal use; but this product was of inferior quality as is seen in examining the last papal bulls on this material. Very many ancient volumina of papyrus have been brought to light in modern times; no less than 150 rolls were found in a chest in the ruins of Herculaneum in 1754; they are so badly charred as to be, for the most part, too brittle to allow unrolling. The Grecian papyri found in Egypt (a great number at Arsinoë, capital of Fayoum) are, in large numbers, in the museums of Vienna, London, Berlin, Paris, Petrograd, Cairo, etc. The largest known papyrus roll is that found in 1855 behind Modinet Habu, on the Nile. It is in the British Museum and facsimiles with translations were published by the trustees in 1876. The volumina are of greatly varying lengths; the Harris papyrus measures over 131 feet and is in London; the medical papyrus of Ebers, in Leipzig, is over 65 feet. The rolls are found inscribed in Egyptian, Greek, Latin, Arabic, Hebrew and Syrian. See PAPER; VOLUMEN; PARCHMENT, etc.

CLEMENT W. COUMBE.

PARÁ, pã-rã', **GRAN PARÁ**, or **GRÃO PARÁ**, grown pã-rã', maritime state of the Brazilian Confederation, lying on either side of the Amazon, bounded on the north by the Guianas (except Brazilian Guiana, a part of Pará) and the Atlantic, on the east by the Atlantic and the states of Goyaz and Maranhão, on the south by Matto Grosso and on the west

by Amazonas. Its area is 443,903 square miles. It has mountain ranges and plateaus on its interior boundaries, but its most striking physical characteristic is its great alluvial plain traversed by the lower waters of the Amazon and Tocantins systems, so that the state is unusually fertile and has remarkable facilities for commerce and transportation. There are settlements on nearly all the rivers: San Jose on the Jary, Almeirin on the Paru, Cametá on the Tocantins, Souzel, Porto de Moz and Villarinho on the Xingu, Santarem on the Tapajoz, Obidos on the Trombetas, Macapá on the mouth of the Amazon and Pará or Belem on the Pará. The india rubber trade, which is now valued at \$35,000,000 a year, is building up towns in the interior away from the rivers. Cacao, vanilla, sarsaparilla, coffee, sugar, hides, copaiba and Brazil nuts are the other leading products and exports of the state, which probably has large mineral wealth awaiting capital. The climate is equable and comparatively healthful in spite of the floods along the river courses. The only railroad is from the capital, Pará (q.v.), to the coast. Pop. about 568,000.

PARÁ (originally SANTA MARIA DE BELEM, that is, Saint Mary of Bethlehem; and hence called BELEM, the present official name), Brazil, capital city of the state of Pará, lying north-east of Rio Janeiro on the Rio de Pará, south of the island of Marajo, 55 miles from the Atlantic. It is connected with Bragança on the coast nearly 80 miles distant by a railway, and is an important port, the only one of the state; it has regular steamboat connections with Brazilian, European and North American ports, and is the seat of a United States consul. An episcopal city, it has a cathedral built in 1720, when the city was in its 106th year, a government palace, a library, lyceum, theatre, botanical garden, two seminaries, electric street railroads, electricity and gas lighting. There are several banks. Pará is the greatest rubber shipping port in the world; of approximate annual exports of \$39,000,000, \$35,000,000 are for rubber. Cacao, Brazil nuts and hides are among the other exports. Imports are valued at \$16,000,000. The city is cosmopolitan, and most of the whites are Portuguese. Pop. 200,000.

PARÁ, Rio de, arm of the sea, forming the embouchure of the Tocantins River on the northeast coast of Brazil, near the mouth of the Amazon, from which it is separated by Marajo Island. The island's southwestern boundary, the Paran, carries some of the water of the Amazon to the Pará. The two rivers were no doubt formerly connected even more closely. The Pará is 138 miles long, 20 miles wide opposite the city of Pará and 40 miles wide at the mouth. It gives its name (which originally meant "river," and occurs in so many compounds, for example, Paraguay, Parana, Paranan, Parananagua) to the state and city of Pará.

PARA, a Turkish and Egyptian coin, the 40th part of a piastre, valued at one-fifth of a cent.

PARA, or ASSAI, PALM. See PALMS.

PARABLE, a fictitious narrative, usually brief, intended to illustrate some point in moral or religious teaching. As used by the ancient

Greeks it meant any literary illustration. The parable is, therefore, of the class of fictitious narratives of which the simile, myth, fable and allegory are other examples. (See SPEECH, FIGURES OF). In the Bible the parable is frequently used to illustrate the teacher's meaning. The descriptions in the Biblical parable keep well within the limits of natural probability and always has for object some spiritual motive with a scope limited to inculcating a single lesson. The parables of Jesus were uttered to illustrate religious truth and in some instances to veil it, as in the parable of the sower (Matt. xiii, 8-23), in which the responsibility of apprehending and applying the lesson is thrown upon the auditor. The word *parable* occurs 48 times in the Four Gospels and but twice elsewhere in the New Testament. Commentators have essayed the classification of the Bible parables into theoretical, parables of grace, prophetic or judicial, etc. Consult Bruce, A. B., 'The Parabolic Teaching of Christ' (4th ed., New York 1911); Dods, M., 'Parables of Our Lord' (2 vols., ib. 1912); Lithgow, R. M., 'Parabolic Gospel' (ib. 1914); Guthrie, T., 'The Parables' (London 1866); Trench, R. C. T., 'Notes on the Parables of Our Lord' (New York 1882); Winterbotham, 'The Kingdom of Heaven' (ib. 1898).

PARABOLA, in mathematics, a plane curve and that one of the conic sections obtained by cutting the surface of a cone with a circular base by a plane parallel to one of the elements. Its characteristic property is that every point therein is equidistant from a given point called the focus, and a given straight line called the directrix.

Construction by Points.—(See Fig. 2). Let F be the focus and the line DN the directrix, and draw FD perpendicular to the directrix. The point A, midway between F and D, will be on the curve, by definition, and is called the vertex. Take any distance $DM > DA$, draw PMP' perpendicular to DF, and, with F as a centre and DM as a radius, describe an arc. This arc will intersect PMP' in two points, P and P', which will give two points on the parabola. Proof: $FP = DM = PN$. P is on the parabola by definition.

Construction by Continuous Motion (See Fig. 2).—Fasten a string at S, one end of a right triangle, and the other end at F, making the length $SPF = SN$. With the triangle in any position, with the short side against a straight edge on DN, bring the string taut against the triangle with a pencil point at P. Move the triangle along the straight edge, that is, along the directrix, keeping the string taut and the pencil-point against the moving triangle. The pencil will trace the parabola, since in every position $PF = PN$.

History.—The parabola is, with the exception of the circle, the oldest of the historic curves, tradition ascribing its discovery to the Greek mathematician Menæchmus (350-330 B.C.), as incident to an attempt to solve the problem of the two mean proportionals, to which the famous Delian problem of the duplication of the cube has been reduced by Hippocrates of Chios. The object of this problem is to find two quantities, x and y , such that $a : x = x : y = y : b$, which requires that the equations $x^2 = ay$ and $y^2 = bx$ shall be satisfied simul-

sects the parabola $y^2 = 4px$ in general in two points, determined by $x = \frac{1}{m^2}(bm - 2p) \pm 2\sqrt{\frac{p}{m^2} - b^2pm}$. These become coincident when $b = \frac{p}{m}$, affording as the equation of the tangent in terms of its slope, (4) $y = mx + \frac{p}{m}$. By

transformation of co-ordinates, the equation of the parabola referred to any diameter and the tangent as its extremity may be shown to retain

FIG. 2.

the normal form (5) $y'^2 = 4px'$, and it follows that (3) will also retain the same form. By assuming y or y' , as the case may be, equal to zero we find the x intercept of the tangent equal to x or x' , that is, the sub-tangent is bisected at the vertex.

To Construct a Tangent.—By virtue of the foregoing property, when the point is on the curve, construct the ordinate of the point and lay off the length of the abscissa to the left of the vertex. Connect this point on the diameter with the point on the curve. If the point is outside the curve, draw the diameter of the curve through the point, lay off the distance measured on this diameter from the point to the curve to the right of the temporary vertex, and draw the chord through the point thus determined parallel to the tangent at the temporary vertex. The line through the points in which this chord cuts the curve and the given point will be the required tangents.

The Normal.—Since the normal is the perpendicular to the tangent at the point of tangency, its equation becomes (6) $y - y_1 = -\frac{y_1}{2p}(x - x_2)$, which cuts the axis at the point $2p + x_1$.

The Subnormal is, therefore, constant and equal to $2p$. This property enables us to construct the directrix and the focus by laying off p to the left and to the right of the vertex, p being obtained by bisecting the subnormal. The focal radius $FP = FN = x_1 + p$, whence the angle $FNP =$ the angle NPL ; that is, the normal bisects the angle between the focal radius and the diameter through any point. This prop-

erty causes rays of light at the focus to be reflected in parallel rays and is made use of in parabolic reflectors. The two tangents $y = mx + \frac{p}{m}$ and $y = -x - pm$ are perpendicular and intersect at the point whose abscissa is p ; that is, perpendicular tangents intersect on the directrix.

The Latus Rectum is the double ordinate through the focus and is equal to $4p$. The tangents constructed at the extremities of the latus rectum intersect on the directrix, and are, therefore, at right angles. The area of the parabola included between any chord and the curve is given by the formula

$$\begin{aligned} \text{area} &= 2 \sin \theta \int_0^{x'} y' dx' = \\ 2\sqrt{2p} \sin \theta \int_0^{x'} x'^{\frac{1}{2}} dx' &= \frac{4}{3} \sin \theta \cdot \frac{1}{2} x'^{\frac{3}{2}} = \\ \frac{4}{3} &\text{ of the area of the parallelogram constructed} \\ &\text{with the chord and } x' \text{ as its sides.} \end{aligned}$$

Rectification of Parabola.—The length of a parabolic arc is obtained as follows (see CALCULUS):

$$\begin{aligned} S &= \int \left[1 + \left(\frac{dx}{dy} \right)^2 \right]^{\frac{1}{2}} dy = \frac{1}{2} y \sqrt{y^2 + p^2} + \\ &\frac{p}{2} \log (y + \sqrt{y^2 + p^2}) + C. \end{aligned}$$

If the arc begins at the vertex, then $s=0$ when

$$\begin{aligned} y=0 \text{ or } 0 &= -\log p + c_1 \text{ whence} \\ S &= \frac{1}{2p} y \sqrt{y^2 + p^2} + \frac{p}{2} \log \frac{y + \sqrt{y^2 + p^2}}{p}. \end{aligned}$$

Radius of Curvature.—The radius of curvature of the parabola at the point (x, y) is given by the formula

$$R = \pm \frac{\left[1 - \left(\frac{dy}{dx} \right)^2 \right]^{\frac{3}{2}}}{\frac{d^2y}{dx^2}} = \pm \frac{\left(1 + \frac{p^2}{y^2} \right)^{\frac{3}{2}}}{\frac{p^2}{y^2}} = \pm \frac{(p^2 + y^2)^{\frac{3}{2}}}{p^2}$$

J. BRACE CHITTENDEN, Ph.D.

PARABOLANI, men whose duty in the early Church was to attend on the sick and diseased. The term was originally applied to gladiators, and is derived from the Greek *parabolos*, reckless, in allusion to the courage with which these laymen nursed those who suffered from infectious diseases. Such functionaries were attached to all the principal churches of the East, and at Alexandria they formed a corps of 500 men. Theodosius the younger increased this number to 600, because plagues and contagious diseases were common in Egypt. This emperor placed them under the jurisdiction of the chief magistrate, but they were appointed by the bishop, whose directions they were bound to follow. As the parabolani were

bold and indifferent to death, laws were enacted to prevent them from exciting seditions which were particularly common at Alexandria. Their number was limited by Theodosius, and they were forbidden to attend at public assemblies and courts of justice, unless they had some business there sanctioned by the law. More than once they showed themselves deserving of suspicion, as for example at the Council of Ephesus in 449, when a Syrian monk named Barsumas, at the head of a band of armed parabolani, committed outrageous excesses and terrified the council into granting his demands.

PARABOLOID, in geometry, a solid figure traced out by a parabola revolving round its principal axis. It is a characteristic property of paraboloids that they have no centres except in the extreme cases, when they have an infinite number of centres. There are three varieties of paraboloids, elliptical, hyperbolic and parabolic.

PARACATU, pã-rã-kã-too', Brazil, town in the eastern part of the state of Minas Geraes, 450 miles northwest of Rio Janeiro, on the river of the same name, which is an affluent of the São Francisco. The city dates from the middle of the 18th century, in which it was the centre of a rich auriferous district. The gold-washings are no longer of value; cattle, hides, sugar-cane and coffee are its important products. Pop. about 15,000.

PARACELSUS, pãr-ã-sel'sūs (PHILIPPUS AUREOLUS THEOPHRASTUS BOMBASTUS VON HOHENHEIM), Swiss physician, chemist, and charlatan: b. Maria-Einsiedeln, Canton Schwyz, 17 Dec. 1493; d. Salzburg, 23 Sept. 1541. He acquired considerable real knowledge of medicine and chemistry, but spent his time in searching for a universal specific and the philosopher's stone. In his wide travels, extended to the East, he derived, in addition to the arts of alchemy and magic, a knowledge of certain remedies not then familiar to Continental physicians, and by this means effected numerous cures which brought him high prestige. In 1526 he became professor of medicine in the University of Basel, and there he burned publicly the works of Avicenna and Galen and declared himself the monarch of physic. He drew about him a school known as the Paracelsists, and claimed among his discoveries that of indefinitely prolonging life. In 1528, owing to a quarrel with the magistracy, he left Basel for a wandering existence in Switzerland, Alsace and southern Germany. His methods of puffing long prevented a just estimate of him; but he is now seen to have enriched medicine and chemistry, and especially to have made great contributions to, if not to have founded, modern pharmaceuticals. A complete edition of his works (Latin) appeared at Basel in 1589. Consult the 'Life' by Hartmann (1887).

PARACHUTE, a mechanism of an umbrella shape, about 20 or 30 feet in diameter, attached to balloons, by means of which the aeronaut may descend slowly from a great height. It has a hole at the top to prevent oscillation. In 1783 the French physician Lenormand made several experiments with parachutes of 30 inches in diameter at Montpelier; and shortly after the machine (enlarged

to something like its present dimensions) became well known through the public descents of Blanchard in Paris and London. Garnerin was the first to suggest their use for balloonists in case of accident. See BALLOON.

PARACLETE (*parakletos*, a counselor; encourager, admonisher or comforter), in the English translation of the Bible, the Comforter, the Holy Ghost. Jesus promised to his disciples (John xiv, 16) that his Father would send them another Comforter, the Spirit of Truth, who would abide with them forever, teach them all things (ver. 26), and bring all his sayings to their remembrance. It is also the name of a monastery near Troyes which Abelard founded and where he was buried.

PARADIN, a vegetable poison. See HERB PARIS.

PARADISE, the garden of Eden. The word is originally Persian and signifies a park. It has been introduced into modern languages as a name for the garden of Eden (see EDEN) and hence of any abode of happiness. In general, the heavenly abode of the blest. Numerous scripture passages refer to Paradise as the equivalent of heaven, a place where those who die in the Lord shall dwell with him forever. No very definite conclusion can be drawn by considering the very numerous Bible references, but Milton typified the popular idea in his 'Paradise Lost' (q.v.). Some sects undertake to dogmatize concerning Paradise as the place where the souls of the righteous await the final resurrection and entry into heaven. But science recognizes neither Paradise nor heaven. The Mohammedan idea of Paradise is that of a beautiful watered area—the opposite of a desert—inhabited by celestial beings of both sexes, who take their fill of sensual delights. The Puritanical idea seems to have been a place where saints and angels mingle and spend most of their time playing harps and singing the praises of the Deity. All sorts of conceptions between these two have been advanced, and many learned theologians have written voluminously on the topic, but without adding to the sum of the world's knowledge of life beyond the grave. According to the accounts in Genesis II, Exodus III, Numbers XIII, Paradise was a place of mountains, with four rivers flowing with milk and honey. Some texts indicate an earthly location, as those in Genesis, but generally it appears as a heavenly region. Consult Salmond, 'The Christian Doctrine of Immortality' (1895); Sharman, H. B., 'Teaching of Jesus About the Future' (1909); Dobschutz, E. A., 'Eschatology of the Gospels' (1910).

PARADISE-BIRD. See BIRDS OF PARADISE.

PARADISE FISH, or **FISH OF PARADISE**, small Oriental fish (*Polyacanthus viridicaudatus*) allied to the climbing-perch (*Anabas*), which belongs naturally in the fresh-water streams, and is extensively bred in aquariums by the Chinese, on account of its brilliant coloring. Fantastic varieties, with greatly extended and modified fins and tail, have been developed.

PARADISE LOST, a blank verse epic in 12 books, was composed by John Milton in blindness between the years 1658 and 1665 and published in 1667. Originally conceived, in dra-

matic form, as early as 1640, it is the fruit of the study and meditation of a lifetime, the fulfilment of Milton's long-cherished ambition to write a poem which after times would not willingly let die. In 'Paradise Lost' the religious and moral ideals of Puritanism receive their most permanent expression, but the poem embodies also the broad and humane culture, the sense of poetic beauty and the imaginative fervor of the English Renaissance. Though the subject was one which had been often treated, Milton owed little to any specific work on the fall of man, the Bible and the Greek and Latin classics being the chief sources of his literary inspiration.

In Milton's mind the theme of 'Paradise Lost' was the worthiest that poet ever had. To him the fall of Adam was not only a literal fact; it was the most momentous event in history, involving as it did the destinies of all mankind. The subject was one which gave full scope for the sublime poetic genius of which he felt himself to be possessed. He ranges beyond the immediate story of the fall to the causes of that event in the revolt of Lucifer and to its consequences in the sufferings of man and his ultimate salvation through the sacrifice of Christ. The action moves in illimitable space: from the glittering plains of heaven we descend to the abyss of hell, and we wing our way with Satan up through chaos to the newly-created universe, which hangs by a chain from the celestial battlement and of which, according to the Ptolemaic astronomy which Milton uses, the centre is our earth. Nor are the personages involved in the epic narrative less tremendous.

The poem begins with a marvelous description of Satan and the mighty spirits who fell with him rolling stunned and agonized on the burning lake of hell, whither they have been driven by the hosts of heaven. Though blasted and overwhelmed by almighty power their spirit is undaunted. In Satan, Milton has portrayed for all time the type of the rebellious soul. He is no vulgar devil, but an archangel ruined, the worthy antagonist of God and man, cursed with the sin of pride, but commanding admiration for his unconquerable purpose, his indomitable courage, and his superb powers of leadership. The two first books, which deal with the plot in hell to injure the Almighty by ruining his creature man, represent, by general agreement, the loftiest heights of Milton's imagination. The third, in which the fate of man is discussed in heaven and the sacrifice of Christ proposed, is theological and on the whole less interesting. In the fourth the scene and tone of the poem entirely change. We behold the newly-created Adam and Eve amid the beauties of an idyllic paradise. Satan learns that God has forbidden them to eat the apple of the tree of life and resolves to make his assault on the weaker Eve. But God, lest man should be left to fall in ignorance, sends Raphael to tell him the story of the revolt in heaven, to reiterate the prohibitory warning and to apprise him of the nearness of the enemy. In this way the narrative is rounded out after the fashion of the ancient epics, and many matters relating to the construction of the universe and position of Adam and Eve explained. Our first parents are also allowed to tell, with

engaging naïveté, the story of their first experiences on earth. The stage is now set for the final struggle. Through a clever trick and by appealing strongly to her vanity Satan induces Eve to eat the apple. Adam, fully conscious of the tragic consequences impending, but allowing his passionate love to sway his judgment, resolves to share her fate. The rest of the poem is devoted to a portrayal of the effects of the fall. Evil has broken in and Paradise is shattered. The agony of a sinful conscience afflicts the unhappy pair. They cower before the stern mandate of exile and the more mysterious and terrible fate of death which is foretold. Yet at length they seek reconciliation with God, and he, in accordance with his plan of mercy, sends Michael not only to unroll before Adam's eyes in vision the pageant of humanity suffering and sinning for his sin, but also to prophesy salvation through Christ and to hold out the promise that Adam may, through self-conquest, win in time an inward paradise, far happier than the Eden he has lost. The poem thus contains within itself the wider motive of 'Paradise Regained,' but true to the title and to the specific theme, Milton returns at the end to the picture of the exile and the note with which he closes is one of merely tempered sadness.

"They, hand in hand, with wandering steps and slow
Through Eden took their solitary way."

The greatness of 'Paradise Lost' lies primarily in the imaginative grandeur with which Milton conceives and depicts the scenes and characters of his cosmic story and in the majestic utterance which makes his verse the supreme example of the "grand style" in English literature. To read and enjoy Milton is to dwell for a time on the high places of thought and feeling, to respond to a trumpet call to rise up in heart and embrace a world of superhuman magnitude as seen through the medium of a pure and lofty spirit. For it was a fundamental principle of Milton's creed that he who would write well of laudable things, "ought himself to be a true poem," and the quality which underlies the greatness of 'Paradise Lost' is the moral and spiritual beauty of Milton's nature, that loftiness of spirit which prompted Wordsworth to say of him:

"His soul was like a star and dwelt apart."

Many critical problems have arisen in connection with this poem. The most important discussions have concerned themselves with the theme and the hero. Technically Milton is writing, as he says, of the fall of man as a historical event and a theological fact. But even to those who reject the Calvinistic beliefs upon which 'Paradise Lost' is based there remain in the poem the fundamental human experiences of rebellious pride, of energy perverted to an evil purpose, of temptation, sin, repentance, reconciliation to the will of God; and these Milton has handled with profound insight and abiding truth. The question of the consistency or inconsistency of Milton's thought need not trouble the modern reader. We do not ask from a poet a new theological system, but a concrete and imaginative embodiment of accepted beliefs and a grasp of the fundamental human reality which they contain. It is true that Milton's God is unsatisfactory even on

poetic grounds, that the endeavor to express immaterial reality in terms of time and space often results in gross absurdity. But such limitations, imposed on Milton by the nature of his subject, are amply compensated for by the power and beauty which abound in the accounts of Satan, Adam and Eve, by the vividness and energy of both the grand and the idyllic scenes, by the moral fervor which pervades the poem, and by the skill with which the narrative as a whole is handled. To say, as one must say, that the hero is Adam, is not to deny that Satan is the most interesting figure or that Milton was led by his own experience as a rebel against constituted authority to enoble his resistance until it wins from the reader an undue measure of sympathy. What Milton never does is to forget for a moment that Satan is a perverted being. His ultimate frustration illustrates the power of God, with the co-operation of man's righteous will, to make evil itself the instrument of good.

The fame of 'Paradise Lost' has endured, despite the changes of thought and taste, through all ages since Milton's own. Notwithstanding the attacks leveled at it by men like Taine and Scherer its claim to hold rank among the masterpieces of world literature has never seriously been questioned. Its influence on poetry has been enormous. As an intellectual and imaginative heritage of the English speaking peoples it is second only to the King James version of the Bible and to the plays of Shakespeare.

Editions: 'Poetical Works' (ed. by David Masson; 3 vols., 1874, ff.); 'Poetical Works' (1879); Raleigh, W. A., 'Milton' (1900); 'Paradise Lost' (ed. by A. W. Verity, 1892-95); *Criticism:* Addison in *The Spectator*, 31 Dec. 1711-3 May 1712; Mark Pattison, 'Milton' (1879); Raleigh, W. A., 'Milton' (1900); Trent, W. P., 'John Milton' (1899). A list of the numerous books and special articles dealing with 'Paradise Lost' will be found in E. N. S. Thompson's 'Topical Bibliography of John Milton.' Consult also 'Cambridge History of English Literature' (Vol. VII, pp. 469-479).

JAMES H. HANFORD,

Associate Professor of English, University of North Carolina.

PARADISE REGAINED. 'Paradise Regained,' a blank verse epic in four books, was undertaken by its author, John Milton, as a sequel to 'Paradise Lost' at the suggestion of the Quaker, Thomas Ellwood. Though composed perhaps as early as 1666 it did not appear until 1671. It is characteristic of the Puritan, to whom life presented itself as a moral struggle, that Milton should have chosen as his theme not the crucifixion but the temptation of Christ. The poem is thus more truly the complement of 'Paradise Lost.' As Adam fell from his happy state through failure to resist temptation by Satan so Christ regained Paradise for man by proving victorious in a similar trial.

Milton has taken as his basis the scriptural account of the temptation in the wilderness. The first of the three crises—the temptation to satisfy physical hunger by turning the stones to bread—is treated simply. The second—the offer of the kingdoms of the earth—is elaborated by dialogue and description until it constitutes the greater part of the poem. Satan, frustrated,

in his first attempt, spreads before the eyes of Christ a royal banquet, representative of the power of wealth in its lowest physical form. When this is rejected he offers glory, then empire with a subtle show of furthering Christ's work. Milton here seizes the opportunity to depict with majestic sweep of language the varied pageant of the nations—the barbaric magnificence of the East, the splendors of imperial Rome, and finally, as a climax, the nobler intellectual glories of classic Greece. When Christ has answered all the tempter's sophistries with penetrating insight and has resisted even the lure of ancient wisdom as a means of furthering his ministry on earth, Satan, confuted and desperate, catches him up to the pinnacle of the temple and bids him stand upright in his uneasy station or cast himself down, "safely if Son of God." With Christ's reply "also it is written, Tempt not the Lord thy God," the triumph is complete.

"He said and stood,
But Satan smitten with amazement fell."

Ministering angels bear the Saviour down to a flowery valley and heavenly choirs sing anthems of the victory "over temptation and the Tempter proud" whereby he has potentially

"regained lost paradise.
And frustrated the conquest fraudulent."

'Paradise Regained' lacks the brilliancy and color of 'Paradise Lost' and has never claimed the same interest and enthusiasm from multitudes of readers. It is the work of a man to whom the interests of the world meant little in comparison with religious truth and the welfare of the soul. Yet the greatness of Milton's genius is nowhere more apparent. In the highly concentrated action two great forces stand face to face. The Satan of 'Paradise Regained' is a meaner figure than he "who durst defy the Omnipotent to Arms," but he possesses an even greater subtlety of intellect. The Saviour is a Godlike man, divinely calm and strong. The contest between the two is more significant because it takes place not in the physical arena but within the soul. As a harmonious work of art 'Paradise Regained' has even been held by some critics to be superior to 'Paradise Lost.' Consult the works on Milton listed under 'Paradise Lost' and also Gilbert, A. H., 'The Temptation in Paradise Regained' (*Journal of English and German Philology*, Vol. XV).

JAMES H. HANFORD.

PARADOX, that which runs counter to general idea and expectation, and appears accordingly to be incredible and incomprehensible, especially in literature or science. The word means literally "contrary to opinion," but it has been extended and is now generally employed to describe that which is manifestly or apparently contradictory on its face, hence absurd, as a statement to the effect that a man is heavier after cutting off a leg.

PARADOXIDES, a fossil trilobite of the Cambrian series of North America and Europe. See **TRILOBITES**.

PARADOXURE, a civet of the Oriental genus *Paradoxurus*, of which there are 10 or a dozen species popularly called palm-civets (q.v.). The tail is not prehensile but may be curiously coiled.

PARAFFIN (Latin, *parum affinis*, without affinity), a white, waxlike substance, solid at ordinary temperatures, which may be obtained by the distillation of carbonaceous materials, or of oily or coal-bearing shales. Crude petroleum oil is now the chief source of the commercial supply of paraffin. The oil is subjected to a process of fractional distillation, by which naphtha, kerosene, light mineral oil and heavy mineral oil are successively obtained. The distillation is usually carried on until further application of heat would be likely to cause carbonization; and the paraffin is then left in the heaviest, least volatile portions. When the process is correctly conducted, the paraffin crystallizes out when the heaviest oil is allowed to stand in the cold; and it is afterward purified by washing with benzine and by such further treatment as may be required. Paraffin is somewhat lighter than water, is insoluble in nearly all of the ordinary solvents and is not affected readily by acids or alkalis. It is not a definite chemical substance, but consists of a mixture of hydrocarbons in varying proportions—chiefly of those designated as “paraffins” (q.v.). It melts readily and without decomposition, but its melting point varies with its composition and may range from 120° F. to about 200° F. It is greatly used for making candles, either alone or when mixed with a small proportion of stearin. It is also used in quantity for coating acid tanks, for waterproofing paper and other fabrics, for producing a high gloss in fine laundry work, and is an excellent electrical insulator, being used for impregnating the cotton coverings of electrical conductors, rendering the cotton impervious to moisture. The method of waterproofing paper with paraffin is interesting. A roll of paper is led through a trough of melted paraffin and then passed between rollers to preserve an even surface. Sometimes a knife or scraper contacts the wrong side of the paper, on which little or no paraffin is desired. Paraffin is often called “paraffin wax.” See PARAFFINS.

PARAFFINS, in chemistry, the series of hydrocarbons that have the general formula $C_n H_{2n+2}$. They are all distinguished by a marked chemical inertness and derive their name from this circumstance. (Compare PARAFFIN.) The paraffins occur in nature in petroleum oil and they are also obtained by the destructive distillation of coal, peat, carbonaceous shale and numerous other substances. They may be roughly separated, from petroleum, by fractional distillation; but their exact separation, when mixed in such a general manner, is attended by the greatest difficulty. Many of them may be prepared, however, by heating the iodides of the alcoholic radicals with metallic zinc. Ethane (C_2H_6), for example, may be obtained by treating metallic zinc with iodide of methyl, CH_3I ; the reaction in this case being $Zn + 2CH_3I = C_2H_6 + ZnI_2$. The best known of the paraffins are as follows, the temperatures opposite them being their boiling points:

Methane.....	CH_4	(Gaseous)
Ethane.....	C_2H_6	“
Propane.....	C_3H_8	“
Butane.....	C_4H_{10}	34° F.
Pentane.....	C_5H_{12}	100°
Hexane.....	C_6H_{14}	158° F.
Heptane.....	C_7H_{16}	210°
Octane.....	C_8H_{18}	255°
Dodecane.....	$C_{12}H_{26}$	396°
Heedecane.....	$C_{16}H_{34}$	532°

The paraffins belong to the fatty series of hydrocarbons (see FATTY COMPOUNDS), and their constitutional formulæ, therefore, consist entirely of open chains, though these chains may be branched, as will presently appear. The formula for propane, for example, may be written $CH_3-CH_2-CH_3$. Any one of the paraffins may be regarded, from a structural point of view, as derived from the preceding number of the series by substituting the radical methyl (CH_3) for a hydrogen atom. Thus if one of the hydrogen atoms in the right-hand methyl group of the foregoing formula for propane be itself replaced by CH_3 , we shall have the new compound $CH_3-CH_2-CH_2-CH_3$, which is butane. A paraffin which contains only two methyl radicals is said to be a “normal paraffin”; and in the table of boiling points given above, the corresponding paraffins are all supposed to be “normal.” Methane, ethane and propane are not capable of existing in any but the “normal” form; but the higher paraffins may also exist in isomeric forms. In introducing the methyl radical in propane, for example, we replaced one of the hydrogen atoms in the right-hand CH_3 group; but we might equally well have replaced one of those in the central CH_2 group, and in that case the resulting compound would have had the structural formula

and while this compound still has the empirical formula C_4H_{10} , and is still known as “butane,” there is obviously no reason for supposing that it would have the same physical and chemical properties as the butane which contains only two methyl groups. There are, in fact, two butanes known. One of these (“normal butane”) boils at 34° F., has a specific gravity of 0.600, and may be prepared by the action of zinc upon ethyl iodide at 300° F. The other (known as “iso-butane,” “trimethyl-methane” or “secondary butane”) boils at about 3° F. and may be prepared by heating aluminum chloride with iso-butyl iodide; the iso-butyl iodide being prepared by the action of hydriodic acid upon iso-butyl alcohol, which, in turn, is obtained by the fermentive action of “*Bacillus butylicus*” upon sugar or glycerine. The higher members of the paraffin series admit of an increasingly great number of isomeric modifications, many of which have not yet been studied, nor even prepared. Dodecane, for example, may exist in as many as 355 different isomeric modifications.

PARAGUA, pā-rā'gwā, Philippines, a province including the part of the island of Palawan that lies north of the 10th parallel of latitude, the Calamianes Islands (q.v.) and the Cuyo Islands (q.v.); area of the mainland, 1,366 square miles, with the dependent islands, 1,635 square miles. The mainland of Paragua is mountainous, the central mountain range of Palawan extending from northeast to southwest; the rivers are numerous but short, as in the rest of the island. The staple crops are tobacco, rice, sugar and vegetables, but nothing is raised for export; the forests are valuable and extensive; and gold, lead and other minerals are found. The most important industries are stock-raising and the gathering of edible birds' nests. Cowries are also gathered in the

islands and exported. The only mechanical industry is the weaving of textiles for home use. Civil government was established in this province in 1902 and the capital located at Cuyo, island of Cuyo. Pop. of the entire province, 49,850; of the mainland, 25,000.

PARAGUARI, pā-rā-kwā-rē', Paraguay, department and capital city of the department in southern Paraguay. The city, 35 miles southeast of Asunción, is situated on an eminence overlooking a tributary of Lake Ipoa, and is on the railroad between Asunción and Encarnación. There is much trade in tobacco from Villa Rica and the surrounding country. The city, founded in 1775, was the scene in 1811 of a victory over an invading army from Argentina. Its growth has been remarkable. Pop. 10,000.

PARAGUAY. A country of South America, enclosed between Brazil, Argentina and Bolivia. Estimates of the total area range between 122,000 square miles and 196,000 square miles. The chairman of the delegation of Paraguay to the first Pan-American Financial Conference estimated the superficial area at 445,000 square kilometers; the Pan-American Union handbooks give 507,640 square kilometers, or 196,000 square miles.

National Boundaries, etc.—The country is divided into two sections by the Paraguay River, the eastern section being called El Paraguay Oriental and the western El Gran Chaco or El Paraguay Occidental. On the north it is bounded by Bolivia and Brazil; on the east and southeast by Brazil and Argentina; on the south and west by Argentina.

A consequence of the government's efforts to encourage immigration and colonization is seen in the establishment of the following colonies: Villa Hayes Colony, nearly opposite Asunción in El Gran Chaco, settled by families from Switzerland, France, Italy, Belgium, Germany, Austria and Spain; San Bernardino Colony, settled principally by Germans; Colonia Nacional, on the railway from the capital to Villa Encarnación; Nueva Alemania Colony, in the department of San Pedro; Elise, or San Antonia Colony, in the department of San Lorenzo de la Frontera; Nueva Australia Colony, containing Australians, English and Paraguayans; Colonia Cosme, in the department of Caazapa, also inhabited by Australians; Colonia Guillermo Tell, a Swiss settlement; and the Hohenau Colony, a small community of German, Brazilian and Paraguayan coffee planters.

Topography and Hydrography.—The general level of the Chaco and the lowlands of the western part of El Paraguay Oriental is approximately 250 or 300 feet above that of the sea; the eastern side of Paraguay is, however, much higher, with the exception of the extreme southeast, which is a low-lying, swampy region. An extension of the plateau or highlands of Brazil is seen in the northeast, the so-called Sierra of Amambay, with lateral spurs running toward the Paraguay River. Through the centre of the country, from Villa Encarnación toward the northeast, run the cordillera of Villa Rica and the Caaguazú Mountains; and a transverse range, crossing the Paraná River into Brazil, forms the great cataract of Guayrá. These ranges have an elevation above sea-level of 1,500 to 2,000 feet. The position of Paraguay Oriental has been aptly compared with

that of the State of Illinois, for its southern boundary is at the confluence of two great rivers, and more than 800 miles above Buenos Aires and the La Plata estuary. Of these rivers, one, the Paraguay, forms the western boundary below Asunción, while, above the capital, it passes between the eastern and western divisions of the republic, as already stated; the other, the Paraná, separates Paraguay from the Argentine republic and Brazil on the south and southeast. A large part of the territory lying between these great streams is not yet well known. The Pilcomayo River, flowing south-eastward from Bolivia, forming the southern boundary of Gran Chaco, and joining the Paraguay below Asunción, is navigable for a distance of 150 miles from its mouth. The Paraná flows 1,367 miles from its source in Goyaz, Brazil, before uniting with the Paraguay; the latter is about 1,800 miles long; both have large tributaries in Paraguay Oriental.

Mineral Resources and Soils.—The northern part of Paraguay is covered with limestone, while the southern is of sandstone formation. Marble is reported as abundant in the north, iron in the south. Several veins of copper have been found. Other minerals, according to semi-official statements, are kaolin (in the departments of Caápuć, Ibicui, Quiglio, Villa Rica, Cordillera, Villeta and Luque); talc; graphite; serpentine stone; basalt (near Villa Encarnación); manganese in several deposits that are thought to be extensive. There are four distinct varieties of soil, namely, (1) sandy, either white or red, the latter being fertile; (2) a good argicultural soil, consisting of clay and quartz, oxide of iron, lime and miscellaneous substances; (3) humus, characteristic of forest lands; and (4) the black alluvial deposits, prevailing in western Paraguay.

Climate.—Paraguay is regarded as a sanitarium by the inhabitants of some of the neighboring countries; and it is quite true that the capital and its suburbs are moderately healthful. The mean temperature at Asunción is about the same as that of Cairo, Egypt; Hongkong, China; and Caracas, Venezuela, while the mountainous interior regions are decidedly cooler. Rain is abundant throughout the year; snow is entirely unknown; storms, with accompanying high winds and very severe thunder and lightning, occur frequently.

Flora and Fauna.—Eastern Paraguay is covered with virgin forests of great lianas, pindo and embocaya palms, orange and banana trees, timbo brush, interspersed with great grasses and flowering plants. West of the Paraguay lies the Chaco region, covered largely with marshes, heaths and yatái palms. Quebracho forests occupy the higher regions. The jaguar is the most formidable denizen of the wild, but there are also the puma, tiger cat, marten, tapir, polecat, peccary and deer. There are large alligators and many venomous snakes. Boas reach a great size, but are very inoffensive. Paraguay is famed for its birds. Flies and gnats are veritable pests in the wild regions, but apparently disappear with the clearing and cultivation of the land.

Religion and Education.—Article III (Pt. I, Chap. I) of the constitution provides: "The religion of the state is the Roman Catholic Apostolic; Congress, however, shall not have

the power to forbid the exercise of any other religion within the territory of the republic. The chief prelate of the Paraguayan church shall be a Paraguayan." Article VIII declares: "Primary instruction is compulsory," directing Congress to "promote by all possible means the instruction of the citizens." Professors at the national college are appointed by the President of the republic, though nominated by the council of that institution. The entire educational system was, from 1609 to 1767, entrusted to the Jesuits; the tendency to nationalize it has grown strong principally during the last 40 years. In all schools the Spanish language is taught, and the Guaraní, though still the tongue of the common people everywhere outside of the larger towns, is gradually being displaced; it is even prohibited within the college precincts. The educational system adopted by the government provides for rural schools, with three grades; elementary schools, with four grades; and more complete schools with six grades (consult Report of the Commissioner of Education for the year ended 30 June 1915, Washington 1915). An agricultural school is being established at Ypacarai, with two instructors, who have been educated abroad, in charge of courses of study. The system of employing teachers for special subjects, which prevails in secondary schools throughout South America, is applied to a certain extent in Paraguay's elementary schools.

Industry and Commerce.—*Forest and Agriculture.* Woods which are valuable on account of their extraordinary durability and powers of resistance are characteristic forest products; many of these being so heavy that they sink when thrown into the water. Dye-woods of many varieties, medicinal and resinous trees, wild vanilla, etc., are found. The chief and most distinctive product of the country is yerba, the "Paraguayan tea," also called yerba maté; sugar cane, cotton, tobacco, mandioca, rice, maize, coffee, textile plants (caraguatá, ibira, etc.), oranges, bananas and grapes are successfully cultivated. A memorandum submitted by the delegation of Paraguay to the First Pan-American Financial Conference, held at Washington in 1915, contains the statements that the "artificial cultivation" of yerba maté, tried until recently without good results, has finally been successful, and now extended plantations of it may be seen; that the cultivation of tobacco is being perfected, thanks to the efforts of the Banco Agrícola; that the yield of cotton of fine quality, with long, silky and strong fibre "is proportionately superior to that of any other cotton-raising country"; that sugar cane, rice and Indian corn are cultivated with easily-won success; and that the list of agricultural products, some of them unknown elsewhere, includes mamón, mandioca, tástago (from which castor oil is locally extracted), coffee, wheat, olives, coco, ramie, barley, vanilla, cinnamon, etc. Forests cover about one-half of the total area, and these contain "an incalculable wealth in woods for construction and for cabinetmaking," of which the following are of demonstrated utility: curupay and lapacho, both very durable; incienso, a strong and flexible wood; ibiraró, considered a good substitute for teakwood; cedar and petereby, the latter as well as the former suitable for cabinetmaking; timbó and ibyapytá, both very

abundant, and the latter useful as a material for paving-blocks; laurel, used for railway ties; guayaybí with qualities similar to those of hickory; palo santo, "suitable for axle bearings, in place of metal"; quebracho the axe-breaker, etymologically, and well-known industrially as a source of tannin and as resistant material for railway ties. Among the numerous resources on which the country depends, cattle raising is mentioned as one of the most profitable, pasture-land being abundant, well watered and provided with natural shelter for the animals.

The tobacco industry reached the maximum figures in 1916, the entries in the market amounting to 77,804 bales in the first 11 months of the year, or 13,830 bales more than in the previous year. Only 61,000 bales were exported in the 1916 period, as low water in the river temporarily obstructed exportation. The normal tobacco crop is about 22,500,000 pounds. The livestock industry, which is counted as the chief source of wealth in Paraguay, has been developing recently and is receiving a new impulse under the prospect of the establishment of a packing house by manufacturers from the United States. The exports of live animals to Argentina have not varied greatly in the last four years, the figures being as follows: 1913, 39,564 head; 1914, 24,385; 1915, 29,509; 1916, 29,940. The yerba crop of 1916 amounted to 7,206,227 pounds. Quebracho exports in 1916 reached 21,136 tons. Sugar is produced to the amount of 1,600 tons annually. A census taken of the livestock in Paraguay in 1915 gave the following figures: Horned cattle, 5,249,043; sheep, 600,000; horses, 478,000; mules, 17,000; asses, 18,000; hogs, 61,000 and goats 87,000. Among the cattle countries of South America that have cattle for export, Paraguay is said to occupy second place, with 11.8 head per square kilometer and 5,249 beeves for each 1,000 inhabitants of the country.

Some Characteristic Industrial Products.

—The very moderate activity we have observed in the industrial life of Paraguay is directed chiefly to forest industries, such as the production of tannin at Puerto Casado, Puerto Sastre, Puerto Max, Puerto María, Puerto Galileo, and other places. The preparation of woods for exportation is carried on at the Nogués and Pinasco plants, at Puerto Médanos and many other points that are connected with ports of shipment by private railways. Exploitation of Paraguayan tea (yerba maté) is to a large extent controlled by the organization known as The Industrial Paraguaya.

In the making of the very beautiful ñanduti lace, Paraguayan art and industry unite, contributing equally to a charming product—the artistic tradition being an inheritance from the early days of the Spanish occupation, while the exemplary patient labor in the execution of traditional lace designs is, of course, a characteristic expression of that limited art-impulse of the aborigines which is associated with patient workmanship. Excellent hammocks are made by the same painstaking folk. As meritorious products we mention also the native cigars, the great variety of preserved fruits (native fruits in native cane sugar), and the extract from the leaves of a native orange tree which is known commercially as petitgrain or oil of petitgrain, of which 101,717 pounds were exported in 1916.

Imports and Exports.—The values of foreign commerce for the year 1915 were, for imports \$2,340,510 and for exports \$5,409,858; a total of \$7,750,368 only; for 1916, imports \$4,651,525 and exports \$4,807,460, a total of \$9,458,985, whereas in 1913 the total was \$13,539,744 gold and \$9,441,807 even in 1914, when the effects of the European War were first apparent. Before the war an increase was noted from year to year, and the chief sources of imports were then in Germany, England, Argentina, France, Spain and Italy; the articles imported being textiles, foodstuffs, hardware, fancy goods, wines, spirits, drugs and chemicals, ready-made clothing, chinaware and crockery, hats, rugs and carpets, shoes, jewelry and railway or tramway materials. The principal exports are livestock, wool, dried beef, oranges, tobacco, cocoanut bran, essence of petitgrain, extract of quebracho, yerba maté, palms and many kinds of wood. Commercial interchange with the United States during the years 1910–17 was on a footing of small values for exports from Paraguay—only about one-third as much as the total of Paraguay's imports from the United States during that period. In 1914 Paraguay's exports to the United States were valued at \$10,668, and her imports from the United States at \$413,937; but in 1915 the figures were: Paraguay's exports to the United States valued at \$292,410 and imports from the United States, \$209,148. Imports from the United States in 1916 amounted to \$570,000, and exports to \$228,000. Paraguay's total imports in 1916 were \$4,530,000, and exports \$4,710,000.

Political Divisions, Cities and Population.

—The Republic of Paraguay is divided into 20 electoral districts, which in turn are subdivided into 93 departments. The districts are numbered I to XX. Their populations, capitals and populations of the latter are as follows:

DISTRICTS	Population	Capital	Population
I.....	34,580	Villa Concepción..	12,600
II.....	37,429	San Pedro.....	8,926
III.....	36,195	Altos.....	8,715
IV.....	30,262	Barrero Grande..	9,143
V.....	31,182	San José.....	9,120

* In dispute with Bolivia.

Army and Navy.—The Paraguayan army is drilled, trained and armed on the German model. It comprises about 100 officers and 2,500 men, distributed in five centres. The

Mauser is the infantry arm. A two-year compulsory service law has been in operation since 1914, but it appears to be enforced only in the case of refractory elements of the population. The navy is composed of a number of converted merchant vessels armed with modern guns. The largest is about 600 tons gross register.

Banking and Finance.—The Banco de la República (authorized capital \$20,000,000 gold, \$6,000,000 already subscribed) and the Banco Mercantil del Paraguay (authorized capital, in terms of the depreciated currency described under *Monetary System*, 25,000,000 paper pesos and 20,000,000 paid in, both have headquarters in Asunción. The Banco de España y América, with main offices in Buenos Aires, has a branch in Asunción (capital \$2,200,000 gold). Some of the smaller cities have agencies of the foregoing. The normal banking rate is 12 per cent annually. The Banco Agrícola (capital originally 15,000,000 pesos legal money and recently increased to 30,000,000 currency pesos) has official standing as an institution authorized to assist farmers and manufacturers with loans at a reduced rate of interest and also to supply advice and instruction in regard to methods of cultivation.

The internal debt, as stated in the *Financial Congress*, was \$559,675 gold and 11,564,572 currency pesos; to which amount \$394,119 gold and 33,913,373 currency pesos are to be added as the aggregate of individual claims for damages sustained "during past epochs of revolution." The balance of the treasury's debt to the Banco de la República, of \$615,995.43, was adjusted by grant of a privilege connected with a certain tax imposed on exports. The recent issue of 60,000,000 pesos, paper, has nearly doubled the amount outstanding, which is now 125,000,000 pesos equivalent to 8,333,000 gold pesos, approximately. In 1919 the amount of the foreign debt, arising from the loans of 1871 and 1872 made in London, was \$3,679,705. The government's chief sources of income are customs duties on imports and exports, land and postal taxes, internal consumption revenues, etc.

Monetary System.—The nominal unit of Paraguay's monetary system is the gold peso of Argentina weighing 1.6129 grammes of gold .900 fine, or say 1.4516 grammes of fine gold (par value \$0.96475, currency of the United States), but in actual circulation we find only inconvertible notes of almost incredibly slight purchasing power. Large amounts may be "reduced to gold" theoretically at the rate of 1.500 per cent, according to an authoritative statement in the *Par American Financial Conference Proceedings*, 1915. The fact that practically no gold or silver coins circulate in Paraguay, the currency being limited to the depreciated paper, is mentioned in *Latin American Monetary Systems and Exchange Conditions*, by Joseph T. Cosby (New York 1915). Mr. Cosby adds: "No provision is made for the redemption of the outstanding notes, with the exception of a small volume of notes known as Moneda Nacional"—this national money being guaranteed by a gold reserve of one-tenth of the issue, and having a stable value on that basis. When fractions of the paper peso in the form of nickel coin were placed in circulation, the paper currency depreciated so rapidly that the intrinsic value of the nickel coins soon ex-

ceeded their monetary value. Therefore, those coins, tending to disappear from circulation, occasionally are sold as curiosities. Only in foreign remittances do we note the employment of exchange payable in gold and commanding a high premium.

Waterways, Railroads, Post Offices, etc.—River steamboats maintain communication between the capital and the city of Buenos Aires, and a railway, with train ferry across the Alto Paraná from Posadas to Villa Encarnación, also connects the same cities. The upper reaches of the Paraguay River above Asunción and, to a limited extent, the lower Alto Paraná are navigable—in many places precariously; even below Asunción, indeed, the channels shift suddenly and are hard to find. Travel and transportation between Paraguay and the great world outside are thus difficult, inadequate and controlled by a single foreign state; naturally, therefore, the landlocked country is seeking now by pacific arrangement, as it sought in the last century by force of arms (see *History*), its exits and its entrances—among which there is to be mentioned the projected line of railway from Asunción to Paraná, near the magnificent falls of Yguazú, and thence by a Brazilian line to the Atlantic Ocean. The baffled yet admirably hopeful country has 400 post offices and 2,000 miles of telegraph lines, with stations at all the chief towns from Asunción southward. There are wireless telegraph stations at Asunción, Encarnación and Concepción.

Government.—The constitution of 1870, now in force, vests the powers of the government in three co-ordinate branches, the legislative, executive and judicial. The National Congress, consisting of Senate and Chamber of Deputies, meets each year at Asunción. Senators, elected by the people, by universal suffrage, one senator for each 12,000 inhabitants, serve for six years. Deputies, similarly chosen, but in the proportion of one for each 6,000, serve four years. "The executive power," says the constitution, "shall be vested in a citizen, to be called President of the Republic of Paraguay. In case of sickness, absence from the capital, death, resignation or dismissal of the President, the executive power shall be exercised by the Vice-President." Both President and Vice-President are chosen by an electoral college, serve for four years and "cannot be re-elected except after the lapse of two presidential terms." The electoral law of 30 Nov. 1916 provides for 20 senators and 40 deputies. The senators and deputies receive each \$3,000 per month. Numerous provisions of the constitution are designed to guard against the revival of dictatorships, or undue extension of the powers of the executive (see section *History*). In regard to the cabinet, article 104 provides: "Five ministers or secretaries, respectively called of the Interior; Foreign Relations; the Treasury; Justice, Worship and Public Instruction; and War and the Navy, shall attend to the business of the nation, and legalize with their signatures the acts of the President. Those acts without their signatures shall have no efficacy." To the foregoing, the Ministerio de Fomento (department of promotion) has been added, making the number of cabinet members at present (1919) six instead of five. These ministers are responsible to Congress. The

judicial power is vested in a Supreme Court, consisting of three justices and having "the right to inspect and supervise the action of all inferior courts"—that is, in practice, the courts of appeal, and criminal, police, first instance, and justices' courts.

An interesting side-light is thrown upon the constitutional provisions designed to curtail the chief executive's authority when we recall the circumstances that prior to the war with the Triple Alliance Paraguay had no debt, either domestic or foreign. Her first foreign loans were negotiated in 1871-72 at London; and on 31 Dec. 1901 the debt thus contracted amounted to \$4,787,077.86. On the same day, the Brazilian and Argentine indemnities, results of the war, amounted to \$9,876,466 and \$9,563,990 respectively.

History.—Sebastian Cabot, in 1527, explored the Paraná, and sailed up the Paraguay to the mouth of the Bermejo in the following year. Hoping that a passage to the land of gold and silver mines, Upper Peru or Bolivia, would be found in some part of this great river-system (a hope which still leads explorers along the courses of the Pilcomayo and Bermejo), 300 Spanish adventurers, in 1536, proceeded up the Paraguay to the site of the present city of Asunción, where they built a fort. This outpost became a centre of military enterprise, and, after 1609, of missionary work among the natives. The Spanish province of Paraguay embraced the whole region south of the Portuguese possessions in Brazil and east of the Andes until 1617; but when Buenos Aires was made a provincial capital the jurisdiction of the governors, afterward viceroys, at that city extended over the settlements on the Paraguay and its tributaries, as well as those on the Paraná and La Plata. The Argentine general, Belgrano, incited the Paraguayans to revolt against Spain in 1810. On 14 May 1811 Pedro Juan Caballero with a few companions took possession of the Spanish barracks, and the next day compelled Governor Velasco to divide his authority with two leaders of the revolution. An assembly which began its sessions on 11 June 1811 renounced allegiance to Spain, and this declaration was ratified by the Congress which assembled for the first time on 1 Oct. 1813, and on the 12th vested the executive branch of the government in two consuls, Dr. José Gaspar Rodríguez de Francia and Fulgencio Yegros. Dr. Francia became dictator (1813-40). After his death the Paraguayans experimented with a government of four military officers, which was superseded by a triumvirate on 23 Jan. 1841; the triumvirate in turn was replaced by two consuls on 12 March, and next, from 1844 to 1870, the whole power of the state was grasped by Carlos Antonio López and his son and successor Francisco Solano López. The younger López made deliberate preparations for a war of conquest. When the time was ripe for action, he issued, through Congress, a declaration of war against Argentina, 18 March 1865. Argentina, Brazil and Uruguay formed an alliance to oppose him. Paraguay was defeated and almost depopulated in a struggle which ended with the death of López, 1 March 1870. A comparison of the official census of 1857 with that of 1873 shows, allowance being made for increase at the normal rate between 1857 and 1865, that

Paraguay lost more than 1,200,000 inhabitants during the war—her entire population, except 28,746 men and 202,333 women and children. It is proper to assume exaggeration in the earlier census, while the later one was undoubtedly defective; but, even so, the disaster must be regarded as the severest that any small nation in recent times has sustained, rising from such a trial still resourceful and independent. To Brazil, Paraguay ceded the territory on the north and northeast; to Argentina, by the treaty of 3 Feb. 1876, the district south of the Pilcomayo. But a distinguished arbitrator, the President of the United States, 12 Nov. 1878, awarded to Paraguay a district north of the Pilcomayo, which Argentina claimed. During the last decade the resort to arms for the decision of political disputes has not been discontinued; and if we review the entire period since 1870 (see section *Government*) we realize the force of the statement that "only three presidents (under the Constitution then adopted) have been allowed by revolutionists to complete the term of office." Recent disturbances of the public order were those of 2 to 4 July 1908, which led to President Ferreira's resignation; of 1910 and 1911, when Manuel Gondra and Albino Jara were compelled to resign; of 22 March 1912, in view of which President Pena and his Cabinet took refuge on foreign warships; of 27 April to 13 May the same year, when the revolutionary efforts came short of success, and within a week Eduardo Schaerer was elected to the presidency for the four-year term beginning 15 Aug. 1912; of January 1915 (the Escobar revolt) when another revolutionary failure was recorded and martial law was declared. On 19 July 1915 a treaty was signed with Bolivia, the aim of both countries being to secure, if possible, a just and amicable settlement of difficult questions relating to the boundary dispute and conflicting titles to the Chaco.

MARRION WILCOX.

PARAGUAY RIVER, South America, the largest affluent of the Paraná River (q.v.), with its source in the plateau of the Matto Grosso,

Brazil, about lat. $14^{\circ} 24' S.$, near the town of Diamantino. It flows southward through Brazil, forming for some distance the boundary with Bolivia, and enters Paraguay at Confluencia, where the three states meet, then continues the remainder of its course southward through the republic to which it gives its name. At Tres Bocas on the Argentina frontier the Paraguay flows into the Paraná. Its total length is about 1,300 miles.

PARAGUAY TEA. See **MATÉ**.

PARALLAX, a term used in astronomy to designate the displacement in the apparent direction of a heavenly body caused by a change in the position of the observer. Let A and B be two points from which the body P is conceived to be viewed. An observer at A will see the body as if on the celestial sphere in the direction A P. An observer at B would see it

in the direction B P. It is evident that the difference of these directions is equal to the angle at P between the lines A P and B P. It follows that if the length of the line A B, and its direction, are accurately known, and if the observers can determine simultaneously the exact direction in which the body, P, lies, the angle P of the triangle will also be known. Then the distance A P or B P of the body from either of the observers can be computed by trigonometric methods. The following are the principal applications of Parallax in astronomy: The distance and direction of a planet or other heavenly body, has to be calculated by the astronomer, in the first place, as if they were measured from the centre of the earth. But the observer is necessarily on the earth's surface. Parallax is then the difference between the direction from the centre and that from any station which the observer may chance to occupy. The right ascension, declination and distance of the body will all be different according as it is measured from the earth's centre, or from the eye of the observer. We thus have Parallax in R. A. and in Dec., which is mostly used in the case of the moon and planets.

The only method of determining by direct measurement the distances of the bodies of the solar system is through observations of their parallax. It is evident that the nearer the body, the greater will be its parallax. Hence, in order to measure a distance in this way, it is necessary to choose the times when the body is nearest to the earth. The moon, being much the nearest of all the heavenly bodies, has the largest parallax of all. Its average value is a little less than 1° (about $57' 2''$); but, when nearest the earth, it exceeds 1° . Being so large, even the ancient astronomers were able to measure it and thus determine approximately the distance of our satellite. Measures of the moon's parallax in modern times have been made by comparing its altitude, or declination, as it passes the meridian, at different observatories in the two hemispheres. The Greenwich Observatory and that of the Cape of Good Hope have used their observations for this purpose.

Determinations of parallax can be made

without the observer changing his position on the earth's surface, because as the earth rotates on its axis the observer is carried around with it. He thus sees the moon or a planet in different directions, according to the different points of its apparent diurnal course. The general effect of parallax, as we can readily see, is to make the moon or a planet appear somewhat nearer the horizon than it really is. If a body is rising in the east, the change thus produced in its apparent direction from the observer increases its right ascension. In the west the same effect diminishes the right ascension. Thus, by making observations of the moon or a planet in the east and in the west alternately, its parallax, and therefore its distance, can be determined. This change is called the *diurnal parallax*. The diurnal parallax of Mars has thus been determined by various observers. If the position of the sun on the celestial sphere could be determined with the utmost precision, its distance could be measured by its diurnal parallax. But as this luminary cannot be seen at the same time with the stars in its immediate neighborhood, it is not possible to make any very exact determination of the sun's parallax by direct observation. What is done instead of this is to measure the parallax of various planets, using the principles explained in theoretical astronomy. (See ASTRONOMY, THEORETICAL). In recent times those asteroids which came nearest to the earth have been mostly used for this purpose; in particular, the discovery in 1898 of an asteroid moving in so remarkable an orbit that it periodically approaches nearer the earth than any other heavenly body except the moon will lead to a value of the solar parallax far more accurate than can be determined by any other method. See ASTEROID.

Annual Parallax is that due to the motion of the earth in its orbit. It is applied only to the fixed stars. By the parallax of a fixed star is meant the difference in its direction, as seen from the sun, and from either extremity of the earth's orbit. It is, therefore, equal to the angle subtended by the radius of the earth's orbit when seen from the star.

The determination of annual parallax is far more difficult than that of diurnal parallax since, on account of the great distances of the stars, their yearly parallactic displacements are, in the great majority of cases, wholly beyond our powers of detection by any instrumental means which we possess. It was not until 1838 that the processes of practical astronomy had become sufficiently refined to permit the direct measurement of the parallax of any star. In this year Bessel determined the distance of the small, 5.6 magnitude, star 61 Cygni; the annual parallax of this is but 0.41 which corresponds to a distance of eight light years. The nearest of all the stars so far discovered is a brilliant double star of the southern heavens known as Alpha Centauri; the annual parallax of this is 0.76, which corresponds to a distance of 4.3 light years. All earlier determinations of parallax were made by direct measurement at the telescope; very recently, however, an extraordinary increase in accuracy has been attained by the employment of photographic methods and this work is being so vigorously prosecuted at many of the larger observatories that our knowledge of the absolute distance of

the nearer stars is each year becoming rapidly extended. See ASTROPHOTOGRAPHY.

SIMON NEWCOMB.

PARALLELISM, a parallel or comparison used in any sense of the word parallel. By Spinoza the term is used to suggest that every material object has corresponding to it an ideal counterpart. In psychology the word is used of the connection between matter and mind, notably between brain processes and mental processes.

In literature parallelism is a double statement of the same notion, either by simple variation of the idea or by negation in the second member of the opposite of the statement in the first.

PARALLELISM, in biology, is another name for what is more commonly termed *convergence*, expressing a phase of organic evolution. It appears in accordance with a law that similar methods and necessities of physical growth in reaction to the environment will produce likeness of bodily form and adaptations in animals of different stocks, as, for example, marine mammals and fishes, birds and insects, or between animals of the same order; and in the last-named case (most frequently observed among insects) it is often disputable whether many of the instances are to be attributed to parallelism or to mimicry (q.v.). The similarity noted above is most manifest in the field of locomotion where virtually the same mechanical problems must be met by very different kinds of animals, as, for example, in overcoming the resistance and tenuity of the water by fishes, and of the air by flying birds and bats. Here the objects to be gained by process of adaptation of a vertebrate type of structure to the same purposes, and in similar media, are buoyancy, progression and agility, and the continued effort to attain them have produced in creatures very unlike one another otherwise similarity in outline of body, and in instruments of propulsion (wings or fins and tail), which in some cases is very striking. Such parallelism in adaptation results from the fact that, as Osborn states it ('Origin of Life,' 1917), "the production of externally similar forms in adaptation to similar external natural forces," is one of the laws or modes of organic evolution.

PARALLELOGRAM, in mathematics, a quadrilateral rectilinear figure which has its opposite sides parallel. See GEOMETRY.

PARALLELOGRAM OF FORCES. See MECHANICS.

PARALLELS. See GEOMETRY.

PARALLELS OF LATITUDE. See LATITUDE.

PARALYSIS, a loss of muscular power, whereby contractility is either abolished or greatly diminished. Loss of sensation, general or special, was formerly spoken of as sensory paralysis, to distinguish it from a loss of muscular motion, or motor paralysis. At the present time the term paralysis is usually limited to denoting motor paralysis, and defects in sensation are considered under the head of disorders of sensation.

Palsy is a term rarely used by physicians, but popularly it is a synonym for paralysis. Paresis is a partial or incomplete motor paralysis, but

the term is seldom used by physicians except as referring to a disease of the insane, known also as general paresis (q.v.) or paretic dementia, in which gradually increasing motor paralysis and disorders of sensation are prominent.

Paralysis may affect either the voluntary or the involuntary muscles. It may be limited to one muscle or group of muscles, constituting a local paralysis, or it may involve those of various parts of the body, or nearly all the voluntary muscles, and is sometimes associated with sensory disturbances, such as impairment of common sensation, or alterations in the temperature of the skin. Paralysis is not a disease, but the result of some mechanical obstruction, of some functional disorder or structural damage in the nervous system (to nerves, nerve-centres, nerve-cells or other constituents), or of degenerative atrophy of the affected muscles. As a consequence of the conditions named, either the proper transmission of motor nervous impulses is prevented, or the debilitated muscles are not capable of contracting, though the impulses may be normally transmitted.

If paralysis is long continued, degenerative changes occur in muscular and nerve fibres, resulting in wasting of the parts supplied by the nerves affected, and consequent permanent inability of these parts to perform their functions. Some of the causes of paralysis are pressure of a tumor, or of a broken bone, as of the skull or a vertebra; an exudation of blood (due to diseased arteries, external injuries, etc.); an embolus disintegration of nervous tissue by softening or thickening; an accumulation of serum, or other results of inflammation. It may occur without any discoverable lesion, as in hysteric or emotional paralysis, in alcoholic paralysis, in decubitus paralysis, due to pressure on a nerve from lying for a long time in one position, and in temporary paralysis due to drugs or hypnotic or hysteric conditions.

The forms of paralysis are numerous. The names assigned to them usually refer to the situation in the neuromuscular apparatus of the damage, lesion or defective activity producing the paralyzes; to the condition of the muscles affected; or to the extrinsic causes of certain paralyzes or the discoverers of those causes. The forms of paralysis include: Acute ascending (Landry's paralysis), often fatal, beginning in the muscles of the feet and ascending to the other muscles of the body—cause not known; birth, due to injuries at birth; bulbar, due to changes in motor centres of the medulla oblongata; Bell's, a facial paralysis (see BELL'S PALSY); central, due to a lesion of the brain or spinal cord; cerebral, due to an intracranial lesion; crossed, paralysis of one side of the face and the other side of the body; crural, chiefly affecting the thigh or thighs; diphtheritic (also post-diphtheritic), a partial paralysis chiefly of the muscles of the soft palate and throat, often following diphtheria; Cruveilhier's or progressive muscular atrophy; divers', or caisson disease (q.v.); galloping, a rapidly progressive form of general paresis; Indian-bow, paralysis of the thyro-arytenoid muscles; infantile, or poliomyelitis anterior; ischemic, a local paralysis due to a stoppage of the circulation by an embolus, a thrombus, etc.; lead, due to lead-poisoning; multiple, a complication of local paralyzes;

neural, originating in the nerves; and spastic, a variety marked by rigidity of muscles and heightened tendon-reflexes.

Paralysis is further distinguished with reference to its course, as syphilitic, traumatic, toxic, etc., according to the nerve, muscles or part specially affected; as, obturator, ulnar, brachial, dental, etc. A paralysis may be reflex, due to peripheral irritation. Monoplegia is a paralysis of a single part of the body; diplegia, a bilateral paralysis, affects like parts on either side of the body.

The two most extensive forms of paralysis are hemiplegia (q.v.), paralysis of one side of the body, and paraplegia, paralysis of the legs and lower part of the body. In both forms there may be a loss of sensation as well as of motion. Although hemiplegia is usually the result of a cerebral hemorrhage or embolism, it may result from lesions of the spinal cord, or as a hysteric complication. Paraplegia is due to some lesion in the spinal cord.

The treatment of paralysis must depend very largely upon the cause, and should be in the hands of a physician, although the patient can assist materially by faithful attention to hygienic measures, and by exerting the will-power upon more delinquent muscles. Passive movements of the muscles by various forms of massage and the use of electricity are of value, but must be carefully employed, or they may do harm. Acute ascending paralysis as described by Landry in 1859 is characterized by a weakness beginning in the legs, proceeding to complete paralysis, extending usually within a few days to the body muscles and to the arms and terminating fatally in the majority of instances by involvement of the respiratory muscles. It is regarded as a symptom—complex rather than a disease. It is always dangerous, death occurring even after several weeks. Treatment is not very promising unless some definite etiological factor can be made out. Thus salvarsan appears to have caused a recovery in one case in which there had been a previous syphilitic infection.

Paralysis agitans is essentially a disease of advancing years, rarely occurring before 40 and mostly after 50. Heredity plays but a small part in the etiology of the disease for which it is usually impossible to assign a direct cause. Worry, grief, fright, overwork, hardship, exposure or acute disease appear to be the exciting causes. Its characteristic feature is the tremor, which is usually also the first symptom of the disease. The speech is often altered in the disease, the true nature of which is still unknown. It is of slow progress and may be of many years' duration, death being usually due to an intercurrent disease. Avoidance of excitement is important, warm baths afford some relief and a combination of active and passive movements has been found very beneficial in many cases. Care must be taken not to fatigue the patient. The drugs most commonly administered are the mydriatics, belladonna, atropine, hyoscyamine, hyoscine and duboisine sulphate. Care must be used in their administration as they are poisonous in large doses.

Diphtheritic paralysis is a sequel of diphtheria involving the paralysis of certain muscles. It is treated as multiple neuritis. After the

acute stage has passed, fats, tonics, especially strychnine and cod-liver oil, a course of galvanism and massage of the affected muscles are resorted to with success in nearly all cases.

PARAMARIBO, pâr-â-mâr'ibô, Dutch Guiana, South America, the capital of the colony, on the west bank of the estuary of the Surinam River, 10 miles above its outlet on the Atlantic Ocean. It is a well-laid-out town, with substantial buildings and an excellent harbor defended by two forts. The whole trade of Dutch Guiana centres in Paramaribo. Pop. about 37,035.

PARAMATTA. See PARRAMATTA, NEW SOUTH WALES.

PARAMECIUM, or **SLIPPER ANIMALCULE**, an oval, flat infusorian very common in pond water or in vegetable infusion. Each paramecium is covered with rows of cilia which lash it through the water and drive food-particles into an aperture which serves as mouth. As the food-particles enter they take bubbles of water with them, and are moved round and round in the living substance until they are digested or got rid of. There are two (excretory) contractile vacuoles; the large nucleus has a small one (paranucleus) lying beside it; beneath the thin rind there are remarkable eversible threads. A paramecium often divides transversely into two; these two repeat the process and with continually diminishing size rapid multiplication may thus proceed for a while. It has its limits, however, and then two individual infusorians conjugate, exchange some of the material of their paranuclei, and separate. Thus they seem to renew their youth. See INFUSORIA.

PARAMETER, in *mathematics*, a term applied to a constant quantity entering the equation of a curve. The term is principally used in discussing the conic sections.

PARANÁ, pâ-râ-nâ', state of the Brazilian Confederation, bounded on the north by São Paulo, on the east by the same state and by the Atlantic, on the south by Santa Catharina and the northeastern tip of Argentina and on the west by Paraguay and Matto Grosso. The main northern and western boundary is the Paraná (and the Paranapanema); and the Iguassú forms the greater part of the southern boundary. The Ivahy and Piquiry flow northwest into the Paraná; but, like the Iguassú, they are filled with rapids and unfit for navigation. The short coastline has the excellent harbor of Paranagua; and the coast is picturesque, but hot, humid and fatal with its yellow fever. In the forest-covered interior, which is only partially explored, the climate is more equable and much cooler; the temperature averages about 17° C., with a winter mean of 14° and a summer mean of 18°; and the rains are abundant. Manioc, Indian corn, coffee and cotton grow on the coast, and the cereals and fruits of the northern and central United States in the interior. There are valuable (but unexplored) supplies of iron, mercury and gold, and there are coal deposits. There are valuable pine forests, and the state is a great source of the supply of matté. The port of Paranagua is connected by a railroad with the capital city of the state, Curitiba (pop. 50,000). The area is

85,451 square miles and the population, largely increased by German and Polish immigration, is nearly 406,000.

PARANÁ, or **BAJADA** (bâ-hâ-dâ') **DEL PARANA**, Argentina, capital of Entre Rios province, on the left bank of the Paraná, the terminus of a branch railroad from Concepción. It is connected by daily steamer with Santa Fé on the west bank of the Paraná. It is well laid out, with straight unpaved streets, telephone and street car service and other modern improvements. The city was founded in 1730; was the federal capital 1852-61; is the location of the provincial university, and has steamship connections with Buenos Aires; ships of 6,000 tons come up the Paraná as far as this. But the city is not so prosperous as it was 50 years ago. Pop. 65,000.

PARANÁ, the second largest river of South America, with a length and discharge greater than those of the Mississippi and a drainage area nearly as large. Its annual flow is three times that of the Saint Lawrence and five times that of the Nile. It is the principal tributary of the great estuary called the Rio de la Plata, which it forms by its juncture with the Uruguay. The Paraná itself is formed by the confluence of the Paranahyba, which is sometimes considered its upper course as being the axial stream, and the Rio Grande, the true upper course. The latter rises only 60 miles from the coast on the west slope of the Sierra de Mantiqueira, near Itatiaya; flows east across Minas Geraes; separates that state from São Paulo, and receives the Sapucahy and the Mosy-Guassu before its juncture with the Paranahyba (q.v.) at the meeting-point of Matto Grosso, Minas Geraes and São Paulo. The Rio Grande itself is sometimes called the Pará or Paraná, but the latter name is more properly used of the double stream, which flows southeast across the Brazilian plateau with several splendid cataracts and many great rapids, the most notable being at Salto Guaira, the beginning of the river's middle course, in which it is the boundary between Brazil and Paraguay, and then between Paraguay and Argentina. It joins the Paraguay river (q.v.) just above Corrientes, which takes its name from this juncture, and then flows a little west of south through Argentina, turning to the east at Rosario, and a few miles above Buenos Aires joining the Uruguay. In general the upper course of the Paraná is navigable save at the falls of Urupunga and Guaira and at the rapids extending 150 miles below Guaira; most of its minor tributaries join with cataracts, that of the Iguassú, which, apart from the Uruguay, is nearly the only confluent from the left, being the most majestic. Through the Argentinian plain the river is broad and easily navigable; near the embouchure there is a constantly shifting delta, the main difficulty of navigation. Ships of 10,000 tons drawing 23 feet of water easily make their way 400 miles from the ocean to Rosario. Steamers drawing 13 feet ply from Corrientes to Asunción, on the Paraguay River, at any season, and at high water to the juncture of the Iguassú. The depth of the river varies greatly with rains and melting snows, and the volume is much greater at Corrientes than below. The Paraná is 2,720 miles long from its source to

the Plata. Consult Hutchinson, 'The Paraná' (1868).

PARANAQUA, pā-rā-nā-gwā, Brazil, port of the state of Paraná (q.v.), southeast of Curitiba, the capital, and on the southern side of the Gulf of Paranagua, which is navigable for vessels of 300 to 400 tons and is separated from the Atlantic by the Ilha do Mel. Railroads built by French enterprise connect the city with Curitiba and with the harbor at Antonina; and there is regular steamboat connection with Hamburg, because of the German colonists in the state and the valuable exports of maté, hardwoods, cereals and sugar. Pop. 6,000.

PARANAHYBA, pā-rā-nā-ē'ba, or **PARANAHYBA**, pār-nā-ē'bā, Brazil, (1) a city and seaport of the state of Piauí, on the river of the same name, about 10 miles from the coast and 50 miles north of Pernambuco, with which and Natal it has rail connections. It is an unhealthy town, but of importance as the seaport for the region. Cotton and sugar are the principal exports. Pop. (estimated) 20,000. (2) A river of northeastern Brazil, rising between the Serra das Mangabeiras and the Serra Gurgueia, and forming the boundry between Maranhão and Piauí. It is more than 630 miles long, has no rapids in its course to the northeast and is navigable for 400 miles. It empties into the Atlantic through six mouths, forming a large delta, to the east of which is the city of Paranaíba (q.v.). The affluents of the river are the Gurgueia, Piauí, Poty and Longa from the right and the Balsas on the left. (3) An affluent of the Paraná (q.v.), rising on the boundary of the states of Goyaz and Minas Geraes in the Serra dos Vertientes. It forms the line between the two states mentioned, receives at the left the Velhas and the Tepico rivers and on the right the Corumba and the Meia Ponte, and joins the Rio Grande de Paraná (or Paraná), with which it forms the upper waters of the Paraná (q.v.). The Paranaíba occupies the axis of the Paraná basin, but cannot be reckoned the true headwater of the Paraná because of its short course and small volume of water as compared with the Rio Grande. Above its juncture it forms several cascades and rapids. It measures altogether more than 520 miles.

PARANOIA, one of the types of the psychoses. It is characterized by a marked hereditary predisposition, a slow development of persecutory ideas, almost from childhood, with increasing inability to get on in the world, and it usually terminates in a mild type of mental disintegration. Its subjects are the people with pronounced mental twists, sometimes antisocial, more often able to get along in society if they are able to be let alone. The disease is one of great importance, and yet the conduct of those affected is often so closely allied to the average conduct of the environment that it becomes extremely difficult to come to the decision of mental irresponsibility in many of these cases. Although a rare disease, it is particularly important to recognize it, since paranoiacs are often very dangerous lunatics. The murderer of Garfield was an example. A typical case usually starts wrong in the world, with

a mental instability inherited from intensely neuropathic parents. Some type of mental disease or extremism or pronounced crankiness or violent temper is present in the crankiness of most of these cases. Throughout the developing period these children are usually different from other children; their intellects may be as bright as others; very often they are precocious, but irregularly so, being generally below par; they are apt to be less gay, less expansive; are characteristically introspective, frequently very egotistic and inclined to live within themselves. They think that their parents are less fond of them and show favors to their brothers and sisters. They thus come to be very subjective and live in a realm of fancies and ideas, are notoriously poor observers of fact as entities and poor scholars in the exact sciences. If they are recognized as different in these early stages much may be done for them by appropriate psychoanalysis. After reaching years of independence these patients find it difficult to get along with people. They are suspicious and quarrelsome and soon come to believe that they are the objects of special plots and persecutions. The early childhood ideas may be a nucleus for this delusional type of thinking. This false interpretation of conditions about them becomes more and more fixed in their minds until it is systematized and everything is woven into the fabric of this belief. Many persist in this state for years. They may be engaged in business, but are more apt to follow some solitary pursuit. Here their eccentricities, if coupled with a small modicum of talent, are put up with and they go along as actors, painters, musicians, writers, inventors, etc., earning perhaps a bare living or being half supported by friends, while they are laying the foundations of a "career." Often the ideas of persecution lead to the development of intense hatred, it may be of an individual as a personal aggressor or as a hindrance to the cause of truth, of liberty, of freedom, etc. It thus comes about that many paranoiacs are attracted by the doctrines of anarchy and it is notorious that regicides are prominently represented in this diseased type. Some of these patients at periods of excitement suffer from hallucinations; they see faces, hear voices plotting against them, etc. Sometimes these voices seem to accuse them of immoral acts. From ideas of persecution they often graduate into ideas of grandeur (see GENERAL PAREISIS). Sometimes the voices appear to tell one of these that he is elected by God to be the savior of his people and in response to either set of hallucinations he may kill. Mystico-erotic ideas are very frequent in women of this nature and many are found studying Oriental philosophies and mystic symbolisms from fakirs who hold their hands and teach them breathings, intestinal lavage and various forms of massage—all of which contribute to their erotic tendencies. One feature is very characteristic in this disease—its oneness. On many of the topics of general conversation the paranoiac is rational and often a charming talker; but touch the core of his delusional state and he is transformed. Some part of his thinking necessary to bring about mature judgments along certain lines is defective. This defect has never yet been seen by the microscope, but

there seems to be little doubt that some organic brain defect may develop. Most of these cases are hopelessly incurable. A few remit, are apparently self-controlled for a time and then develop. The majority go on to a mild form of dementia, but the breakdown is very slight, although the delusions usually persist and dominate the patient's whole thought and actions. The anti-social patients are best confined in sanatoriums. They are nuisances to all and are better under the strict régime of an institution. Much can be done by early individual training to render these defectives self-supporting. Consult Jelliffe and White, 'Diseases of the Nervous System' (3d ed., 1919).

SMITH ELY JELLIFFE, M.D.,

Editor, 'Journal of Nervous and Mental Disease.'

PARANTHRACENE. See ANTHRACENE.

PARAPEGM, in ancient times the name given a tablet fixed to a pillar or wall and on which laws and proclamations were engraved.

PARAPET, (1) in fortification, a work, usually of earth, intended to protect the troops within the ramparts, as well as the pieces of artillery used in the defense. It has three sloping surfaces, an outer, upper and inner; but the upper surface slopes very gently downward and outward. It is intended for the defenders to rest their rifles or muskets on when firing. The defenses round the roofs of castles are also called parapets. (2) In architecture the term parapet is applied to the structures placed at the edges of platforms, balconies and roofs of houses to prevent people from falling over.

PARAPLEGIA. See PARALYSIS.

PARASANG (Gr. *παρσαγγης* from Persian *parsang* or *farsang*), the denomination of a lineal measure among the Persians of antiquity, and still used by them. In Xenophon's account of the Retreat of the Ten Thousand he gives the length of each day's march in parasangs, and modern travelers agree with the estimate he makes of its length, namely about 30 Greek stadia. Herodotus makes about the same estimate, which in English miles would be a little less than three and one-half. Strabo, the geographer, reckons it as an arbitrary measure of 30, 40 or even 60 stadia, and the nature of the ground traveled over may sometimes have had some influence in determining the question. The derivation of the word, which means "stone-at-the-end," points to the fact that the Persians, like the Romans, marked out their great highways by means of stones, inscribed with the distance in one case from the Persian capital, in the other from the "golden milestone" (*milliarium aureum*) which Augustus set up in the Forum near the temple of Saturn.

PARASELENE, in astronomy, a mock moon, not unlike the Parhelion, or mock sun. The Paraselelene is common in the polar regions. See HALO.

PARASITES. A parasite is an organism which draws its sustenance from some other living thing on the surface of which or within the body of which it lives. The organism upon which it depends is known as the host. Either parasite or host may be equally either plant or animal. The plant parasites, which include such forms as molds, rusts and especially bacteria, are found in and upon all sorts of plants and

animals and are the cause of a variety of diseases that assume in different places and at different times great economic importance for man and also affect him directly and seriously in the form of a multitude of human diseases. The phytoparasites just noted are not specifically discussed under this heading, but are treated in individual articles dealing with the groups mentioned. The zoo-parasites that form the subject of this special discussion are less widely known. They stand in the same relations both to plant and animal hosts that have been enumerated above for the phytoparasites. Recent discoveries have shown them to be of far-reaching importance in their attacks upon domestic animals and still more as the cause of human diseases. The group of animal parasites is not a systematic subdivision for the animals embraced under this heading are related biologically rather than structurally. Some branches of the animal kingdom like the Echinoderms contain no species of parasitic habit; among the vertebrates only a couple of types like the lamprey and the hag-fish manifest a parasitic habit; still other groups like the mollusks and sponges possess a few parasitic species. On the other hand the large majority of the flat worms and round worms are parasitic although in these phyla some small groups like the Turbellaria are free living. Among other groups like protozoa and arthropods the balance between free living and parasitic forms is more nearly even. This situation emphasizes the fact that parasitism is an acquired habit and this fact is abundantly demonstrated by the structure of parasitic species which shows a general likeness to that found in the free living forms yet manifests modifications directly relating to the discharge of function under conditions of parasitic existence.

The secondary character of parasitism is still further demonstrated by the wide range in degree and type of dependence exhibited by different species. In fact the various grades merge into one another so perfectly as to produce a scale of dependence that passes almost unbroken from the free living type to the most extreme parasitic organism.

These conditions are well illustrated by the barnacles (*Cirripedia*). At one end of the series stand the ordinary sessile species which are sometimes attached to the external surface of a whale as to rock or a floating object in the ocean and have no special biological relation to the organism which serves them for mechanical support. Contrasted with this are forms that seek a location within the jaws of the whalebone whale and profit by the organisms carried past them in the current of water surging through the plates of baleen while the whale is feeding. While these fall within the class of messmates or commensals and are not far removed from such as are true parasites, yet it will be noted that they do not draw sustenance from the animal itself. One member of this same group, *Sacculina*, has acquired a true parasitic habit and has become radically modified in the process. The adult is a shapeless mass firmly attached beneath the "apron" of a crab. Its relationship to the barnacles is evident when one considers the free-living young and the first stage after settling down on the abdomen of the crab which serves as host. The antennæ used by other barnacles

purely as organs of attachment develop here into an extended system of rootlets which permeate the body of the crab and serve to absorb food for the parasite.

Transition to parasitism is exemplified equally by various types of flies. There are those which live upon decaying material; others in which the mouth parts are adapted to piercing that suck the blood of various hosts, move from individual to individual and lead a vigorous independent existence. Finally the sheep tick (*Melophagus ovinus*) is really only a highly modified biting fly that has lost its wings, given up largely the power of independent movement and assumed a more intensive parasitic existence.

The relation between the parasite and the carnivore is well illustrated by leeches. In this group there are those species which manifest a purely carnivorous habit; others that parasitize upon larger animals and remain only long enough for a single meal while still others remain attached to the exterior of fish or turtles as permanent external parasites.

One sees in the temporary parasitism of the mosquito or bedbug evidently the first step toward the stationary parasitism of the fleas and lice, but such ectoparasites or epizoa are after all less highly specialized than the endoparasites or entozoa. Ectoparasites which are very common on the surface of aquatic animals are reduced among air-living species to the members of the group of arthropods whereas the soft-bodied forms like protozoa and flukes that occur on the external surface of water-living hosts have been necessitated to accept a more favorable location when the host entered upon a terrestrial existence and the external surface was hardened to the horny skin of the higher vertebrate. Natural openings furnish points of entrance by which such ectoparasites were led to invade the mouth, lungs and alimentary canal or the cloaca and bladder where are found to-day species whose close relationship to forms parasitic on the external surface of related water-living hosts is too clear to fail of recognition. Most of the entozoa belong to the systematic groups of protozoa, trematoda, cestoda and nematoda. They represent the most highly specialized members of the group and have become modified by adaptations to the parasitic mode of existence which are most numerous and striking.

The majority of internal parasites are found in the alimentary canal or some organ connected with it and owe their introduction to the contamination of food or drink. Yet there is no part of the body which is immune to parasitic attacks as certain species occur regularly in the muscular system, or the circulatory system, while even the brain and special sense organs are not without such guests.

It is interesting to note that certain species which are ordinarily free-living may under circumstances assume a parasitic habit. Thus protozoa common to slime of ponds or streams when introduced accidentally into the human alimentary canal may find possibilities for developing temporarily in the rectum. Nematodes like the vinegar eel have been found as apparently successful inhabitants of the human bladder and small leeches common in the wayside

pools when drawn into the throat by man or animals drinking may thus become accidental parasites of a temporary character.

Schaudinn has called attention to the ease with which slime-inhabiting species of microscopic animals, especially protozoans, may accidentally gain access to the alimentary system of man, and find there conditions such that they may indefinitely continue their existence. Small roundworms (*Rhabditis nigrovirens*) thrive apparently equally well in the mud or in the lung of the frog, although the method of reproduction becomes modified in the second instance.

The relations of animals to one another show also many degrees of dependency which suggest another line of origin for the parasitic habit. In the simplest case of dependency the weaker form receives shelter or even only transportation from point to point. Such are the conditions for those forms which take up their abode upon floating objects in the water, the backs of whales, or the outer surface of the shells of crabs and mollusks. Some, indeed, seek more sheltered positions, as for instance among the windings of a snail's shell or within the mouth of the whale. In the latter case the animal secures not only the best of protection but is able to pick up stray morsels of food as well. The dependent secures board as well as lodging from the host, and the relation is known as commensalism (q.v.). In some instances, however, it may be of mutual advantage, and some return may be rendered for the services performed. In the latter case the relation is known as mutualism, or symbiosis. The association here is well illustrated by that of the anemone which is regularly found attached to the shell of a hermit-crab. The anemone secures transport from point to point, greater freedom from injury, together with less dependence upon environment, than is ordinarily true of sensible organisms, while at the same time it appropriates stray morsels which fall from the jaws of the crab while feeding. On the other hand, its presence on the shell favors the concealment of the crab, and its stinging tentacles ward off possible attack. The advantage of the association is demonstrated by the solicitude with which the hermit-crab transplants the anemone when forced by growth to take a new shell for its habitation.

Diametrically opposed to this mutual advantage which has grown out of the association of lodgers and messmates is that in which the return is purely one-sided, namely, true parasitism. The parasite lives at the expense of his host without rendering any service in return, and yet with such prudence as not to endanger the life of his supporter until at least his own life-history is completed. The precision of the relation is evinced for instance by the life-history of the ichneumon-flies. The eggs are deposited in cases on the back of caterpillars; the larvæ penetrate the body of the latter and, beginning with the least important organs, devour the tissue of the host until with its complete destruction each larva is ready to metamorphose into the fly. It is but a short step from the position assumed by some lodgers in the mouth-cavity to that taken by most parasites in some region of the alimentary canal, or in one of the various organs connected with it; and yet the transition is not always to in-

ternal parasitism (endoparasitism). Existence on the external surface of the host, which distinguishes the ectoparasite, though rare on account of the greater dangers involved, presents examples of an equally intense parasitic habit. Beneath the abdomen of the crab occurs often a curious sac-shaped body (*Sacculina*) which is a near relative of the barnacles, a group of typical sessile forms. The relationship is little evident from the inspection of the adult, but is clearly demonstrated by study of the life-history. The young organism settles down on the crab, similar in form and development to a young barnacle, but develops organs of attachment which ramify through the body of the crab as do the roots of a tree through the soil, and are the sole means of obtaining nourishment. Accompanying the assumption of the parasitic habit comes the striking degeneracy of organs connected with the active life and the development merely of the reproductive function. The adult *Sacculina* consists of little more than a mass of reproductive organs producing large numbers of eggs.

Effects of Parasitism.—The effects of parasitism, which are dependent upon the degree to which the animal has acquired the parasitic habit, are equally evident and similar in parasitic forms, whatever their line of origin. The organs and function of locomotion are the first to suffer. Adult parasites possess little if any means of movement and such locomotor organs as are present in the embryo, and are related to a period of free existence or to a change of host, disappear with the attainment of the adult location. Hand in hand with the degeneration of the locomotor organs goes the reduction in the muscular and nervous systems. Organs of special sense, also, become atrophied or are entirely lost, and the parasite is degraded to the level of a mere vegetative organism by the disappearance of these characteristically animal structures.

On the other hand, while the parasitic life is an easy existence, it is equally a dangerous one for the species. Were the eggs to be deposited and the young developed at the point where the adult lives, the existence of the parasite and its host would find an evident and not distant limit. The necessary migration to the external world and search for new hosts involve large elements of chance. Thus for the preservation of the species a superabundant fecundity is required to meet these overwhelming odds. In conformity to this the reproductive system of the true parasite reaches an extraordinary stage of development, and produces an enormous number of offspring. It is noticeable that the same changes are brought about in the worm and in the crustacean. Unlike as they are at the start parasitism has degraded them to the same physiological level. Those organs which characterize the animal are lost and there remains merely a superdeveloped reproductive system. It is wise in this connection to emphasize the fact that the parasites do not constitute a group of systematic value. The forms are classified in distinct and separate branches of the animal kingdom, and a given parasite is often more closely related to free-living species than to other parasitic forms. The majority of animal parasites occur to be sure among the lower groups so that the single-celled animals (Protozoa), the worms, and the

Crustacea, furnish the larger number of parasitic animals, although instances of parasitism are not wanting in higher groups, even among the vertebrates.

Parasites do not originate in vitiated organs, as the ancient worthies of medicine would have it, nor are they the result of any peculiar temperament, as another school has held in time past. They have been introduced into the body of the host from without, and are found in a given location because the germs or embryos were brought to that point by some chance, and have maintained it during growth. The method of cure is equally evident. No amount of imagination can compass it, for it depends upon the removal of the parasite and the prevention of the introduction of further germs or embryos. The same line of reasoning applies with equal distinctness to other diseases, and if followed will materially aid in dispelling many popular illusions of the day on medical subjects.

Endoparasites.—The endoparasites of man have been centres of attention during recent years by virtue of discoveries which have demonstrated their importance in the etiology of disease. To be sure the occurrence of tape-worms, and of the larger roundworms, is recorded in the first medical writings of the Greeks, and also in the still earlier chronicles of the Hebrews and Egyptians, and in a few instances their relation to disease was accurately stated. Now more than 150 species are recorded for the human host, and the discoveries of recent years have been particularly fruitful among the lower groups of these organisms. For instance, it is now known beyond question that a small parasite in the red corpuscles is the cause of malaria (q.v.), one of the most widespread and costly of human diseases. Quite recently also smallpox, yellow fever and a number of tropical diseases of considerable importance have been attributed to the presence of other minute animal parasites. Although not yet demonstrated it may well be that the causes of many infectious diseases which have hitherto been sought in vain among the bacteria are eventually to be found among microscopic animal parasites.

In the opinion of the medical profession 200 years ago there was no disease, real or imaginary, which was not due to the presence and effect of some kind of parasite. More careful study has shown the extreme character of this view, and has given some insight into the actual effects of the parasite upon the host. In general such effect is related to the proportional size and number of the parasites, although there is an evident difference between such parasites as are active and growing and those which are encysted and passive. The draft on the host is first for food supply, which evidently depends upon the size and fertility of the parasite; in the second place upon the amount of space occupied, which will be of importance only where the number of parasites is large or the space occupied is limited; and in the third place, active parasites produce by their movements a certain irritation and inflammation of the tissues of the host. Certain species which actually devour the tissues of the host introduce an element of danger in the destruction of essential organs and through weakening the walls of blood vessels or perforating the intestinal canal,

so that the secondary consequences may be entirely out of proportion to the actual destruction caused. Excessive effects are, however, due to more intricate causes. The extreme anæmia which is consequent upon the parasitism of certain species (*Necator americanus*) is due to the constant abstraction of blood by the parasite, and the consequent great reduction in the vitality of the host. The injuries caused in the intestinal wall afford places of easy attack for pathogenic germs which may be present. Many investigators have also shown that certain species of parasitic worms produce definite poisons (toxins) which affect particularly the nervous system and the formation of blood. The continued production and giving off of such substances explain the apparently excessive results of parasitism, and the production for instance of pernicious anæmia by certain tapeworms, such as *Dibothriocephalus*.

Causes and Results.—The life-history of the parasite is intimately connected with the habits of the host, and frequently includes alternation of generations in that one generation is passed within the host and another either outside as a free-living organism or in a different host; or it may be that the larval form occurs in one host, while the adult is found in another. Thus the larval form of one tapeworm occurs in the mouse, and the adult is found in the alimentary canal of the cat. The complications which occur are too extensive to permit of detailed consideration here, but the relation of the two hosts is regularly such that the transition from one to the other is achieved by natural means. The life-history gives a clue to the means by which the parasite gains introduction to the host, and in the absence of knowledge concerning the development it is difficult if not impossible to say at what point the evil may be combated. A rational prophylaxis for malaria was not given until the life-history and the method of introduction of the parasite into the human host were laid bare. In general the causes of human parasites are to be found in the disregard of personal cleanliness on the part of the individual, in too intimate association with pet animals, from which come a number of important parasites, in the contamination of the water-supply by sewage or waste, in lack of care in the preparation of food and, of course, frequently in the element of chance.

Parasitic diseases did not affect savage man widely. While conditions of existence were very unsanitary, those who fell seriously ill were deserted and a new place of habitation sought out. Thus the sources of contamination were left behind and the epidemic stopped. When man began to live in fixed communities opportunities were given for rapid increase in the number of his parasites and for their transmission to others. Food and drink were readily polluted and epidemics became frequent and virulent. Thereby the race developed in the course of a long period a certain immunity such as is seen to-day in the resistance of the black race to the evil effects of hookworm disease. This was acquired doubtless at a fearful cost in human life as evidenced by the present effects of new diseases on non-acclimatized races or groups.

With the development of community sanita-

tion and especially with the emphasis on pure water, and with general education in personal hygiene the abundance of animal parasites and the chances of infection have been markedly reduced. The use of foot coverings and less intimate association with domestic animals are also important factors. The demand for good food with consequent greater care in raising, preparing and distributing food products also tends to reduce and ultimately to eliminate zoonotic diseases. When national customs or prejudices run counter to the favorable influences mentioned, certain animal parasites may become abundant and serious, but the increasing knowledge and intelligence of man will ultimately control and zoonotic diseases will disappear. Thereby man will surmount the greatest barrier to the control of the tropics and the utilization of its wonderful riches for the welfare of the race.

HENRY B. WARD,
Professor of Zoology, University of Illinois.

PARASITIC ANIMALS. These are generally tabulated under the headings of protozoa, worms and insects. Of the Protozoa group, *P. rhizopoda*, some amœbæ are parasitic, *P. sporozoa* are all parasitic, and there are numerous parasitic forms of the *P. infusoria*. The two first mentioned are productive of malaria in humankind. Of the Scolecida group, *S. trematoda*—liver flukes—the *S. cestoda*—tapeworms—and the four genera of *S. acanthocephala*, are all parasitic; the *S. nematoda*—roundworms—are also mostly parasitic. Of the Annelida group, some species of *A. chætopoda*—sandworms—are parasitic, while most species of *A. hirudinea*—leeches—are ectoparasites, or temporary parasites; some leeches are carnivorous. Of the Insecta group, besides many plant parasites the group of animal parasites include *pediculida*—lice; *membranacci*—bed-bugs; *aphaniptera*—fleas; *mallophaga*—bird lice; *pupipara*—sheep lice; *culicida*; mosquitoes and other *diptera*; ichneumon flies; and among the Arachnida group of spider parasites, are mites, water mites, itch and mange mites and ticks. See PARASITES; PARASITIC DISEASES.

PARASITIC CONE. See CONE.

PARASITIC DISEASES, the name applied to such human and animal diseases as are

caused by animate agents, of which there are two types—parasites and infectious agents. While the latter produce "infectious diseases," they are in a sense parasites, though they may also be saprophytes—vegetable organisms living upon dead organic matter. The true parasite, however, is not an infectious agent; it confines its habitat to certain localities of the living body and remains there. It is milder in action; its life being intimately bound up with that of the host upon whom (or which) it lives, there seems to be an absence of "intent" to destroy that host. On the other hand, the infectious agents enter every tissue of the living body and destroy it as speedily as may be. Yet parasites and infectious agents are not necessarily distinct organisms, for types of the former exist harmlessly in perhaps every human body. See PNEUMONIA.

The various diseases are dealt with in separate articles. They may be produced by vegetable or animal parasites, while a third form of infective diseases, such as influenza, whooping cough, small-pox, measles, typhus fever and mumps, have not been definitely traced to micro-organisms. The diseases arising from vegetable parasites are erysipelas, infective endocarditis (affecting the internal membrane of the heart), gonorrhœa, suppuration and blood poisoning. Specific bacilli, those which always provoke the same disease, cause typhoid fever, cholera, yellow fever, infective meningitis, diphtheria, pneumonia, Malta fever, Weil's disease (a form of jaundice), tetanus, relapsing fever, plague, glanders, leprosy, tuberculosis, madura foot, actinomycosis, asperghosis and other fungus diseases. To animal parasites (protozoa) are due the tse-tse fly disease, sleeping sickness, amœbic dysentery, syphilis (unknown origin), malaria, Kâla-azar (an Indian fever) and black-water fever. The *filaria* or nematode parasitic worms are found in various organs and in the blood. Scarlet fever and hydrophobia have also been traced to organisms. Investigations carried out in Alexandria, Egypt, during 1916, into the spread and incidence of intestinal protozoal infections of British troops and natives in the Near East revealed three new human intestinal protozoa. The following list shows the localities of the human body and the principal parasites that are found in them:

ENTOZOA.

Blood	<i>Filaria sanguinis hominis</i> .
Brain	<i>Acephalocystis multifida</i> .
Bronchial glands	<i>Filaria bronchialis</i> .
Bronchial tubes	<i>Eustrongylus bronchialis</i> .
"	<i>Strongylus bronchialis</i> .
Capsule of crystalline	<i>Distoma mobium</i> .
Crystalline	<i>Monostoma lentis</i> .
Duodenum	<i>Distoma crassum</i> .
Eye	<i>Filaria oculi</i> .
Gall bladder	<i>Distoma hepaticum</i> .
"	<i>Fasciola hepatica</i> .
Hepatic duct	<i>Distoma lanceolatum</i> .
Intestines	<i>Ankylostoma</i> .
"	<i>Anthonia canicularis</i> .
"	<i>Ascaris alata</i> .
"	" <i>lumbricoides</i> .
"	" <i>mytax</i> .
"	<i>Bothriocephalus cordatus</i> .
"	" <i>latus</i> .
"	<i>Cysticercus tenuicollis</i> .
"	<i>Distoma heterophyes</i> .
"	<i>Ditrachyrceras radus</i> .
"	<i>Eustrongylus gigas</i> .
"	<i>Œstrus hominis</i> .
"	<i>Pentastoma constrictum</i> .

Intestines	<i>Pentastoma denticulatum</i> .
"	<i>Tænia acanthotrias</i> .
"	" <i>elliptica</i> .
"	" <i>flavapuncta</i> .
"	" <i>lophosoma</i> .
"	" <i>mediocanellata</i> .
"	" <i>nana</i> .
"	" <i>solum</i> .
"	<i>Tricocephalus dispar</i> .
Kidney	<i>Sclerostoma duodenale</i> .
"	<i>Eustrongylus gigas</i> .
"	<i>Ascaris renalis</i> .
"	<i>Tetastoma renale</i> .
Liver	<i>Tænia nana</i> .
"	<i>Acephalocystis endogena</i> .
"	<i>Pentastoma constrictum</i> .
"	<i>Echinococcus hominis</i> .
Muscles	<i>Trichina spiralis</i> .
"	<i>Cysticercus cellulosæ</i> .
Omentum	<i>Echinococcus hominis</i> .
Ovary	<i>Hexathyridium pinguicola</i> .
"	<i>Polystoma pinguicola</i> .
Portal and venous system	<i>Bilharzia hæmatobia</i> .
Portal and venous system	<i>Distoma hæmatobium</i> .
Skin and areolar tissue	<i>Dracunculus medinensis</i> .
"	<i>Filaria medinensis</i> .
Spleen	<i>Echinococcus hominis</i> .
Urinary bladder	<i>Dactylius aculeatus</i> .
"	<i>Diplosoma crenatus</i> .
"	<i>Spiroptera hominis</i> .
Venous system	<i>Hexathyridium venarum</i> .
"	<i>Polystoma venarum</i> .

ECTOZOA.

This class includes the varieties of lice, the chigoe and itch-insect, which infest the skin, cellular tissue and the hair.

The chief vegetable parasites, Entophyta, those living within the body, and Epiphyta, those living on the exterior, occur as follows: In the stomach, *Torula cerevisiæ* (also in the bladder); *Sarcina ventriculi*. The *Oidium albicans* or thrush-fungus occurs on cutaneous and mucous surfaces; in the mouth, where also *Leptothrix buccalis* is found. The bones of hands and feet and deep tissue are affected by *Chionyphe carteri*. On the scalp, *Microsporon audouini*; *Trichophyton sporuloides*; *Achorion lebertii*. The skin, *Puccinia favi*; *Achorion schoenleinii*; *Microsporon furfur*; follicles of hair, *Microsporon mentagrophytes*. See BACTERIOLOGY; DISEASE, GERM THEORY OF; PARASITES; PATHOLOGY.

PARASITIC FISHES, about a dozen very small eel-like fishes, of the sand-eel family *Ophidiidæ*, and the genera *Fierasfer* and *Encheliophis*, are parasitic or commensal in other marine animals, and have some curious modifications. They frequent the hollows in the bodies of jellyfishes, the breathing chambers of starfishes and sea-cucumbers, and sometimes insinuate themselves between the layers of the mantle of pearly mussels and other bivalves. Cases are known where they have become coated over with pearl and so imbedded in the interior of the shell. These parasitic fishes have totally lost their pelvic and caudal fins; and the vent has been moved forward from the ordinary anal position to near the throat. One species (*F. affinis*) is especially common on the pearl-oyster banks of western Mexico.

PARASITIC PLANTS, plants which live upon and at the expense of other plants to which they become attached. The group is not well defined, since many of the lower forms have saprophytic habits also, or may develop them under favorable conditions and since some higher plants exhibit more or less parasitic tendencies. All members of the group are alike

in their method of feeding: sucking organs (haustoria) are developed within the host-plant's tissues, their office being to absorb the liquids which the host-plant obtains from the soil and the food elaborated by the green parts of the host. It is assumed by botanists that this habit has resulted in sexual degeneracy, so that in some cases sexuality appears to have been lost entirely. As a consequence of this the vegetative functions are in many cases remarkably developed. In other cases the life-history is remarkably complex, especially among the lower fungi, for instance, apple-rust. (See APPLE, paragraph *Diseases*). The flowering parasitic plants may or may not contain chlorophyll, in the former case being able to utilize the carbon dioxide of the air in the manufacture of a part at least of their food; in the latter case being dependent nearly if not entirely upon the host. Familiar instances of the former are bastard toad-flax and mistletoe; of the latter, broom-rape and dodder. This last (see DODDER) is remarkable also because its seeds germinate in the ground, send up slender leafless, thread-like stems, and after becoming attached to a host die at their lower extremities. Single individual plants of some species of dodder have been known to feed upon more than half a dozen different species of host-plants at the same time. From an economic standpoint, the parasitic fungi are of most importance. Among these are the so-called plant diseases; for instance, the smuts and rusts of cereals, the blight of strawberries and potatoes, the mildew of gooseberries and grapes, etc. There are also several diseases attributed to bacteria; for instance, pear blight and melon wilt. Still other members of this group are parasitic upon insects. The common house fly is frequently found stuck fast to walls and windows and surrounded by a yellowish ring of spores of a plant parasite. Young fish in hatcheries are often destroyed in immense numbers by a slime mold. Horses occasionally suffer from a lung parasite of vegetable origin. And even man is not exempt; he is sometimes attacked by ringworm and barber's itch. The attacks of these parasites are due largely, if not wholly, to unsanitary conditions, carelessness, neglect, or some other similar cause and they may be prevented by proper attention.

PARASOL, an umbrella or covering for the head, which was used among the ancients, not for the purpose so much of preservation from the rays of the sun as in religious ceremonies and processions. In certain festivals the young females who celebrated them bore, among other sacred instruments, the parasol: it was, in fact, one of the most ancient marks of dignity that we find indicated either by relics of art or by authors. In process of time, when the Romans began to lay aside the simple habits of their forefathers, the parasol, by a natural transition, began to be used for the purpose to which it is still applied. The matrons particularly used to be followed by slaves, whose office was to protect the delicacy of their charms by intercepting the solar heat by the agreeable shade of the parasols. They were constructed of wands or twigs, disposed in such a manner as to admit of their being put up or down, in much the same way as those used at the present day. See UMBRELLA.

PARASUCHIA, an order of extinct crocodiles. See HERPETOLOGY.

PARAY-LE-MONIAL, pā-rā-le-mō-nē-āl, France, town in the department of Saône-et-Loire, on the Bourbonnais, about 170 miles in direct line southeast of Paris. It is one of the oldest towns in France, and is famous for having been the home for many years of Margaret Mary Alacoque, a Visitation nun, who gave the world an account of remarkable revelations made to her regarding the devotion to the Sacred Heart of Jesus. To this nun may be given the credit, in a great degree, of the present magnitude of the League of the Sacred Heart (q.v.). She died at Paray-Le-Monial, 17 Oct. 1690. Pop. 3,000. Consult Tickell, 'Life of Blessed Margaret Mary'; Bougand, 'Histoire de la bienheureuse Marguerite Marie' (1894).

PARBUCKLE, a method of raising or lowering any cylindrical body, such as a barrel, by an inclined plane. It consists in throwing a rope round a post fixed on the level from which the object is to be lowered, or to which it is to be raised, making the ends of the rope of the same length and passing them under and round the object to be raised or lowered. In raising or lowering the object one or more men, standing on the higher level, take hold of each end of the rope, and shorten or lengthen the amount of rope paid out according as they wish to raise or lower. By this method the barrel, or whatever else it may be, is made to serve as a pulley for itself. The resistance at the two ends of the rope is just one-half of the weight of the object as felt on the inclined plane, or one-fourth of that weight at each end separately.

PARCÆ, pâr'sē. See FATES.

PARCEL, was formerly used as an adverb or semi-adverb, having the meaning of "partly" or "in some measure"; as in the expressions "parcel-blind," "parcel-deaf," "parcel-gilt" or "parcel-learned." In the law of real estate and conveying of property, the word is used for a portion of land named in the transaction of buying or selling, and so also of a description of property set forth in a conveyance, together with its boundaries, with a view to its easy identification. In nautical usage, a parcel is a wrapping of tarred canvas on a rope, to prevent chafing. It is cut in long, narrow strips, well tarred, and made up into rolls before it is laid on the rope. The rope is usually warmed, then parceled and then served.

PARCEL POST. The generic name for a service performed by governmental agencies and comprising the collection, forwarding and delivery of packages through the mails. It corresponds in a general way with the service performed by the express companies, which until the summer of 1912 were in exclusive possession of the field in the United States. At the time mentioned nearly all European and one or two South American nations, as well as Japan in Asia, were provided with systems for the transportation of merchandise in retail quantities, but within generous weight and bulk limits, at considerably less than one-third the cost of expressage in this country. The United States post office would receive no parcel of merchandise over four pounds in weight and

charged a prohibitive uncial rate. In Belgium the maximum weight transportable in the mails was 132 pounds; in Russia it was 120 pounds; in Germany, Switzerland, Hungary, Rumania, Luxembourg, Sweden and Norway the permissible mailable weight was 110 pounds, while in Austria there was no legally prescribed limit. But the parcel post charges being four or five times the prevailing freight rates, the use of the mails for very heavy shipments was practically precluded. Only 5 per cent of the number of packages forwarded by express in this country weigh over 100 pounds and universal experience attests this to be the usable limit of the service. In Great Britain, where the maximum mailable weight was 11 pounds, a package express service had been instituted by the railways themselves. Fish, game, and farm and dairy products, for instance, could be shipped 50 miles at the rate of about 12 cents (sixpence) for parcels up to 24 pounds and one-half cent a pound for greater weights without limit. For longer distances the rate increased, but the highest charges were 18 and 30 cents, respectively, for 10 and 24 pounds carried a distance of 200 or more miles, with a 1/4 cent pound rate for greater weights. Railway transportation rates in England are graduated down to two pounds for all classes of freight and a collect and delivery service is attached in all cases. The minimum parcel post rate in Continental Europe is about six cents per package. Comparisons are difficult because of the variations in the tariffs and practices, the rates being zonal in some countries, while in others there are no differentials for distances. Taking the most comparable items we find that in England 10 pounds of any kind of merchandise could be shipped 50 miles by railway express and delivered to the designated consignee for 16 cents; in France a parcel of like weight (5 kilograms or 11 pounds) could be sent any distance by post and delivered for 16 cents; in Germany and Austria the postal rate for parcels up to 11 pounds in weight would be six cents for distances of 46 miles or less, and 12 cents for greater distances, with an additional charge of two and a half cents for delivery in cities and five cents in rural districts. The maximum rate for such a parcel would, therefore, be 17 cents, delivery charge included. The average rates of seven foreign countries for a postal parcel of five kilograms delivered in the first zone (approximately 50 miles) was eight cents; the minimum express rate in the United States was 25 cents for the least weight and distance. Besides being high in cost the express company service is incomplete — deliveries and collections are made only in urban communities. Both defects are irremediable. The rural free delivery system maintained by the government as a public service could not be articulated with an express business conducted for profit by 10 separate private corporations. The 25-cent rate is an irreducible minimum, representing as it does the per parcel expense for way-billing, recording, transcribing bookkeeping and intercorporate accounting between express and railroad — the expense being the same for a one-pound package as for a carload. By the affixment of a postage stamp of the required denomination these economically indefensible and wasteful processes would be eliminated.

The cost of collecting and delivering parcels of 10 pounds and upward in weight, ascertained by express company and mercantile experience, is about five cents. According to postal experience the cost is much less for smaller parcels. The railway mail pay for transportation is one cent per pound for 250 miles, or two cents for 10 pounds for 50 miles. A parcel post rate of eight cents for 11 pounds within a zone of 50 miles (which is the averaged European rate) would, therefore, be quite feasible in the United States. The introduction of zonal rates into the parcel post of this country was strongly combated, but the unfairness to local shippers of flat rates that would be high enough to prevent an enormous postal deficit is self-evident. And, to say nothing of their killing effects on the short-journey traffic, embracing nearly the entire business, such rates would cheat the government on the long journey. A weight limit, if too low, would hinder the free movement of the traffic most in need of the facilities afforded by a parcel post. Express company shipments average 33 pounds in weight; the country merchant deals in lots approximating 100 pounds; in the "farm-to-kitchen" trade a worth-while market basket would not weigh under 50 pounds. The Parcel Post Law, adopted in the form of a rider to the postal appropriations bill of 23 Sept. 1912, embodied a zonal rate system. The rates, however, were made needlessly high — the postage on a 10-pound parcel sent a distance of 50 miles was 32 cents, four times the feasible rate in this country and the averaged foreign rates. The zoning was absurdly complicated by the division of the national area into blocks of 30 miles square. The weight limit was fixed at 11 pounds. Notwithstanding these drawbacks an enormous traffic in small parcels immediately developed. The law contained a provision permitting the Postmaster-General by administrative act, with the concurrence of the Interstate Commerce Commission, to change the rates, zones, weight limit and classification of the parcel mail in such manner as to produce the best results. The weight limit was increased during the summer of 1913 to 20 pounds for all zones and in January 1914 to 50 pounds in the local and first and second zones. These two zones have been consolidated; the zoning has been otherwise simplified and there has been a radical reduction of the scale of rates. An epitome of the present parcel post tariff for the nearer zones follows:

WEIGHT IN POUNDS	Local rate	Zones	
		1 and 2, 150 miles	Zone 3, 150 to 300 miles
1.....	5c	5c	6c
2.....	6	6	8
3.....	6	7	10
4.....	7	8	12
5.....	7	9	14
10.....	10	14	24
20.....	15	24	44
30.....	20	34	weight limit
40.....	25	44	
50.....	30	54	

For the fourth zone the rate is seven cents for one pound and increases four cents with every additional pound; for the fifth zone the initial rate of eight cents increases six cents with each added pound; for the sixth zone it is nine cents for one pound and eight cents for each pound additional; for the seventh zone the rate is 11 cents for one pound and 10 cents added for each pound above that; for the

eighth zone the rate is 12 cents for each pound, which applies to all points more than 1,600 miles from the office of mailing, including Alaska, Hawaii, the Canal Zone, Guam, Tutuila, the Philippines and Shanghai. Zone keys are provided for each mailing office whereby the zone of any office of address can be ascertained without the use of maps.

The domestic parcel post reaches more places than any other transportation agency, and small parcels may be sent long distances at less cost than in any other postal service in the world. The rates for nearby zones are particularly advantageous and encouraging of direct dealings between producer and consumer. Special treatment is accorded to shipments of farm products weighing between 20 and 50 pounds. Parcels may be insured against loss or damage and sent C. O. D. The government will assume liability in the former case up to \$100, the rates being graded from 3 to 25 cents according to the amount of insurance. C. O. D. collections will be made up to \$100. Parcels, furthermore, may be registered, without insurance, for a small fee—a privilege which is taken mostly by mail order houses, but also by others who wish to keep a receipt as a record. On the basis of the latest official reports the number of registered pieces is approximately 37,000,000 in a year; the number insured about 35,000,000, and the number sent C. O. D. about 7,000,000. The C. O. D. collections amount to nearly \$50,000,000 in a year, for which about \$450,000 were received in money order fees. The fees for registration and insurance in 1917 amounted to \$3,237,195. The total weight of parcels handled was about 2,000,000,000 pounds, with an average of about two pounds, and seven cents postage paid per parcel, indicating a postal revenue of about \$70,000,000 from this source.

The first consequence of the institution of the parcel post on the express companies was a drop of about 20 per cent in their annual operating revenues. In its report of 1913 the Interstate Commerce Commission asked to be relieved of its duty to "determine the extent to which the parcel post should supersede the express system," saying, that a proposition to reduce the postal rates might conceivably be destructive of existing companies before adequate provision had been made by the government to take over all of their business. One of the five larger companies discontinued operations on 1 July 1914. Under regulations prescribed by the Interstate Commerce Commission and put in force 1 Feb. 1914, the gross income from express forwarding operations gradually increased and by 1916 was restored to nearly its previous annual normal of about \$100,000,000, the realized net income for the year mentioned having been \$10,614,727. The regulations fixed the forwarding charges on the basis of the most direct route between any two given points; they abolished double rating (for shipments carried over the lines of more than one company) and effected "substantial" reductions (about 8 per cent) in class rates which, of course, did not make them competitive with postal rates. Commodity rates remain at about their previous level. The rules thus prescribed have been adopted by nearly all the States as regulatives

of their intrastate express business, with resulting advantages to both shippers and forwarders, particularly the elimination of the difficulty of quoting the correct rate. The greater part of their operating revenue is now derived by the express companies from transportation, in wholesale quantities, of commodities requiring quick delivery; and this field will be occupied by them permanently unless the government or the railroads themselves should establish an express freight service. While the parcel post absorbed about \$20,000,000 per annum of package express business, it developed three times that amount on its own account; and the potential growth of the parcel post has only begun. What has been witnessed is merely indicative of the enormous volume of traffic that has remained immobile for the lack of means to move it conveniently and at rates which it could bear.

STEPHEN PFEIL.

PARCENARY, in law, is the state or estate of two or more persons, called *parceners*, who hold title, as equal heirs to land, each with a right to a separate share of it, even though undivided. This, of course, carries with it no benefit of survivorship.

PARCHE, one of the small but gorgeous coral-fishes known best as "butterfly-fish" (q.v.).

PARCHIM, a town in Germany, in the republic of Mecklenburg-Schwerin, situated on the Elbe, about 20 miles southeast of Schwerin, on the railway from Ludwigslust to Neubrandenburg. It is an ancient town, founded about 1200, and surrounded by walls in the ancient style, and contains many interesting buildings including its quaint Gothic townhall. It is perhaps best known as the birthplace of Field-Marshal von Moltke, to whom a monument was erected in 1876. Parchim is now a busy industrial town, manufacturing cloth, celluloid, etc., and is one of the richest cities of Mecklenburg, owning much of the surrounding land. Pop. 10,600.

PARCHMENT, a specially prepared animal skin used for several purposes. The ordinary method of treatment of the skin is as follows: It is first fleeced or depilated, then scraped, polished, treated with lime, then stretched and dried. Sometimes it is rubbed down with pumice-stone. Ordinary parchment is made from the skins of sheep, ewes or lambs; the skin of the ewe is more esteemed than that of the sheep, but the lamb-skin is preferred on account of its whiteness as well as being finer. That made from the skins of stillborn lambs is known as "virgin" parchment and closely imitates the quality of vellum. (See VELLUM). For drumheads parchment made from calves or she-goats is usual, that of wolves is preferred; but for kettle-drums parchment of asses-skin is favored. Pigskin specially prepared as parchment is used for covering liturgical books and for sieves. One qualification needed is that the skin be thoroughly freed from grease. As to the origin of parchment, the invention is traditionally said to have been made through Eumenes II wishing to establish a library at Pergamos, but the importation of papyrus from Egypt was made difficult through his having differences with the latter country, so the invention was brought about to supply a substi-

tute, about 190 B.C., and his celebrated library was made up of works written on the skins of goats. Thus the term parchment was probably derived from Pergamos, but the Persians and other Asiatic peoples had been using the skins of animals to write their records on long before this time. Greek authors speak of rolls, or royal *dipters*, of the Persians formed of strips of leather, and the Jews sent a copy of the Scriptures to Ptolemy transcribed on skins; the use is perpetuated by the Jews of copying their sacred books on tanned strips of skins. Pliny says that Cicero declared he saw the entire poem 'Iliad' written on this substance. The Romans termed parchment *charta pergamena*. With the perfection in the art of preparing parchment the most valuable books (*codices*) were made of this medium instead of the former papyrus rolls (*volumina*), though the use of the latter article (see PAPYRUS) remained in use for many years later, on account of its much smaller cost and the facility of procuring it. At the time of Pliny parchment was a dirty yellow tone as the process of whitening it was yet unknown; it was, however, already being tinted in purple to heighten the gold and silver lettering of sumptuous manuscripts. This staining, in the Christian era, was reserved for the sacred books and the usage has continued to modern days. Staining in black also was done for prayer-books. The most ancient manuscripts on parchment date back to the 3d century and the most ancient deeds are not anterior to the end of the 7th century. From that time on parchment displaced papyrus everywhere. From the 5th to the 15th century practically all manuscripts and, from the 8th century, most charters are written on parchment. And with the growth in favor and demand a true industry grew up in its production and workers became known as *pergaminarii*. But this increasing consumption brought also with it inadequate supply and the natural steady increase in price and, in order to economize, less important or antiquated documents were used over again after erasing or washing out the former inscriptions. These parchments utilized a second time are termed *palimpsests*, and, by the use of chemical reagents many extant pieces have had their earlier writing restored sufficiently to be deciphered. Saint Isidor of Seville writes that the first parchment-makers only knew how to make the yellow kind, but later the secret of bleaching was discovered in Rome. But, he says, as it soiled easily and fatigued the eyes besides, this discovery found little success. "Independently of the new secret," he adds, "one distinguishes three sorts of parchment, the white, the yellow and the purple." By the 13th century parchment was the principal substance used in writing in the European centres of learning. It was made in most of the abbeys, but in Paris was the great mart and great sales took place during the Lendit fair opening on the second week in June and held on the Saint Denis plain. At this great sale the university and its members, together with the royal "parcheminiers" had the privilege of first choice in selecting their share, after which the retailers were permitted to supply themselves. The preparation of parchment varied during the Middle Ages according to time and location; that used for manuscripts till the 10th century has generally a high polish and

is very fine and white. Then the quality becomes irregular, being often rough, thick, poorly degreased and transparent. Paper was coming into use (see PAPER) and displacing parchment, and the discovery of the art of printing killed the slower process of calligraphy. By the 15th century we have donats, calendars, Bibles, the Fust and Schöffer Psalterium (1457) generally printed on parchment. Often these are evident imitations (decorative initials and all) made to deceive as written and not impressed in the much cheaper process, for parchment was too expensive in comparison with the now common paper. Parchment codices are generally made up in *gatherings* of four leaves (*quaterniones*) assembled in larger or smaller numbers to make up a book; the format varies also considerably. The roll (*volumen*) form was still used, however, in making up deeds, single sheets being sewn end to end, some to a great length. Parchment in recent years is in very reduced use, chiefly for wills and other deeds and for book-binding and for drums and the friskets of the printers' press. See PAPYRUS; VELLUM; PAPER; MANUSCRIPTS, etc.

Bibliography.—Lalande, J. J., 'Art de Faire le Parchemin' (Paris 1762); Leist, 'Urkundenlehre' (Leipzig 1893); Peignot, E. G., 'Essai sur l'Histoire du Parchemin et du Velin' (Paris 1812); Wattenbach, W., 'Schriftwesen im Mittelalter' (Leipzig 1896).

CLEMENT W. COUMBE.

PARCHMENT, Vegetable, a substance first introduced in 1853. It is made by dipping ordinary unsized paper for a few seconds in concentrated sulphuric acid mixed with one-half its volume of water and then quickly removing all trace of the acid. The mixture is allowed to cool before being used. This simple treatment produces a remarkable change in the paper. It acquires a parchment-like texture; turns translucent, especially when thin; and becomes about five times stronger than ordinary paper. Vegetable parchment is also impervious to water, but is rendered soft and limp when dipped into it. A solution of chloride of zinc acts on paper in a similar way. In the manufacture of vegetable parchment a roll of paper is by a mechanical arrangement pulled through a vat containing the sulphuric acid (the time of immersion being from 5 to 10 seconds for thin paper), next through water, then through a weak solution of ammonia, and once more through water. It is afterward passed through felt-covered rollers, and then calendered. In recent years it has come into general use as a sanitary covering for bread, and other foods, both prepared and semi-prepared, candies, etc.

PARDEE, George Cooper, American physician and political leader: b. San Francisco, Cal., 25 July 1857. He was educated at the University of California, at the Cooper Medical College, and at the University of Leipzig, Germany. In 1885 he returned to California from abroad, began the practice of medicine as an eye and ear specialist, and was soon recognized as one of the leaders of his profession. He was also active in public life, was a member of the Oakland board of health and city council, and carried on a vigorous and successful campaign in behalf of pure water and against the licensing of poolroom gambling. In 1893

a reform movement in city politics was organized and he was elected mayor for two years; in this office he compelled the corporation owning the waterworks to reduce its high charges, and dealt with the railroad strike of 1894. In 1898 he was a candidate for the Republican nomination for governor, but was not nominated, and in 1900 was a delegate to the Republican National Convention. In 1899 he was appointed a regent of the University of California. In 1902 he obtained the Republican nomination for governor, and after a vigorous campaign was elected; the most important opposition to his election came from the labor element on account of his action during the strike of 1894. He served as governor until 1907. He was a member of the National Conservation Commission 1907-09, and was appointed chairman of the Conservation Commission of California in 1911. He was a delegate to the Progressive National Convention in 1912, and was a presidential elector in the same year.

PARDO, pâr'dô, **Manuel**, Peruvian statesman: b. Lima, Peru, 12 Aug. 1834; d. there, 16 Nov. 1878. He was educated in Chile and in Europe, paying much attention to the study of law and political economy. For a time he was in government employ, then retired to private life, but in 1865 was appointed secretary of the treasury by President Prado, which office he filled with great ability. In 1869 he was elected mayor of Lima and in 1872 was elected to the presidency. His inauguration was opposed by Tomas Gutierrez, the minister of war under President Balta, who dissolved congress, imprisoned Balta and declared himself dictator. Pardo was compelled to flee, but when the dictator was killed in an uprising of the populace he returned and took the office 2 Aug. 1872, the first civilian President of Peru. His administration was one of great benefit to the country. He improved the financial condition of the country, aided the advancement of science and literature, crushed a rebellion in Moquegua and upon the expiration of his term of office in 1876 prepared to retire from public life, but was elected to the senate, of which body he was president when assassinated in 1878. His death was mourned as a national calamity.

PARDO-BAZÁN, pâr'dô-bâ-thân', **Emilia**, Spanish novelist and critic: b. La Coruña, Galicia, 1852; d. Madrid, 12 May 1921. In 1891 she established a critical review, 'Nuevo Teatro Critico.' Her literary reputation in Spain was won by her works of fiction, generally classed as naturalistic, most satisfactory in picturesque delineations of Galician landscapes and manners. Among them are 'Los pazos de Ulloa'; 'La piedra angular'; 'Pascual López'; the collection of short stories, 'Cuentos de Marineda'—Marineda being La Coruña—; 'Una Cristiana'; and its sequel, 'La Prueba.' Among her critical writings is a prize essay, 'Estudio de las Obras del Feijóo'; 'San Francisco de Asis,' and 'La revolución y la novela en Rusia.' The descriptive volumes, 'Mi romería' and 'De mi tierra,' contain patriotic views of local scenes. She was the author of five plays.

PARDON, remission, by official act, of the penalty of crime; also the document granting such pardon. The custom dates from remote antiquity, and was usually exercised by the sovereign only. In England the king has sole

power to pardon, but there are legal restrictions attached to its exercise. By power granted by the Constitution of the United States, the President may pardon all Federal offenses except impeachment.

Many reasons for giving this power to sovereigns and other chief executives have been assigned, among which may be mentioned the following: As a reward for actual reform of the criminal while in prison and for good conduct there, to mitigate the harshness of laws in their application to particular cases, the probability or possibility of the innocence of the accused person, for reasons of state, etc.

Offenses against the various States in this country are pardoned by official acts of such States, generally by the governors thereof. In some States pardons are granted by pardoning boards, and in others concurrence by the legislature is necessary.

The President of the United States may pardon before indictment or conviction, and his power to pardon, within constitutional limits, cannot be modified by legislation.

A pardon may be absolute or given on condition precedent or subsequent, and it may be merely a commutation of punishment. A condition precedent must be performed before the pardon takes effect, and a breach of a condition subsequent annuls the pardon, with the effect that the prisoner may be compelled to serve his full term, after a hearing before a court which decides whether he has violated the condition. Usually an absolute pardon effects a removal of all legal disabilities, but forfeited property or fines are never returned. A pardon secured through fraud or deception is void. Pardons are usually sought by means of petitions, together with affidavits and letters of persons stating the grounds upon which leniency is asked.

PARDOW, pâr'dô, **William O'Brien**, American Jesuit priest: b. New York, 1847; d. 1909. In 1864 he was graduated at the College of Saint Francis Xavier, and subsequently studied at Woodstock College, Md., and in France. In 1891 he was president of the College of Saint Francis Xavier, New York; was provincial superior of the New York and Maryland province of his order in 1893; assistant at Saint Ignatius Loyola, New York, in 1901-03; lecturer at the Jesuit Institute in 1903-06; and assistant at the Gesu, Philadelphia, in 1906-09. He was a very eloquent preacher, by many considered the foremost of his time, and was also prominently identified with the Modernist movement.

PARÉ, pâ-râ, **Ambroise**, French surgeon: b. Bourg Hersent, near Laval, department of Mayenne, 1517; d. Paris, 20 Dec. 1590. He studied in Paris and in 1536 attached himself as surgeon to the army destined to serve in Italy under Marshal René de Montejean. In 1542 he accompanied the Viscount de Rohan during his campaign at Perpignan. In 1552 he became surgeon to Henry II, under whose successors (Francis II, Charles IX and Henry III), he held the same post. His enemies were numerous among the physicians, who accused him of having poisoned Francis II. It was formerly believed that Paré was a Protestant, and that he was saved from the massacre of Saint Bartholomew by Charles IX, but M. P. Valet

has proved that he was a Catholic. He introduced improvements in the treatment of gunshot wounds, in the operation of trepanning, and in amputation. He also introduced or restored the practice of tying up divided arteries and operated on articular concretions. A noteworthy edition of his works was produced by Malgaigne in 1840-41. See the 'Life' by Paulmier (1884), and Paget, 'Ambroise Paré and his Times' (1897).

PAREGORIC (Greek, *παρηγορικός*, soothing) an opiate, the camphorated tincture of opium. It is composed of opium, benzoic acid, camphor, oil of anise, honey and dilute alcohol. Every fluid ounce contains two grains each of the opium, acid and camphor and two minims of oil of anise. It is an anodyne and antispasmodic and is much used to allay cough, relieve pain in the stomach and intestines, and to induce sleep. Many parents rely on this preparation to quiet young children and relieve pain in the stomach; but great harm results from too frequent doses because of the susceptibility of young children to opium. Though a comparatively weak preparation of opium, if given repeatedly or in a large dose it may act as a poison.

PARIASAURUS, or **PARIASAURUS**, a genus of extinct reptiles. See **THEROMORPHA**.

PAREJA, Juan de, hoo-än' dā pä-rā'hā, familiarly called "El Esclavo," Spanish painter: b. Seville, 1606; d. Madrid, 1670. He had, while a mere boy, been purchased by the painter Velasquez as a slave and was of Moorish parentage. Constantly employed in the painting-room of Velasquez, whom he had accompanied to Madrid in 1623, he became inspired with a passion for painting and secretly copied the works of his master whom he accompanied to Italy, taking every opportunity of perfecting himself in his art. As Philip IV was in the habit of visiting the studio of Velasquez and turning every picture the face of which was to the wall, he one day turned a picture which Pareja had completed with great care and placed in the king's way. When the king asked who the painter of the work was, Pareja fell on his knees and asked Philip to protect him. "Such a painter as that," replied the monarch as he turned to Velasquez, "ought not to be a slave." Velasquez gave the newly found artist a deed of manumission and took him to be his pupil. A fine portrait of Pareja by Velasquez is shown in the collection of the Earl of Radnor. Pareja's 'Calling of Saint Matthew' (1661) is in the Prado Gallery at Madrid, and in the Hermitage at Saint Petersburg is a very beautiful portrait by him. In the chapel of the Recolects at Madrid is his 'Saint John the Evangelist, Orontius and the Madonna'; and the 'Baptist, of Christ' is in the Santa Trinidad at Toledo. These pictures exhibit him not only as a learned and skillful disciple of his master, Velasquez, but as very much of a genius in his own way who has much of the style of the best schools of Genoa and Venice in his work, which shows, at times, a strong reflection of the Flemish masters. While his early work was purely imitative, he became later in life as cosmopolitan as his master, with whom he traveled constantly and thus had a chance to study the best in art. His conception and coloring are little inferior to those of Velasquez.

PARILLA, a name given to some of those crustaceous lichens of commercial value which are used to produce archil, cudbear and litmus. The name more strictly belongs to one species, *Lecanora parilla*, and the red or crimson dye prepared from it. See **ARCHIL**.

PARENCHYMA, in anatomy, zoology and botany, the soft tissue of organs: in anatomy it signifies the true tissue as distinct from connective tissue; in zoology it is generally applied to that of open tissue, as of the lungs and liver; in botany to the substance of leaves, as the green "palisade-parenchyma" of the upper surface of a leaf, or the "spongy parenchyma" of the lower surface. The characteristic feature of parenchyma of plants is that the cellular tissue is shallower and encloses intercellular spaces; whereas in prosenchyma it is deeper and without cellular interspaces. See **TISSUE**; **LEAVES**.

PARENT, pa'rän', Etienne, Canadian journalist and cabinet officer: b. Beauport, near Quebec, 2 May 1801; d. Ottawa, 23 Dec. 1874. He was educated at the Seminary of Quebec and at the College of Nicolet. At 21 he became editor of *Le Canadien*, an old and influential journal published in French, which position he resigned in 1825 in order to study law. He was called to the bar in 1828, but practised for only a brief period, becoming translator, and subsequently librarian, of the legislative Assembly of Lower Canada. He again edited *Le Canadien* in 1831-42, suffering imprisonment in 1837-38 because of political opinions published in his newspaper. Upon the union of Upper and Lower Canada into one province in 1841, Parent was elected to its assembly from Saguenay; but in 1842 he resigned in order to accept an appointment as clerk of the executive council. In 1847-67 he was assistant secretary for Lower Canada, and in 1867 he was appointed Acting Assistant Secretary of State for Canada. Throughout his career he continued to write for *Le Canadien*, bringing effective support to the French-Canadian party. He was deeply interested in the improvement of industrial conditions and an advocate of political and religious reforms. He was a lecturer of repute and did much to popularize that form of instruction in Canada. Author of 'Du travail chez l'homme,' 'L'Industrie comme moyen de conserver notre nationalité,' and 'Importance de l'étude de l'économie politique,' published in 'Repertoire Nationale' (1848); 'De l'importance et des devoirs du commerce' (1852); 'Considérations sur le sort des classes ouvrières' (1852), etc.

PARENT, Simon Napoleon, Canadian statesman: b. Beaufort, Quebec, 12 Sept. 1855; d. 7 Sept. 1920. He was graduated at Laval University in 1881 and was called to the bar in that year. He engaged in practice in Quebec, attaining eminence in his profession. He served on the municipal council of Quebec in 1890-94, and was mayor of that city in 1894-1906. In 1890-1905 he represented Saint-Sauveur in the legislative assembly of Quebec; was Minister of Lands, Forests and Fisheries in 1897-1900, and from 1900 until he retired from public life in 1905 he was Prime Minister of Quebec. He became chairman of the Transcontinental Railway of Canada in 1905.

PARENT AND CHILD. See **LAW OF FAMILY.**

PARENT-TEACHER ASSOCIATIONS.

Associations of parents and teachers came into being as a co-operative agency between the parents and the public school. The need for such associations is due to parental ignorance of educational procedure; to parental indulgence of childhood weaknesses to the injury of the children; to the teachers' ignorance of child development; and to the lack of authority by school officials to compel obedience. By a common association the attention is focussed on the child and his educational problems. The parent becomes acquainted with the difficulties besetting the teacher by seeing the school activities and by following his child into his place in the school organization. In so far as the parent can comprehend, he is made to see the educational process applied to his child and his sympathetic interest is elicited. The teacher learns the mental and moral characteristics of the parental antecedents of the child and makes contact with the home atmosphere. The teacher by getting a sympathetic understanding of the child's homelife, gets a clearer knowledge of the child's mental habits and capacities. The clearer point of view by both parent and teacher sheds light on problems of school discipline and removes obstacles in the child's relations to school authorities.

A parent-teacher association usually consists of all the parents who send their children to the same public school building, and all the teachers who teach in that building. An association may be formed of all the parents and teachers of an entire community. If the community is large, with more than three school buildings, building associations give better results than community associations. A central association composed of the building associations is sometimes found profitable. The organization is simple, needing no more officers than are necessary to conduct meetings, arrange programs, receive and expend small sums of money. Since education is the fundamental purpose it is necessary that the principal or superintendent be the guiding spirit of the association. When the parents become the leading element in the association, the purposes of the association will frequently become social or even political to the neglect of the child's educational interests.

The activities of parent-teacher associations start properly and effectively with exhibitions of school work to which the parents are invited. From the school exhibit the parents enter intelligently into the school's problems. Methods of teaching particular subjects may be presented. Special activities such as playgrounds or community dances may be explained. Important phases of child life may be presented. Many parents as well as children are poorly acquainted with the difficult period of adolescence. Vocational guidance can be made clear to parents and children. Home study, an ever-vexatious question, may be adjusted. Home social diversions may be restricted and guided. A school library may be started or augmented by the association. School equipment may be improved by laying right foundations in parental intelligence and interest. New school-houses may be secured. Right sanitation may

be established. All the legitimate interests of the child and the school are promoted by a right use of a parent-teacher association.

The education of the American parent is an important part of our educational problem. The immigrant parent is our chief concern but by no means our only concern. Parents often lose control of their children because they cannot intelligently follow the studies of their children in school. The child who finds that his excursions into algebra of Latin or biology carry him beyond the range of his parents' achievements may lose respect for his parents. Membership in a school social organization may set up a false sense of importance and independence in the child. The child's ambitions may reach out beyond the limits of the parents' vision. How to educate the parent up to the child is no mean question. How to help the father and mother understand the first three of the seven "ages of man" is a large undertaking. The parent-teacher association offers an organized scheme for this education of the parent and will show much common ground between parent and teacher. It will help the parent better to know his own child. See **EDUCATION, ELEMENTARY.**

A. R. BRUBACHER,

President of New York State College for Teachers.

PAREPA-ROSA, pā-rā'pā-rō'sā, **Euphrosyne Parepa de Boyesku**, British opera singer: b. Edinburgh, Scotland, 7 May 1836; d. London, England, 21 Jan. 1874. She was the daughter of Georgiades de Boyesku, a Wallachian nobleman, and was educated by her mother. In 1855, she made a successful début at Malta where she appeared under the stage name of Parepa, and in England the following year. She possessed a soprano voice of remarkable power, and sang in the title-roles of 'Camille,' 'La Reine Topaz,' 'Victorine' and other operas, with great success. She was married in 1864 to an English army officer, Henry de Wolfe Carvel, who died the next year. In 1866 she made her first tour of America and in 1867 was married to Carl Rosa, a noted violinist, operatic manager and conductor with whom she formed the Parepa-Rosa Company. Her success continued unbroken until her death, which occurred while she was preparing her part in an English version of 'Lohengrin.' She excelled in oratorio.

PARESIS. See **GENERAL PARESIS; INSANITY.**

PARHELION, in astronomy, a mock sun, having the appearance of the sun itself, and seen by the side of that luminary. Parhelia are sometimes double, sometimes triple and sometimes more numerous. They appear at the same height above the horizon as the true sun, and they are always connected with one another by a white circle known as the parhelic circle. This circle is due to the reflection of the sun's rays by the vertical faces of ice-crystals in the air, which assume a definite orientation in falling. The parhelia appear where the parhelic circle crosses and reinforces the two halo circles around the sun at distance of 22° and 46° respectively. The halos show the colors of the rainbow with the red inside. They are due to the fact that 22° and 46° are approximately the

angles of least dispersion, and hence of the greatest transmission of light, for ice prisms with angles of 60° and 90° respectively. Very rarely parhelion-like concentrations of the parhelic circle are observed at 180° or 120° from the sun. These are known as anethla or paranethelia, respectively. See HALO.

PARIA, pā-rē-ā or pā-rē-ā', (1) gulf of the Atlantic between Trinidad and Venezuela and almost hemmed in by land, being connected with the ocean by the Boca de Dragos or Dragon's Mouth, at the north, and by the Boca del Soldado or Soldier's Mouth, at the south. These straits are about 10 miles wide, are very dangerous and were first sailed through and named by Columbus in 1498. The gulf (sometimes called Golfo Triste) furnishes good anchorage. It measures 100 miles in length and 40 in width, receives the northern waters of the Orinoco as well as the Colorado, and is full of fish. (2) A peninsula, jutting to the east from the mainland and forming the northern side of the Gulf of Paria. It is formed by a bold picturesque ridge of mountains. (3) The extreme eastern point of this peninsula is called the Cape of Paria (or Punta Panas).

PARIAH, pā-rī-ā, a low class of Hindus in the Tamil country in Madras. They belong to the class of agricultural laborers and are commonly employed as servants by Europeans. They are avoided as unclean by all castes professing Brahmanism, yet are superior to some other castes in the Tamil country. The name is derived from *parai*, a large drum, the Paraiyans being the hereditary drumbeaters at festivals and similar occasions. The caste numbers nearly two and a half millions. It corresponds to the Malas in the Telegu country. The Holeyas in the Kanarese country and the Mahars in the Deccan. They performed notable service under Chie, their numbers furnishing a large proportion of the sepoys, and many of them are in the Madras Miners and Sappers branch of the service. Many of them have distinguished themselves by ability after being educated, their intelligence being decidedly normal. The word has come into common use in English as descriptive of any class degraded socially. Consult Lapique, L., *Le problème anthropologique des Parias et des caste homologues, chez les Dravidiens* in 'Bulletin de la Société d'Anthropologie de Paris' (Vol. VI, 1905).

PARIAH DOG, one of those dogs which are masterless and run wild in many Oriental cities. The name is derived from that given to the outcast or lowest servant class in India where, as also in Constantinople and other cities, such dogs are extremely numerous. In many cities they form almost a distinct breed, being of large size and generally of a dirty yellow or blackish color. The hair is short and smooth, and the ears pointed and erect. They possess the canine instinct of running in packs and frequently take possession of certain districts after nightfall. A very useful service is performed by them in Constantinople, where they act as scavengers and devour the garbage which is not otherwise removed. Their wits have been sharpened by this precarious mode of life and they are said to be possessed of unusual intelligence and cunning. By the Mohammedans they are considered unclean and the faithful are defiled

by accidental contact with one of them. Pariah dogs fall into five classes, namely, (1) A wild breed of a reddish-brown color inhabiting the lower ranges and jungles of the Himalayas; (2) those inhabiting districts in which turnspits are frequently met with; (3) those of Sumatra which are distinguished by their fox-like appearance and their bushy pendulous tail; (4) the indigenous Javanese animal. (5) To these should be added the Egyptian dog already mentioned, which seems to be in many ways distinct from the other four classes.

PARIAN CHRONICLE. See ARUNDEL MARBLES.

PARIAN MARBLE, the most celebrated statuary marble of antiquity. It is white, of mellow tone, and large-grained. It received its name from the island of Paros (q.v.), where it was quarried. See MARBLE.

PARIMA, pā-re'ma, *Sierra de Sierra*, mountain range of Guiana, Venezuela and Brazil. The eastern end of the range is known locally as the Sierra Pacaraima. This range of mountain forms an extensive, irregular upland plateau sloping toward the valley of the Amazon and to the right and left of it. The Orinoco flows on three sides of the range, which has as its southwestern boundary the Rio Negro and reaches east to the Essequibo. A bare plateau it is with old sandstone superficial strata and a granite core. The range reaches its highest points in Sierra Maraguaca, Duida and Yamari, which are over 7,000 (the first two over 8,000) feet high. The roughest and most defined part of the Parima range is that which extends into Venezuela.

PARINI, Giuseppe, joo-sép'pē pā-rē'nē, Italian poet: b. Bosisio, a village of the Milanese, 23 May 1729; d. Milan, 15 Aug. 1799. He studied theology and was ordained a priest in 1754. His interests were always literary, rather than ecclesiastical. He was an instructor successively in the Scuole Palatine and the Brera College, at Milan, and held office for three years in the city government under Napoleon. His chief work is 'Il Giorno' ('The Day'), a biting satire on the Italian nobility. He wrote also some excellent odes, and was always most skillful in the arts of versification. There is an edition of the 'Giorno' by Borgognoni (1892). Consult Dumas, 'Parini, Sa Vie ses Oeuvres son Temps' (1878); Cantu, 'L'Abate Parini' (1891); Cerquetti, 'Il testo più sicuro delle Odi di Giuseppe Parini' (Osimo 1892).

PARIS, or **ALEXANDER**, was the second son of Priam, king of Troy and Hecuba, and is set forth in Homer as the cause of the Trojan War. Before his birth his mother dreamed that she had brought forth a fire-brand, which reduced Ilion to ashes, and Priam, learning this, gave her next son to be exposed by a shepherd on Mount Ida. Here the babe was suckled by a she-bear and the shepherd discovering this after five days, gave him the name of Paris, and undertook his rearing. The name of Alexander was given him later for his valiant defense of certain heroes. On Mount Ida he fell in love with the nymph Enone, daughter of a river god. Their happiness was interrupted one day by the appearance of Hermes leading before Paris the three goddesses Hera, Athene and Aphrodite. At the bridal of Peleus and Thetis,

Eris, or Ate, goddess of strife or mischief, had thrown down a golden apple on which was inscribed "to the fairest woman." Hermes called upon Paris to decide which of the three goddesses present was entitled to the gift, for each of the three claimed it as hers by right. Hera promised to the beautiful shepherd power and dominion if he would decide in her favor; Athene offered fame and wisdom; Aphrodite pledged herself to send him the loveliest wife in the world. The judgment of Paris was made in favor of the goddess of love, and when he one day brought a bullock for sacrifice at a festival in the city of Troy, he was recognized by his sister, Cassandra, the prophetess, and acknowledged by Priam as his son. With the aid of Aphrodite he carried off Helen, the beautiful wife of Menelaus, king of Lacedæmon, and returned with her to Troy. This was the cause of the Trojan War, for Agamemnon joined his brother Menelaus in a campaign in which Troy was besieged for 10 years and eventually sacked. Homer has given us vivid ideas of the beauty of Paris and has described him as fond of minstrels and of beautiful women, as well as skilful in war. His lightness of character is also dwelt upon by the poet. After the fall of Troy, he returned to Mount Ida and the nymph Enone to be healed of the wound he had received from the arrow of Hercules shot from the bow of Philoctetes. But Enone repulsed her faithless lover, who died of his wound. In Greek art he is represented as a beardless young man of handsome form, wearing a Phrygian cap, and generally seated with the apple in his hand as in the statue by Euphranor in the Vatican. The Judgment of Paris is the subject of vase paintings. See *ILIAD*; *HOMER*; *TROJAN WAR*.

PARIS, pă-rēs, **Gaston Bruno Paulin**, French philologist: b. Avenay (Marne), 9 Aug. 1839; d. Cannes, 6 March 1903. He was son of a noted father Paulin Paris (q.v.). In 1872 he became professor of French language and literature at the Collège de France, succeeding his father, and in 1895 director of that institution. In 1896 he was elected to the academy. A pupil at Bonn of Diez, he did much to carry forward the study of Romance philology which the former had practically founded. He and Paul Meyer founded *Romania*, a romance journal. He was one of the greatest of French critics and a very profound and able philologist. His knowledge was wide as his preparation had been deep. He devoted himself principally to the language and literature of his own country, and he used all his efforts to arouse in his pupils a love and appreciation of the best in literature. 'A Poetical History of Charlemagne' (1866); 'Poetry of the Middle Ages' (1885); and 'French Mediæval Literature' (1888), are his most important publications.

PARIS, pă-rē, **Louis Albert Philippe D'Orléans, COMTE DE**, French nobleman, grandson of Louis-Philippe: b. Paris, 24 Aug. 1838; d. Stowe House, Buckinghamshire, England, 8 Sept. 1894. His father was killed by an accident in 1842, leaving him heir to the French throne. After the revolution of 1848 he resided for a time at Claremont Park, Surrey, where he was educated by his mother, and where Louis-Philippe died in 1850. He made a journey to Syria in 1859 in company with his brother, the

Duc de Chartres, and on his return to England he published an account of the journey under the title of 'Damas et le Libeau.' In 1861, during the American Civil War, he, with his brother, the Duc de Chartres, served as volunteers in the Union army in order to gain a practical knowledge of military affairs, and were for some time on the staff of General McClellan. On his return to Europe in 1862 he married his cousin, the Princess Marie-Isabelle, eldest daughter of the Duc de Montpensier. Under a nom de plume he began about this time to contribute to the *Revue des deux Mondes*. On the outbreak of the Franco-German War he desired to serve against the enemies of France, but was not allowed by the French authorities to do so. After the war, however, he was admitted a member of the first national assembly, and his property was restored to him. On the death of the Comte de Chambord, in 1883, the Comte de Paris was recognized as head of the royal house of France. Under the expulsion bill of 1886—a measure due to the fear of the French republicans that the royalist party was becoming too strong—he, and the other royal princes, were forbidden to reside in or enter France. The same year his eldest daughter was married to the crown-prince of Portugal. He published a valued 'Histoire de la Guerre Civile en Amérique (1874-75)', which has appeared in an English translation; and 'De la Situation des Ouvriers en Angleterre' (1864). During his latter years he lived the retired life of an English nobleman.

PARIS, pār'is, **Matthew**, English mediæval historian: b. about 1200; d. about 1259. He entered the Benedictine order at the monastery of Saint Alban's in 1217, and on the death of Roger of Wendover in 1236 succeeded to the post of historiographer and began the continuation of the 'Chronica Majora,' a record of English history kept at the monastery. In 1246 he was invited by Hacon IV of Norway to adjust the affairs of the abbey of Saint Benet Holm in Trondhjem province, and in 1248-49 thoroughly reorganized the establishment and received extensive gifts from the monarch. His great chronicle ends abruptly at May 1259. He carefully revised the work of the early compilers on the 'Chronica,' extending to the end of 1188, and the contribution of Wendover (1189-1235) and prepared an abridgment called the 'Historia Minor' (1067-1253). His narrative is extremely accurate; he wrote brightly and with vigor, noted important happenings of foreign lands, and did not spare his censure when he thought it needed. Paris also prepared an abridgment of the 'Chronica Majora' covering the period 1067-1253 which contains a few incidents not recorded in the larger work; and he wrote the 'Vitæ Abbatum S. Albani.' Consult Gross, C., 'Sources and Literature of English History' (London 1900); Jessopp, A., 'Studies of a Recluse' (London 1893); Plehn, Hans, 'Politische Charakter Matheus Parisiensis' (Leipzig 1897); Potthast, A., 'Bibliotheca Historica Medii Ævi' (Vol. II, Berlin 1896).

PARIS, Paulin, French philologist and historian: b. Avenay, Marne, 1800; d. Paris, 1881. He became an assistant in the manuscript department of the National Library, and an expert in the decipherment of old French literature,

his work marked by ceaseless energy, good taste and a pleasing style, extending over 50 years. He was elected a member of the Academy of Inscriptions in 1837 and from 1853-72 was professor of mediæval history in the Collège de France, where he was succeeded on his retirement by his eminent son Gaston Paris (q.v.). His principal works are the catalogue of 'Manuscripts français de la bibliothèque du roi' (1836-48); and his edition of the 'Grandes chroniques de France' (1836-40). Among his numerous other works are notable selections from manuscripts, 'Romancero français,' 'Garin le Loherain,' 'Berte aus grans piés,' 'Romans de la table ronde' and a French translation of Byron (1830-36).

PARIS, pār'is (Fr. pā-rē), the capital and chief city of France, and the political, literary, artistic and social capital of Europe since the decline of Rome, situated in the northern part of France, on both banks of the Seine, in lat. 48° 50' N. and long. 0° 00' Observatoire. It is the second city in size in Europe, and the third centre of population on the earth, being surpassed only by New York and London. The population, according to the census of 1911, is as follows: Paris, within the walls, 2,888,110; the Northern and Southern suburbs, 1,265,932; total for Greater Paris, 4,154,042. This is the department of the Seine, with an area of about 184 square miles. To this should be added half the population of the department of Seine et Oise, 458,808, which gives a grand total of 4,562,850 for Paris and the suburbs. It is the only considerable modern city which is completely surrounded by a wall, and the population, in consequence of the confined area within the fortifications (about 31 square miles), is the densest in Europe. The following table gives the population at various times since the early part of the 13th century, before which no accurate census is found:

In 1220, under Philippe Auguste.....	120,000
In 1250, under Louis IX.....	130,000
In 1380, under Charles V.....	150,000
In 1605, under Henry IV.....	200,000
In 1715, under Louis XIV.....	500,000
In 1810, under Napoleon.....	600,000
In 1831, under Louis Philippe.....	786,000
In 1851, under the Second Republic.....	1,053,000
In 1861, after the annexation of the faubourgs within the fortifications.....	1,696,000
In 1866, under Napoleon III.....	1,825,000
In 1876.....	1,988,800
In 1886.....	2,344,000

For a thousand years prior to about the middle of the last century Paris was the largest city in the world. The defense of this metropolis is provided for by an elaborate system of fortifications, which were constructed between 1840 and 1845, at an expense of 140,000,000 francs. The enceinte, with its 94 bastions, is about 22 miles in length. The ramparts, averaging 32 feet in height, with a parapet 19 feet in width, are environed by a moat 48 feet in width, and a glacis. The approaches to the city are also commanded by 17 detached forts at different but relatively short distances from the walls. A second line of forts at a greater distance from the ramparts has also been constructed on the heights commanding the valley of the Seine. The area included within this elaborate system of fortifications is 400 square miles. The garrison in time of peace numbers 50,000 men. Thus Paris is the greatest fortified

camp in the world. But the experience of the late war has shown that fortifications, even the most elaborate, are of little value against modern artillery; the only real defense for the great city is the army. The administration of the city is shared between the Prefect of the Seine, appointed by the Minister of the Interior, and the municipal council elected for a term of three years—one from each *quartier*—by universal suffrage. The annual budget runs to 375 or 400 millions of francs. The city is divided into 20 *arrondissements*, in each of which there is a mayor and a *mairie*, which is the office of the mayor, and constitutes a sort of city-hall for the *arrondissement*. Each of the *arrondissements* is divided into *quartiers* corresponding roughly to the wards of an American city. With 20 *arrondissements* there are 80 of these *quartiers*, each one of which has a distinguishing name, as for example, the quarter of the Champs Elysées in the eighth *arrondissement*, or the quarter of the Sorbonne in the fifth *arrondissement*. These quarters are in general of about the same territorial extent, but the population varies greatly between about 10,000 and 110,000.

Early History.—Our knowledge of Paris and its people begins during the Roman invasion of Gaul, in the spring of the year 53 B.C., at which time Julius Cæsar convoked at Lutetia an assembly of the Gallic tribes. This is the first mention of what is now Paris in authentic history. Its annals thus commence in the 'Commentaries' of Cæsar, wherein, referring to that assembly, he mentions a collection of fishermen's huts on the island in the Seine, which he calls Lutetia—probably and perhaps certainly a Latinized form of the name by which it was then locally known. Strabo writes it *Lucotocia*, and Ptolemy *Lucotecia*, while the Emperor Julian dates a letter from the city calling it *Louchetia*. Of these various spellings, that employed by Cæsar is the one commonly adopted, although the hill of the university was known for many centuries as '*Mons Lucotitius*.' In modern French it is written *Lutèce*, and is understood to refer only to the island of the city, while *Lucotèce* is the French name for the Roman settlement on the left bank. The derivation of the word has been the subject of much research. Scholars have attempted to trace it to Celtic sources, especially to the dialect of lower Brittany. Cæsar in the 'Commentaries' states that the inhabitants of the island in the Seine to which he refers formed a division of a clan or tribe, called the *Parisii*. Thus, he says, 'The *Parisii* are inhabitants of a tract bordering upon that of the Senones, with whom tradition says they were once allied.' In the year 52 B.C., Labienus, the lieutenant of Cæsar, marched upon Lutetia, and after a battle fought with the *Parisii* in the plain now covered by the southern suburbs, and of which an echo remains to this day in the name of the little village of Vitry (place of the victory) took formal possession of the island on behalf of the Romans. The etymology of the term *Parisii* has been no less a subject of dispute than that of Lutetia. It is, however, also traced to lower Brittany and to a Celtic word signifying a boat. The ancient, as well as the modern, emblem of Paris is a boat, as may be seen by the interesting carving which ornaments the base of one of the

vaults of the roof in the Palais des Thermes. Thus the figure of a ship which serves everywhere to identify the property of the city of Paris to-day, and which constitutes the hall-mark, so to speak, of the city, harks back to the *Parisii* of Cæsar and his 'Commentaries.' Hilaire Belloc says, "The triple prows which are seen on the lamp-posts of modern Paris are an emblem 1,500 years old, and without a break of continuity." The Romans occupied Paris for

Paris under the Romans.

more than 500 years. Extensive remains of their domination are still found on the left bank, notably the Palais des Thermes at the Musée de Cluny, the amphitheatre, just out of the rue Monge, the arches of the aqueduct which crosses the valley of the Bièvre at Arcueil—two of the arcades of which are preserved to this day, just outside the southern wall—and the ruins of the reservoir connected with it which were discovered in opening the rue Gay-Lussac.

Topography.—A modern traveler looking over the town from the heights of Montmartre, from the top of the Eiffel Tower or from the dome of the Pantheon, sees the city spread out before him like a map, lying in a plain encircled on almost every side by distant and low hills, those on the north and east being farther removed than those on the south and west. Paris, therefore, is situated in what geologists call a basin or plain of greater extent than that occupied by any other modern capital, being scarcely ever less than 20 miles in diameter and in some places much more. The Seine enters this plain at the southeast corner, coming from the highlands of Burgundy and Champagne, and, describing a great arch or bow through the city, passes off and out at the southwestern corner of the plain.

On the west rises Mont Valérien, and on the north the hillocks of Enghien and Montmorency; the hill of the university or Mont Sainte Geneviève on the one hand, and the somewhat more conspicuous eminence of Montmartre on the other rising out of the plain. Paris naturally divides itself into the Cité, the University, or the left bank, and the Ville, or the right bank, and to be understood it must be looked at from these three points of view. Originally the town was all on the island, but even in the days of the Romans villas and country seats were built on either bank, especially on the north bank up toward the heights of Montmartre, while on the south bank the Romans fixed their camp and at the same time the emperor's palace. We note that Julian the Apostate, who resided much of the time at Lutetia—which began about this time to be called Paris—was crowned emperor of Rome in the year 361 A.D., at a spot in the camp on the left bank, which is now located in or near the boulevard Saint Michel, between the boulevard Saint German and the Luxembourg. Julian was very fond of Paris, referring to it in one of his letters as "*ma chère Lutèce*" (so writes with charming naïveté an ancient chronicler of the town), and praising it for its vineyards, its mild climate, the figs and the white grapes (which we still have) that the farmers of the suburbs fur-

Paris under Philippe Auguste.

nished for his table, saying that Bacchus is the god of the Parisians because he is the father of joy. By the time of Philippe Auguste the city had extended on the right bank as far down the river as to what is now the eastern façade of the Louvre, the foundation stones of which were laid by that monarch in the year 1223. The wall of Philippe Auguste extended from his palace of the Louvre in a wide loop northward and eastward to a point about the middle

of the island of Saint Louis, as it now exists, and thence, across the river, in a smaller loop which crossed the rue Soufflot at the corner of the rue Saint Jacques, and passed near what is now the garden of the Luxembourg and close to Saint Germain des Prés, to a point on the river at the Tour de Nesle about on the site of the Institute. Great chains were hung across the river above and below to complete the fortification, and towers at either end buttressed the river. A fragment of the wall of Philippe Auguste still stands in a good state of preservation at a point in the rue Clovis near the rue Cardinal Lemoine, just behind the Pantheon, and some less important traces of it are also still to be found on the right bank. Like most river cities, Paris grew down the river rather than up. The size of the city within the walls was increased by the mural enlargement of Henry IV, and later by the new and greater fortifications of Louis XIV. The grand boulevard, on the right bank, from the Bastille to the Madeleine, runs along the line of the northern walls of Louis XIV, which were thrown down and demolished by Louis XV. The present walls were the work of Louis Philippe. A project is now in hand to demolish them, at least in part, but up to the present the walls are intact and there is a disposition on the part of Parisians to insist upon maintaining the fortifications, although an interesting project for their demolition has been put forward which would give the city in their place a circle of parks and

ern civic art. Historically and architecturally it ranks with Athens, Rome and Vienna as one of the three most wonderful cities of the world. Since the work of the third Napoleon and his architect-engineer, Baron Haussmann—a work, it is fair to say, which has been and is zealously and intelligently carried forward under the republic—in opening new thorough-

Paris under Henry IV.

extend the avenue des Champs Elysees to the terrace at Saint Germain-en-Laye.

Civic Art and Civic Charm.—Paris was the pioneer in the modern scheme of civil regeneration intelligently conceived and carried out in a large way. Accordingly it is now par excellence the city beautiful, and the leader in the more decoratively æsthetic features of mou-

Paris under Louis XIII.

fares and in the construction of many new and splendid public buildings, in virtue of the essential physical regeneration of the city resulting from this construction and reconstruction which dates from the second empire, Paris has been incontestably the first of cities. Under the operation of the building laws and the regulations as to height, size, general character and style, pursuant to which Paris has been built and rebuilt for the past half century at least, the city may be said to be built to a scale—the form and quality of the construction being prescribed, and each new house as it were commencing as and where the last house left off. Paris is thus made to constitute architecturally a civic entity, an ensemble, “a city with foundations,” and not a heterogeneous and promiscuous collection of houses, with a miscellaneous assortment of taste in their construction. There is for example a uniform sky line as much as a uniform street line, with no architectural monstrosities, and with everything built under a central intelligent supervision, as part of a preconceived plan, which eliminates lawless individualism and the architectural vagaries resulting from personal caprice. Thus everything is made to conform, as part of a substantial uniformity, and to square with prescribed canons of good taste in building. The streets of Paris accordingly display a pleasing elegance which

is not the result of accident, and evince a unity in the scheme of construction, which, without being monotonous, delights the sense of order and proportion by its form and fitness. We find men coming from all parts of the globe, and seeing here something better than mere wealth of luxury and amusement, something more than splendid palaces, sumptuous edifices and a multiplicity of promenades, avenues and boulevards. To all men who reflect Paris has a charm quite independent of its external beauty. Among Americans of our heroic age, Thomas Jefferson, Benjamin Franklin, the Livingstons, Gouverneur Morris and Robert Fulton; and among literary Englishmen, Richardson, John Wilkes, Horace Walpole, Gibbon, Hume and Sterne breathed with delight its intellectual atmosphere, and few men of later days are impervious to the fascination.

Paris at the opening of the reign of Louis XIV.

How to Account for Paris—its Raison d'être.—Paris, like ancient Rome, and perhaps like earlier Babylon and in some degree like later Florence, grew great not primarily by commerce and trade nor by manufacture, but essentially as a city-state, as a capital, as the capital not alone of France but of the modern world. Consequently there is no basis for comparison with Pittsburgh, or Lille, or Manchester as a manufacturing town, or with New York or London (her only rivals in wealth and population) in trade and commerce. Her primacy is in none of these things, although necessarily she is great in trade and considerable in manufacture. It is not easy to formulate and disclose the secret of this obvious pre-eminence; but it is the pre-eminence of a capital pre-eminent. Paris is certainly exceptionally great in few things that makes a market town, while it is superlatively great in everything that makes a capital. Its evolution through the centuries has been along these lines, and its unique posi-

tion among the great cities of the world is now based essentially upon the fact that modern civilized mankind has here its common seat and centre. There is in the Christendom of to-day a gravity of Paris. The whole world tends here; each individual from every country on the globe, going abroad or who has gone abroad these 1,000 years past, came and comes here—merchant, artist, student or merely curious traveler—each comes here necessarily and inevitably, each finds here his heart's desire and contributes each his mite of money and admiration. Thus Paris is the sure goal of every traveler; wherever else he may go or stay, he comes here as to a capital, and stays here as in the capital. In this way alone, as it would seem, can one account for the material as well as the spiritual greatness of Paris, which has no other adequate foundation.

This distinctive fact in the psychology of Paris grows upon one as he comes to know and to love the great city and to feel at home within her walls—a fact, moreover, not likely to be minimized by those Americans who are something more than blind provincials. It is very certainly a fact that cannot be made away with or looked out of countenance by insular, racial or political prejudice, by local conceit or by sheer intellectual inaptitude—a fact, furthermore, that appeals powerfully to the philosophical student of modern history as well as to the enlightened man of the world. Napoleon, saying "I know full well that London is a corner of the world, while Paris is its centre," formulated this idea. There is room for but one such city in such a world as ours at a time, and it takes 1,000 years to build; so that one may say, not merely as a rhetorical flourish, that what Rome was Paris is. She might still maintain this general capital position in the world—as Rome has done in matters of the spirit—although the France of which she is political capital should one day lose her present commanding position in the concert of Europe and sink, like Spain, to a fifth-rate power. Although, according to the common saying, Paris is France, it is something more; a sort of *imperium in imperio*, with a clientèle as wide as the world, and a vogue that extends to the verge of civilization. She has moved the centre of the world's gravity away from the city of the Cæsars and fixed it in the valley of the Seine. Set like a jewel and crowned as a queen, she holds her position sure as the head and front of the modern world, with a distinction and a grace that she never seemed less likely to lose than to-day.

The University.—Alone among the great capitals of the world, Paris is the site of the old university of the nation. The university had its cradle as early as the latter part of the 8th century on the island of the city in the cloisters of the cathedral, between the church and the larger arm of the river on the northerly side. The tradition is that the foundation dates from 780, when Charlemagne called the famous Alcuin to Paris, and established a school for him at Notre Dame. An echo of the tradition—whatever the tradition itself may be worth—has come down all the way from the 8th to the 20th century. Saint Charlemagne is the patron saint of the university, and every year on the 28th of January, which

is his day in the calendar, the schools take holiday. The authentic annals, however, seem to commence with Pierre Abelard about 1107. Under him the institution still in the cloisters of the cathedral began to gain that international prestige which it has never lost. The pathetic romance of Héloïse and Abelard lends a sentimental interest both to the time and to the place. The site of the house where these unhappy lovers lived is marked by a plaque on a wall on the Quai aux Fleurs. Abelard is said to have conferred upon himself the degree of doctor of divinity while he was connected with the university. Henry II of England submitted to the great council of the university his quarrel with Thomas à Becket of Canterbury in the 12th century. In 1200 it received a royal charter

Paris at the close of the reign of Louis XIV.

from Philippe Auguste; in 1208 Innocent III gave it a papal charter; and in the 14th century Charles V conferred upon it the title of "the eldest daughter of the kings." The term "university" as signifying a collection of schools of higher learning originated in Paris. It was first employed in connection with this institution, in the Bull "*Scientiarum fontem*" of Urban IV in 1264, wherein it is designated as the "*Universitas Parisiensis*." The degrees of bachelor and master of arts also originated here. The university remained on the island and under the shadow of the cathedral until the beginning of the 13th century, when it passed over into the rue de la Harpe on the left bank and slowly climbed up the hill of Sainte Geneviève. The first buildings of the faculty of arts were put up in what is now the Latin quarter in the 13th century near the church of Saint Julien le Pauvre in the old rue du Fouarre. The university grew and prospered throughout the latter half of the Middle Ages under the patronage of the Church and of the kings. The Faculty

of Law and the School of Medicine were both founded in the 12th century, the law school dating from 1160. From the beginning of the 13th century to the end of the 16th the Sorbonne was a sort of international theological parliament which the nations and kings of Europe consulted on great political and religious questions (as, for example, Henry VIII, of England, on the annulling of his marriage with Catherine of Aragon), and which assumed the function of pronouncing upon the orthodoxy of new books, condemning to destruction by fire such as were not conformed to its ideas. As early as the 16th century the university had from 12,000 to 15,000 students, drawn from every quarter of the earth. They all learned to speak an extraordinary mixture of French and Latin, in which the work of the schools was then carried on, and it was not until the end of the reign of Henry IV that this jargon was displaced by idiomatic French. Because Latin was the language of the university, the region of the schools was called the *Pays Latin*, or, in our modern phrase, the Latin quarter. Then the language was indeed Latin of a sort; now students from every land and all tongues, except Latin, stream through the streets of the quarter with the polyglot Bohemianism of comradeship which has become such a Parisian characteristic. During the Middle Ages there were at the university separate colleges for each of the four nations, France, Picardy, England and Normandy, with much rivalry between them. After the re-entry of Charles VII to Paris in 1437, the college of England was changed to that of Germany. Seals of these collegiate "nations" are preserved in the British Museum. The university was governed by a rector for many centuries, who during the Middle Ages was the supreme power in all the territory of "*l'Université*" both in civil and criminal affairs affecting the students. It was the privilege of the students to be condemned and hanged only by the court of the rector. It is an interesting fact that the messengers of the students in the Middle Ages, who carried letters and packages to and fro for them from their homes, were the forerunners of the post office system of Louis XI, which was the first attempt at a regular postal service anywhere. The annals of this great school reaching far back into the Dark Ages constitute one of the most fascinating episodes in history. The University of Paris has, ever since about the end of the 12th century, been the intellectual centre of Europe, and the chief seat of light and learning in the world. All the other and later universities, like Oxford and Heidelberg, have been modeled after it. No other university can compare to it in the number of distinguished men it has numbered among its students. Thus, in the long roster are such names as Dante—second poet of mankind—Pierre Abelard, François Villon, Pierre de Ronsard, Tasso, Rabelais, Clément Marot, John Calvin, Ignatius Loyola, Innocent III, Francis Xavier, Erasmus, Melanchthon, Pascal, Rollin, Saint-Pierre, Descartes, Voltaire, Rousseau, Robespierre, Diderot, Condorcet, Molière, Racine, La Fontaine, Boileau, Lamartine, Sainte-Beuve, Victor-Hugo, Comte, Taine, Renan and all the moderns. At present there are ordinarily in Paris from 15,000 to 18,000 students in attendance on the courses of the

university (among them about 5,000 in the law school), together with several thousand more in the various technical, art and industrial schools which work independently of the university; for example, the Collège de France, the Beaux-Arts, the Polytechnic School, École des Ponts et Chaussées, the School of Mines, the Normal School, the Conservatory of Music, Arts et Métiers, Hautes Etudes, the École des Chartes, the School of Living Oriental Languages, the special schools of art and architecture, etc. Thus there are always in Paris an average of not less than 25,000 students of one sort and another—not including the students in the various lycées and colleges—constituting in the whole a very much greater number from the four quarters of the earth than are to be found elsewhere in any one place in the world; and the university of to-day, as much as ever, is in numbers and in world-wide influence the first of schools of learning anywhere. The 27 libraries of the university contain in the aggregate, according to a recent enumeration, 1,188,000 volumes. The following statement of enrolment in 1914 and 1915 is furnished by the information department of the university:

On 15 Jan. 1914, there were enrolled 17,308 students, of whom 15,111 were males and 2,197 females; of the former 12,946 were of French and 2,165 of foreign citizenship, and of the latter 1,120 were of French and 1,077 of foreign citizenship. This total enrolment of 17,308 was distributed among the various faculties as follows: Law, 7,569; medicine, 4,397; sciences, 1,718; letters, 3,018; pharmacy, 606. On 31 July 1915 (after a year of war) the university had a total enrolment of 4,257, of whom 3,323 were males and 934 females; of the former 2,385 were of French and 938 of foreign citizenship, and of the latter 663 were of French and 271 of foreign citizenship. The enrolment in the several faculties was as follows: Law, 1,165; medicine, 1,186; sciences, 751; letters, 959, and pharmacy, 196.

Public Instruction—the Free Schools.—

The principle of free public instruction in France dates from the Revolution, but the public school system of Paris in its present form is substantially the work of the Third Republic. It commences with the maternal schools (*écoles maternelles*) directed by women, which receive children of both sexes from two to six years of age, and give them care and elementary instruction in reading, writing and ciphering. These schools are scattered throughout the city, but of course are especially designed for the poorer quarters where the many young mothers who are employed in shops and factories can place their infant children during working hours. Next come the primary schools, separate for boys and girls, which receive and instruct children from 6 to 13 years of age. Pupils go from these schools to the superior primary schools, and thence for secondary classical courses to the lycées and colleges, which confer the degrees of bachelor in letters and bachelor in science. A French boy usually takes his bachelor's degree when he is about 16 or 17 years of age. It is thus not the equivalent of the A.B. or B.S. in America, representing here on the contrary something like a certificate of graduation from an average American city high

school. There are 10 superior primary schools, six lycées supported by the city, and two by the state, and three colleges; these lead to the university and the professional and technical schools. There is also a system of free public night schools for adults, both men and women. There are about 125 of these schools with some 12,000 pupils.

There are in connection with the various public schools about 400 libraries containing useful and instructive books to be loaned to the pupils. In addition necessary books and stationery are furnished free to all the pupils in the primary and superior primary schools. The city also furnishes to all the day scholars a déjeuner, that is, the meal at the noon hour, consisting of hot soup, meat and vegetables, prepared and served in the cuisine of the school. The children are supposed to bring in their little baskets a bit of bread and a bottle of wine, but when they do not, bread is also furnished. Some parents pay a small fee when they are able, for this luncheon, but the poor pay nothing, and by a system of copper checks, which are given out to all the pupils every day and surrendered at each meal, it is impossible to know who pays and who does not. Shoes and clothing are also provided for children whose parents are unable to furnish them. The keynote of Paris public school administration is the absolute equality of the scholars while they are in school. The tendency to clothe school children in dark blue or black blouses makes this fairly easy. Elementary education is obligatory as well as free. Mixed schools are not tolerated in Paris. During the summer vacation the city provides excursions—from a day or two to a month in length—for the children of the poor, to the seaside or to the country, sometimes to Switzerland. Each child is required to keep a diary of his excursion whether it is long or short, which is subsequently treated as an exercise in composition. The system of primary instruction is, upon the whole, an admirable one. It cares for and educates all the children of the city.

Churches.—Among the monumental buildings that adorn the capital the cathedral of Notre-Dame holds the first place. Its foundations were laid upon the ruins of a temple of Jove, first about 375 A.D., and rebuilt again and again; the present edifice upon the original site having been begun in 1163. The choir was finished in 1195, the façade in 1218 and the towers in 1225. It was the first conspicuous embodiment of the Gothic ideal in church architecture—the mother church from which has come down in ordinary generation that prolific family of Gothic churches throughout the world, which stands sentinel about the Ile de France in a widening circle from Rheims and Amiens, from Rouen, Beauvais and Chartres to Cologne and Milan, to York, Canterbury and Lincoln and to the ends of the earth.

Notre-Dame de Paris is accordingly not only one of the oldest, largest and most interesting churches in the world, but it is architecturally one of the most impressive buildings ever erected. Philip Gilbert Hamerton, than whom there is scarcely a more competent contemporary critic, says that if we leave out of view one or two Greek temples nothing ever constructed by the hand of man has been so uni-

versally admired as the façade of Notre-Dame—and that is also almost true perhaps of the whole structure. There is about it an indescribable charm. Neither Saint Peter's nor Milan nor Saint Mark's so nearly satisfies the highest religious and æsthetic emotions.

Victor Hugo well characterized it as a "vast symphony in stone." And Hilaire Belloc, to whom the great church so poetically appeals, says:—"To a man who knows and loves the city, there soon comes a desire to constantly communicate with the memories of the cathedral. And this desire, if he is wise, grows into a habit of coming close against the towers at evening, or of waiting under the great height of the nave for the voices of the middle age." Although it is more than 700 years old it is in an excellent, almost perfect state of preservation, the conscientious and intelligent restoration of the entire structure by Viollet-le-Duc at the middle of the last century leaving little to be desired. Its towers were the most conspicuous monuments of mediæval Paris, and from their base all distances from Paris are calculated. It is interesting to note here that all the churches and historical monuments of France are catalogued by the Ministère des Beaux-Arts and that no restoration or so-called embellishments can be made without passing through the "service d'architecture des Monuments Historiques" so ably directed by M. Paul Léon.

Next after Notre-Dame the most interesting church in Paris from an architectural point of view is the Sainte Chapelle at the Palais de Justice. It is said to be the most perfect specimen of pure Gothic architecture in existence. It was built by Louis IX in 1245. Here for many generations until recently was celebrated every year at the opening of the courts in October the "red mass," attended by the bar and the judges in their scarlet robes. This mass is now said at Saint Germain l'Auxerrois. During its long history this beautiful chapel royal has been the site of many coronations and other kingly ceremonies. Saint Julien le Pauvre, which in its origin goes back to the first centuries of the Christian era, is a little church in the Latin quarter built in the 11th century. It stands just out of the rue Saint Jacques in the rue Galande. It is interesting not only as a beautiful specimen of early Gothic, but also because it was for many years a sort of chapel to the university, where the council was convoked, and where the rector had his official seat. Saint Germain des Prés, in the boulevard Saint Germain, founded by Childebert in 543, with its barbaric tower of the 9th century, is the most venerable monument on the left bank. Saint Eustache, at the markets, begun in 1532, a church of great size and impressiveness; Saint Sulpice, near the Luxembourg, with its great organ and fine music; Saint Roch, in the rue Saint Honoré from the steps of which Bonaparte, then a young officer of artillery, trained his cannon upon the mob at the commencement of the Revolution, and from which he may accordingly be said to have set out on his extraordinary career; Saint Augustin in the boulevard Malesherbes, and Saint Clotilde near the Palais Bourbon, two modern churches of great size and beauty; Saint Thomas d'Aquin, the most fashionable church of the faubourg Saint Germain; Saint Etienne du Mont, under the

shadow of the Pantheon, with its beautiful jubé, or rood-loft, of exquisite workmanship, and the two graceful staircases ascending to it, the jubé dating from 1609; the Madeleine, in the grand boulevard; Saint Vincent-de-Paul, with its splendid approach from the rue LaFayette, and Saint Germain l'Auxerrois at the Louvre, are among the most notable of the churches. The new and splendid church of the Sacré Cœur on Montmartre, commenced after the war of 1871, and conceived in expiation of the murder of the archbishop of Paris by the Commune, is the most considerable religious edifice which has been built in modern times. It has already cost upward of \$8,000,000, and is still far from completion. Paris is divided into 70 parishes, and there are in all about 140 places of worship, of which 86 are Catholic. Almost every sect in the world has a church in Paris, and religious services are conducted in all the principal languages of civilized and semi-civilized mankind. The churches of Paris are among the most interesting features of the city, entirely apart from any religious consideration; so much of the stirring history of the town is written in the stones of her great churches.

Galleries of Art and Museums.—The Louvre with its unrivaled collection of *objets d'art* is the chief art gallery of Paris. The Louvre itself was a royal castle from the days of Philippe Auguste until Louis XIV built the palace at Versailles. The existing structure which superseded the work of Philippe Auguste was begun by Francis I in 1541, and was added to and extended by his successors down to and including the third Napoleon. As finally completed it constitutes the grandest urban palace in the world, and one of the most extensive and historically interesting buildings on the earth. Since 1793 the greater part of the interior has been occupied by the famous museum and art galleries of the Louvre, although the wing on the rue de Rivoli is occupied by the Ministry of Finance. It may be said to be the most important public building in Paris. It has an unrivaled situation on the Seine and on the rue de Rivoli, facing the gardens of the Tuileries and the Place de la Concorde. It covers an area of more than 48 acres, and only the papal palace of the Vatican can be compared to it for size and magnificence. It is interesting to note by way of comparison that the public buildings in Philadelphia cover $4\frac{1}{2}$ acres, the Louvre being thus in area $10\frac{2}{3}$ times as large. The galleries contain a vast collection of paintings, sculpture, objects of art and antiquities to which only the collections of the Pitti-Uffizi Gallery at Florence and of the Vatican at Rome can fairly be compared. They are free, and open to the public at fixed hours daily. The next gallery in importance and interest is that of the Luxembourg, in the gardens of the Luxembourg adjoining the palace. It is a museum of no great size of living artists, opened in 1886. There is a plan now in hand to rebuild and enlarge it by annexing the adjacent Seminary of Saint Sulpice. Among the great number of other collections may be mentioned the Musée Cluny, in the boulevard Saint Germain, dating from 1840, possessing not only the interesting Roman ruins of the ancient Palais de Thermes, but also a valuable collection of mediæval furniture and objects of art from the Middle Ages; the Musée Carnavalet—the museum of the city

of Paris—containing an invaluable collection of objects connected with and illustrating the history of the city in all its centuries of existence, located in the hotel of Madame de Sévigné, in the rue de Sévigné, in the Marais, once the centre of fashionable life, but now rather a neglected quarter; the Musée of Artillery at the Hotel des Invalides, containing a very large collection of arms, ancient, mediæval and modern, of all sorts, cleverly displayed in a chronological order; also Napoleon's camp bed, some of his uniforms, the famous gray overcoat and many of his camp furnishings; the Musée of the Trocadéro, which contains a collection of sculpture illustrating various phases of ancient and mediæval architecture, being especially rich in early French churches and royal tombs, together with an interesting ethnographic exhibition; the Musée Guimet; the Musée Galliera, in a new and palatial structure of exceptional artistic beauty, in the rue Galliera, not far from the Trocadéro, etc.; the long list including more than 50 separate public collections of varied and general interest. No city in the world contains a greater number of valuable private collections, many of which are accessible to students and sightseers, on proper introduction.

Libraries, Books and Publications.—No city was ever so rich in books and libraries and literary treasure as Paris. The Bibliothèque Nationale has always been unrivaled. It has been known in its long history successively as La Bibliothèque du Roi, Royale, Nationale, Impériale, and now Nationale again. It was founded in the 14th century by John II, and then consisted of but 8 or 10 volumes; it was housed at first in the Palais de la Cité. Charles V is sometimes called its founder because he removed it to the Louvre and increased it to 910 volumes during his reign. Some books of Charlemagne's are said to be included in this first collection. Francis I transferred it to Fontainebleau, but it was brought back to Paris by Henry IV. Subsequently it was stored in various places in the city, but was finally located in the Palais Mazarin, in the rue Richelieu, now more than 200 years ago, where it has since remained. Although it is a building of vast size, it has recently been greatly enlarged by a splendid addition in the rue Vivienne. Under Francis I it contained 1,890 volumes; 16,746 under Louis XIII; 50,542 under Louis XIV; and about 100,000 at the time of the destruction of the religious houses during the Revolution, at which time their libraries were incorporated with it. It now contains 4,050,000 printed books, 100,000 manuscripts, 2,500,000 plates, engravings, stamps and maps, and 120,000 medals and inscriptions. It is a public library, free for study, reading and reference, with no vexatious restrictions, at all times except holidays. Other noted libraries are the Bibliothèque Sainte Geneviève, with 400,000 volumes and 3,500 manuscripts; the Bibliothèque de l'Arsenal (which, after the Bibliothèque Nationale, is the finest in Paris), with 620,657 volumes, 10,000 manuscripts, 2,500 cases containing papers and documents from the Bastille, and 100,000 engravings; the Bibliothèque Mazarine, with 250,000 volumes and 5,000 manuscripts; and the Bibliothèque de la Ville, with 400,000 volumes, 25,000 manuscripts and 75,000 engrav-

ings and charts. There are also many technical libraries at the various schools and colleges of the university and elsewhere for the use of students and investigators. In addition to the libraries of the university (1,188,000 volumes), to which reference has already been made, mention should be made of those of the Senate, of the Chamber of Deputies (250,000 volumes), of the Council of State at the Palais Royal, of the Institute, of the School des Beaux-Arts, of the School of Mines, of the Hotel des Invalides, of the Chamber of Commerce, of the several ministries (War, Marine, Colonies, Justice, the latter containing 40,000 volumes), of the Conservatory of Music, of the Opera, of the Theatre Français, etc. The Archives Nationales must also be mentioned in any enumeration of Parisian libraries. It occupies the beautiful hotel Soubise, in the Marais, and, as its name indicates, contains a collection of national archives dating from the Merovingian kings, an immense number of charters, maps, letters, documents of all sorts, of the kings, of the Parliaments, of the empire, and of the ancient Parisian jurisdictions like the Chatelet, the Chamber des Comptes, etc. From this enumeration of the literary treasure of Paris, it is clear that nowhere else are there such facilities for study and historical research as here. The city of Paris, moreover, maintains 79 free public libraries—two or more in each of the 20 arrondissements—for lending books to laboring people and students, at most of which reading-rooms, suitably warmed and lighted, are opened in the evenings for the use of persons who are engaged during the day. According to a recent enumeration made for the Library of Congress in Washington there are in the 17 principal public libraries of Paris a total of 8,750,657 volumes, as against 5,740,406 in the libraries in London and 3,430,094 in Berlin, or about as many books in Paris as in London and Berlin combined.

There are 146 daily newspapers in Paris (many of them in foreign languages), which is more than the total number published in New York, London and Berlin combined. The leading daily papers are *Le Figaro*, a temperately ministerial organ and the organ of society, a paper that had a certain notoriety from espousing the cause of Dreyfus; *Le Gaulois*, the organ of the Church and the old aristocracy, conducted by Arthur Meyer, a clever Jew who has been Christianized and has married into the family de Turenne; *Le Matin*, an enterprising, newsy paper; *Le Journal*, a paper in favor with the mercantile and commercial classes; *L'Echo de Paris* and *L'Éclair*, both journals of large circulation and influence; *l'Intransigeant*, founded by Henri Rochefort, who was long one of the most accomplished men on the Paris press and whose paper is always implacably hostile to the government; *Le Journal des Débates*, a conservative organ of high character but of no very large circulation; *L'Autorité*, the Bonapartist organ of Paul de Cassagnac, the famous duelist, whose skill in journalism was quite comparable to that of Henri Rochefort; *l'Humanité*, founded by Jean Jaurès, as the organ of the advanced Socialists. It was at its foundation supported actively by Anatole France and other literary men of Socialistic tendencies; *La Croix*, the Church organ par excellence, with an enor-

mous circulation in Paris and the provinces; *Le Temps*, the leading evening paper, conservative and serious, and read by the best people; *La Patrie*, a sensational evening organ, with an immense following; *Le Petit Journal* and *Le Petit Parisien*, the two great organs of the masses, each with a circulation exceeding 1,000,000 copies daily; *La Libre Parole*, edited with ability by the late Edouard Drumont, a violently anti-Semitic organ; *La Gazette de France*, an exceedingly conservative sheet, which dates back to 1631, making it, as it claims, the oldest newspaper in the world in any language. According to *L'Annuaire de la Presse française et du Monde politique*, there were a few years ago in Paris 3,442 periodical publications (of which over 1,400 were newspapers), a number at least three times as great as that of any other city. Furthermore, the annual output of books from the Paris press is said to exceed the total output in the English language from all sources. Nothing suggests better than the foregoing statements the intellectual activity of the French capital.

Financial Paris.—Chief among the financial institutions of Paris are the Bank of France and the four great private banks, the Crédit Lyonnais, the Comptoir National d'Escompte, the Société Générale and the Crédit Industriel et Commercial. The banking business of the city is largely in the hands of these five institutions. The Crédit Lyonnais has a sumptuous banking house in the boulevard des Italiens, a capital of 250,000,000 francs, a surplus of 100,000,000 francs, and real estate of the value of 37,000,000 francs, with deposits, 31 Dec. 1904, 1,656,000,000 francs. It has 65 branches in Paris and the suburbs, 140 branches throughout France and 17 branches in foreign countries, including two in London. It has behind it the financial power and prestige of the Rothschilds, and its influence is felt in financial circles everywhere. It is unquestionably the largest and most powerful private bank in the world. The Comptoir National d'Escompte has a capital of 200,000,000 francs, 61 branches in Paris and the suburbs, 98 throughout France and 19 abroad. The Société Générale has a capital of 500,000,000 francs, 102 branches in Paris and the suburbs, 306 throughout France and one in London. The Crédit Industriel et Commercial has a capital of 126,000,000 francs and 52 branches in Paris and the suburbs. These four institutions, with aggregate capital exceeding \$200,000,000, thus furnish Paris about 280 banks, with 550 branches in France and 40 abroad. There are, of course, many other smaller banking institutions in Paris. The Bank of France, like the Bank of England, is a private joint-stock bank, and not an institution of the state. It has, however, the sole right to issue bank-notes which are guaranteed by the state, and is thus peculiarly subject to governmental control. Its ordinary banking business (aside from the business it transacts for and with the government) is on the most extensive scale. The idea of a Bank of France originated with Francis I, who established, in 1543, at Lyons, the first national bank. But the bank in its present form was organized in February 1803 by the First Consul, with a capital of 30,000,000 francs, which has since been increased from time to time, until it is now 182,500,000 francs. Napoleon's name

heads the list of the first subscribers to the capital stock of the bank. The limit of note issue fixed by the government is 4,000,000,000 francs, or about \$800,000,000. This limit is, however, generally exceeded, and, by a late report of the bank, it appears that there were then outstanding notes to the amount of 4,510,000,000 francs. The gold and silver treasure of the bank, on the same day, was 4,750,000,000 francs, which amounts to the enormous sum of \$950,000,000. The bank has 445 branches throughout France. The chief office is in the rue de la Vrillière, in the old hotel de la Vrillière, to which extensive additions have been made from time to time. It contains a handsome apartment of the 18th century, called the Gallere Dorée, to which visitors are admitted. The cellars and vaults of the bank are of elaborate construction, and can be flooded with water at a moment's notice on an alarm of attempted burglary. The remarkable financial strength of Paris nevertheless contained within itself an element of weakness for the country, in that a large proportion of French savings were systematically exported abroad to needy foreign states, while domestic development was neglected. English treasury bills, exchequer bonds, bankers' acceptances and other sorts of English short-dated securities quickly find their way to Paris, and a volume of the best short-time New York paper is also always found in the thick portfolios of the Paris bankers. For many years previous to the war the rate of the Bank of France had fluctuated very slightly, being generally maintained at 3 per cent. During an economic crisis it was raised to 3½ per cent on 29 Jan. 1914; to 4½ on 30 July 1914; to 6 per cent on 1 Aug. 1914, and reduced again to 5 per cent 19 days later, at which figure it still remained in May 1919. Before the war Paris was the ready money centre of the world, for nowhere was there a larger stock of available funds than in France. "We are perhaps the biggest money-lenders in the world," said a French finance minister in 1911, but he deplored the non-existence of "organisms the sole object of which should be to assist small business men and manufacturers." Paris was the only financial centre in the world through which, for example, such transactions as the cash payment of \$40,000,000 in gold coin for the Panama Canal, or even the payment of the \$20,000,000 in gold which we made to Spain for the Philippine Islands, could have been arranged. Both these payments were made over the counters of the Bank of France. The war of course modified essentially the ordinary operations of the bank. With the *com forcé* it issued bank notes without reference to the legal limit and is financing the government in the larger way. The gold reserve has been very largely increased.

La Bourse.—The Bourse was founded in 1734, but the Change de Paris, out of which the Bourse grew, has a history running back to the first years of the 14th century (1304 A.D.). Stockholders, or *agents de change*, operated for many years in the old rue Quincampoix in the Marais, and later in the Place Vendôme and in the hotel de Soissons, on the site of which now stands the Bourse de Commerce, which is the Parisian Produce Exchange. The present Bourse or stock exchange building was

begun in 1808, when Napoleon laid the cornerstone. It was completed in 1826 and opened by Charles X. The Palais de la Bourse, as it is called, is a handsome building, in the Græco-Roman style, surrounded by a series of 82 Corinthian columns, 33 feet high and 3½ feet in diameter. The setting and the architectural effect are fine, suggesting the temple of Vespasian in the Forum at Rome. The length (exterior) is 225 feet; the width, including the new wings, 215 feet; and the height 100 feet. The hall is 105 by 57 feet, with wings on either side in the recent addition, about 40 by 60 feet each in size. It is a shapely and commodious room, and the decorations are artistic. The Bourse stands in a block by itself, facing the fine Place de la Bourse, which is about midway between the boulevard Montmartre and the Bank of France. While there are 1,100 seats in the New York Stock Exchange, and near 5,000 (4,085 in 1919) jobbers and brokers on the London Stock Exchange, there are only 70 memberships in the Bourse. They are, therefore, more valuable than memberships in any other exchange in the world, being worth at present from \$350,000 to \$500,000. The position of *agent de change* is a quasi-governmental one, the appointment to the office being by the Minister of Finance, and the operations of the Bourse being, at least indirectly, under the control of the state. The membership, or, as we say, the seat, is a life estate, which can be disposed of by will to a son or nephew only, and that subject to governmental approval. The hours are from 12:30 to 3 o'clock each business day. The *agents de change* have an exclusive privilege of negotiating transfers of public funds and the sole right of buying and selling securities of all kinds on the Exchange. The annual amount of business transacted in ordinary times is estimated at 100 milliards of francs, or \$20,000,000,000. The foreign list, which is dictated by the government, consists of the obligations of all the other nations of Europe except Germany (Russian, Spanish and Turkish securities were generally favorites), the bonds of the more solvent and responsible countries of South America, and of Egypt and Morocco. The bonds and stocks of some foreign railways are also listed, as well as those of many foreign industrial concerns, like the Rio Tinto mines in Spain, the Suez Canal, etc. Few American securities have yet been listed, but just before the war efforts were successfully made to increase this list. German securities are never dealt in, and English investments are not favorites. There is, however, some trading in English consols. The obligations of the Crédit Foncier are also largely dealt in. This is a financial institution of enormous resources—quasi-governmental in character—organized in 1852, for the purpose of lending money, primarily on the security of real estate. It is said to be one of the fundamental institutions of public credit in France, and is of great service to the communes in advancing them money for public works. Its securities are a favorite investment. *La Cou-lisse*, a sort of loose association of unlicensed *agents*, whose transactions are purely speculative and carried on during business hours, corresponds in a way to the "Curh" of the New York Stock Exchange. *La Petite Bourse*, a somewhat similar organization, carries on speculative transactions in the daytime, before and

after the hours of the Bourse. *La Bourse du Soir* is the name for a group or groups of speculators who meet and trade or speculate in the evening, suggesting roughly the famous evening meetings of stock-brokers at the old Windsor Hotel in New York.

The American Chamber of Commerce in Paris.—This institution was founded in 1894, mainly through the efforts and initiative of Dr. Stephen H. Tyng, then the Paris representative of the Equitable Life Assurance Society. It has its offices at 3 Rue Scribe, and represents in its corporate capacity the commercial interests of the United States in France. In 1919 it reported 700 active members (of which 284 were resident) and 72 honorary members, from among the most substantial class of American bankers, professional people, manufacturers and merchants resident in Paris or interested in French business. The American Ambassador for the time being to the French Republic, and the consul-general of the United States in Paris, together with the presidents of the chambers of commerce in most of the chief cities of the United States, are honorary members. A library and reading-room is maintained, and the work of the chamber is efficiently carried on. It is quite the first such institution in Europe and performs a very useful function both commercially and socially.

The Hotel de Ville.—In any history of Paris the Hotel de Ville and the events, political and revolutionary, which have occurred there must have a prominent place. Its history is bound up inseparably with what is best and most inspiring in the annals of the capital. For almost 550 years it has been the town-hall of Paris, the centre of its civic life, and it has at every stage played a conspicuous part in the different revolutions as the rallying place of the republican or democratic party. Indeed, it may not untruly be said that universal suffrage and democracy in the modern sense were born there. It was in 1357 that Etienne Marcel—first of democrats, and the most famous of the ancient *Prévôts des Marchands*—purchased for the city of Paris "the House of Pillars" on the Place de Grève and established there the municipal headquarters, which had theretofore been at the ParLOUR of the Bourgeois, on the other side of the river. This latter ancient municipal structure—in reality the first Hotel de Ville—dated from the 9th century, and was built against the city wall at a place near the rue Soufflot. The House of Pillars continued to be the seat of the municipality until it was demolished by Francis I in 1532, to make room for the new Hotel de Ville, begun by him in that year and completed in the reign of Henry IV. It contained the residence and offices of the chief municipal functionary of the city, who was called the *Prévôt des Marchands* down to the Revolution, and thereafter *Préfet de la Seine*. This building was enlarged and reconstructed from time to time, and was finally destroyed in May 1871 by the Commune. The present building, which may be described as an enlarged reproduction of the original, was undertaken by the republic shortly after the war of 1871. It is, architecturally, one of the finest buildings in Paris, and one of the most beautiful municipal buildings in the world. It is a rectangular structure in the style of the Renaissance, with the most elaborate ornamentation, exterior and

interior. After the Grand Opera, it is the most sumptuous public edifice in Paris. The Place de l'Hotel de Ville, formerly the Place de Grève (that is, river bank), was anciently the place of execution. In 1572, after the massacre of Saint Bartholomew, Catherine de Médicis condemned the Huguenot leaders to perish on the gallows here, and from that time to the close of the Revolution it witnessed a long series of political executions. The colors of the city of Paris—red, white and blue—have for centuries been the recognized colors of democracy. They became in 1775 the colors of the American republicans, and in 1789 of French republicans. So that the American flag and the French tri-color alike hark back to the banners that Etienne Marcel flung out, as the badge of his mediæval republicanism, from the House of Pillars on the Place de Grève, at the middle of the 14th century. From that day to this the spirit of Paris has been democratic; it has always been more or less at swords' points with the crown, the head and front of the third estate.

The Senate and Chamber of Deputies.—

Next after the Louvre, the Palais du Luxembourg, which is the seat of the Senate, is perhaps the most notable palace in the city. It was erected in 1615–20 for Marie de Médicis, the widow of Henry IV, and was modeled in general after the Pitti Palace in Florence. Its name comes from the fact that it is built upon the site of the ancient hotel of the dukes of Luxembourg. It has at times been used as a prison, especially during the Revolution and shortly after. The Musée du Luxembourg—a gallery of modern art—and the fine gardens of the Luxembourg adjoin it. The Senate chamber is a handsome room, richly decorated, in the part of the building next to the gardens. It is in form a double hemicycle, the larger with 300 seats and desks for the senators, the smaller for the president of the Senate. The light comes from the dome, and the general effect is dignified and imposing. The Palais Bourbon, in which the Chamber of Deputies has its seat, is situated on the left bank of the Seine, facing across the river to the Place de la Concorde. It was built by the Prince de Condé in 1722 at a cost exceeding 20,000,000 francs. In 1790 it was confiscated, and became national property. Both the Senate and the Chamber of Deputies (the procedure in each being essentially the same) are especially interesting to American visitors, not only as the legislative assemblies of the other great republic of the world, but as exhibiting in their procedure several striking contrasts to our own Senate and House of Representatives. The most notable, perhaps, is that, when the members speak, they address their fellow members (and not the presiding officer) from the tribune, a raised platform or pulpit in front of and a little below the desk of the president—which seems to have some advantage. They vote by blue and white cards or tickets deposited in urns, which are carried about, when the vote is taken, by the huissiers, the white ballot being for and the blue against the measure under consideration. Another difference is that no member is entitled to speak on any question unless he has given notice in advance by inscribing his name on the list of speakers. The presiding officers wear full evening dress. They

call to order by ringing a bell, and the close of the session is announced by the president's putting on his silk hat.

The Palais de Justice and the Courts.—Few buildings in Paris are more interesting than the ancient *Palais de la Cité*. Situated near the western end of the island of the city, it was a royal residence continuously from the time of the Roman occupation to the latter part of the 14th century, since which time it has been exclusively devoted to the use of the courts. It was the seat of government under the Romans almost or quite from the commencement of their domination. And thereafter under the successive dynasties that lived and ruled in Paris, for the thousand years from the Roman evacuation to the end of the Hundred Years' War, it was continuously the seat of the king's courts and of the Parliament of Paris, which, in their varying forms, were through the ages the supreme court. Abandoned as a royal residence, and later presented to the Parliament by Charles VII in 1431, it became the Palais de Justice, thus perpetuating its judicial character. It has therefore been the seat of justice in Paris in one form or another from the time of Christ. Hilaire Belloc speaks of the "square mass of the Palais, whence, uninterruptedly, for 1,800 years the government has held its courts and its share in the administration of the town." It has of course been built and rebuilt again and again. The present building dates from the reconstruction of Robert the Pious in the 11th century. Louis IX in the 13th century and Philippe le Bel at the commencement of the 14th century made considerable additions to it. The Sainte Chapelle was the work of the former, and the tower at the northeast corner the work of the latter. The great tower clock dates from 1370, having been, however, reconstructed in 1685 and again in 1852. It is the oldest public clock in France. One of the most interesting features of the present building after the Sainte Chapelle is the *Salle des Pas Perdus*, an immense hall, consisting of two vaulted galleries 240 feet long, 90 feet wide and 33 feet in height, which serves as a sort of vestibule to most of the civil courts of first instance. It is the place where the *avocats* congregate when not engaged in the trial of their causes, and where they meet their clients. Many historical reminiscences attach to it. It dates from Louis IX, and was long known as the Grande Salle. Booksellers anciently had stalls there, and the clergy were for a long time permitted to perform there moral plays and farces. Visitors are shown the kitchens of Saint Louis, in the oldest existing part of the building, next to the river. Near by and in the same part of the palais is the Conciergerie, a prison famous in French annals, where, for example, are to be seen the chamber in which Marie Antoinette was imprisoned and the cell occupied by Robespierre. Among the numerous court rooms the most notable are the chambers of the Court of Cassation and of the Court of Appeal, both large and sumptuous rooms, with superb decorations. The great hall on the western side next to the Place Dauphine is called the Vestibule de Harlay. It contains statues of the four French monarchs most conspicuous as legislators—Charlemagne, Philippe Auguste, Saint Louis and Napoleon—and rivals the *Salle des Pas*

Perdus in size. Opposite the Palais de Justice, across the boulevard du Palais, is the Tribunal de Commerce, dating from 1866. It has a conspicuous dome 135 feet in height. Most of the courts of general jurisdiction in Paris sit in one or other of these two buildings.

At the head of the judicial system of Paris is the Minister of Justice. He appropriately conserves the ancient title of *Garde des Sceaux*. The Ministry of Justice is in the Place Vendôme. The *Conseil d'Etat*, with 45 members, which in some of its functions is a tribunal, and the *Cour des Comptes*, with 84 members, are at the Palais Royal; but all the other general courts are on the island, at the Palais de Justice or the Tribunal de Commerce. First of the courts is the *Cour de Cassation*, with 45 judges, divided into three chambers. Next comes the *Cour d'Appel*, with 62 judges, divided into nine chambers. Then there is the tribunal of first instance, with 70 judges, divided into 12 chambers. These are the three superior tribunals of both civil and criminal jurisdiction. The *Tribunal de Simple Police*, a general court for petty offenses, sits also at the Palais de Justice; it is held by the *Juges de Paix*, sitting in rotation for short terms. The *Tribunal de Commerce*, a commercial court, with 21 judges, has its seat at the Tribunal de Commerce. There is also in each of the 20 arrondissements a civil court (*Justice de Paix*) of inferior jurisdiction, and in each of the 80 *quartiers* a criminal court (*Commissariat de Police*) of limited jurisdiction. Such is a general outline of the judicial system under which Paris is governed. The jurisdiction of each of these courts is roughly suggested by their names. The tribunal of first instance is the ordinary court of general jurisdiction, from which there is an appeal to the *Cour d'Appel*, and thence in certain cases to the *Cour de Cassation*. Commercial cases, however, between merchants and traders are heard by the *Tribunal de Commerce*, which has exclusive jurisdiction in that class of cases. The procedure in all the trial courts is characterized by directness and simplicity. There are no juries in civil cases, and in criminal cases a majority verdict of the jury suffices.

The Observatory and the Mint.—The Observatory has a history going back to 1371. The work was at first carried on in a building which stood on a site northwest of the hotel de Cluny, and which would now be in the middle of the boulevard Saint Germain. Charles V provided the necessary instruments and charts and endowed two scholarships there for the study of astronomical science, the holders of which were called "King's Scholars," it being expressly provided that they were to study only such works as were not forbidden by the Sorbonne. The present Observatory, however, was founded by Louis XIV in 1672. It is an institution of great reputation, and is in telegraphic communication with the most important of the other observatories of the world. It is situated at the end of the avenue de l'Observatoire, south of the Luxembourg. The meridian of Paris is traced through the large hall on the second floor, and the latitude of the south façade is held to be that of Paris. The intersecting point of these two lines is the base from which all geographical and astronomical calculations are made. The meridian was first accurately calculated in the reign of Louis XV, although it had been fixed

at the Observatory in the preceding reign. The Academy of Sciences has traced it in various other parts of Paris; for example, through the church of Saint Sulpice, through the gardens of the Palais Royal and across the top of Montmartre, at each of which places it is marked. At the Palais Royal a little cannon is set in the axis of the meridian, so that the sun by an ingenious contrivance can fire it off every day exactly at noon.

The Mint (*Hotel des Monnaies*) is a large and handsome building on the Quai de Conti east of the Institute, erected in 1771-75. The façade is 400 feet long. The work shops where money is coined are well worth a visit. Aside from the French coinage, which in amount is the largest in the world, these ateliers coin much money for other countries, and also many medals of all sorts. The processes are freely shown and explained to visitors. The machines for the coinage of silver are especially interesting, 60 pieces of money being struck by each of them per minute, with a daily maximum capacity of 2,000,000 francs in value. The assaying and stamping of the gold and silverware of the jewelers is also done here. There is a museum (*Musée Monétaire*) in connection with the Mint, which contains a very complete collection of French coins, arranged chronologically, from the earliest times to the present day; also many foreign coins, among them a good collection of our United States coins, and, by way of a curiosity, a Chinese coin of 1700 B.C.

The Institute.—Chief among the literary organizations of Paris is the Institute. It is installed in the ancient College Mazarin, or the College of the Four Nations, founded by Mazarin, situated on the left bank, at the end of the Port des Arts, opposite the Louvre. The building dates from the latter part of the 17th century, and stands on the site of the hotel de Nesle. During the Revolution it was used as a prison; but in 1795 it was ceded by the Convention to the Academies, or Societies of Savants, which had theretofore been housed at the Louvre. The Institute, which was created 25 Oct. 1795, embraces the five academies, namely, the Académie Française, founded about 1629 by Richelieu; the Académie des Inscriptions et Belles-lettres, founded in 1635 by Colbert; the Académie des Sciences, founded in 1666; the Académie des Beaux-Arts, founded in 1819; the Académie des Sciences Morales et Politiques, founded in 1666, but suppressed in 1803 and re-established in 1832. Each of these academies has 40 members, except the Academy of Sciences, which has 66, and all except the Académie Française have honorary, corresponding and foreign members. They are for the most part independent and separate bodies, but all five unite in an annual meeting "under the dome" on the 25th of October, which is one of the great literary solemnities of the Paris year. The Académie Française, the most distinguished of the five—its members being dubbed "the 40 immortals"—is charged with a superintendence of the language, the orthography and pronunciation, and with the publication and periodical revision of the *Dictionnaire de l'Académie* (last edition, 1878). The functions of the other four are sufficiently indicated by their names. The title "Membre de l'Institute," and especially the title, "de l'Académie Française," are objects of

the highest ambition of every literary man in France. No other country has so complete an organization of its literary and scientific men as the Institute de France, and nowhere else are the leaders of thought so bound together and so marshaled for concerted effort under one roof as in these five academies. Vacancies as they occur are filled by ballot of the surviving members, each of the academies for itself, subject to the approval of the government. No one is eligible except French citizens, but they need not be native born citizens. They must, however, live in Paris.

Assistance Publique.— Assistance Publique in Paris dates from the tax which Louis XIV imposed, in 1677, on the gross receipts of the theatres for the benefit of the hospitals and asylums. This tax exists to-day and for the same purpose. Until about 75 years ago it was paid personally by each person who entered the theatre as he bought his ticket, but at a separate window established for the purpose. Now it is 10 per cent of the price of the ticket and is assessed against the theatre itself. Numerous hospitals and asylums existed in Paris during the Middle Ages. The principal one was always the Hotel Dieu, and it is still the first of Parisian hospitals. It is situated on the island of the city near Notre Dame. The present building was erected in 1868-78 at a cost of 45,000,000 francs. It is admirably fitted up with 828 beds. It is said to be the oldest hospital in Europe, having been founded in 660 A.D. under Clovis II. There are about 20 other general public hospitals in Paris, which have an aggregate of upward of 33,000 beds; among which may be mentioned La Pitié near the Jardin des Plantes, with 729 beds; the Charity Hospital, a large and ancient institution in the rue Jacob, and the military hospital of Val de Grace in the Latin quarter, formerly a Benedictine convent founded by Anne of Austria, but converted by Napoleon into a hospital for soldiers. The church connected with it, formerly the convent chapel, is a splendid building, being a reduced copy of Saint Peter's at Rome. The dome, 53 feet in diameter and 133 feet high, is one of the most conspicuous monuments of the left bank. Among the numerous asylums, the most notable is the Salpêtrière, undoubtedly the largest such institution in the world. It is situated near the Pont d'Austerlitz on the left bank, and was originally an arsenal built by Louis XIII, which was subsequently converted into an asylum for aged and insane women. It consists of 45 huge buildings, having in the aggregate no less than 4,682 windows. There are 8,000 inmates. It is associated with the reform brought about in the treatment of the insane by Philippe Pinel, whose statue stands in the Place in front. There is a similar home for aged and infirm men at Bicêtre, and there are numerous institutions for the care of children and for the treatment of special diseases. The number of patients annually received and cared for in the hospitals amounts to about 50,000 men and 40,000 women and 20,000 children. The average annual deaths are about 7,000 men, 5,000 women and 3,000 children. The Assistance Publique expends annually about 40,000,000 francs on these hospitals and other allied charities.

The Hotel des Invalides.— This great institution was founded in 1670 by Louis XIV as

an asylum for his aged and disabled soldiers. With its high gilded dome, under which are the tombs of Napoleon, Turenne, Vauban, Jerome and Joseph Bonaparte and Marshal MacMahon, it is one of the most conspicuous monuments of Paris. The buildings, which cover about 30 acres, were begun in 1671 and completed in 1675. They furnish accommodation for 6,000 inmates. The façade of this vast structure is 660 feet in length. It stands about 600 yards back from the Seine, facing the Esplanade des Invalides, a fine open place about 900 feet wide, containing several rows of trees and extending to the river opposite the Champs Elysées. Close by is the Military School (*Ecole Militaire*), another great block of buildings covering 26 acres, the façade of the main building being about a quarter of a mile long. It was founded by Louis XV in 1751. There are about 500 students, the greater part of the establishment being now used as a caserne. It faces the Champ de Mars—another great open square, 1,100 yards in length and 550 yards in width, extending to the river, opposite the Trocadéro—which was originally designed for military manoeuvres, and was the site of many imposing ceremonies and pageants during and immediately after the Revolution. The Tour Eiffel is built on the end next the river. It is a full 1,000 feet high (1,062 feet to the very top), being thus the tallest monument ever erected, nearly twice as high as the monument at Washington, and more than twice as high as the Great Pyramid. Commencing in 1867, some of the buildings of the International Expositions have been built on the Champ de Mars. It has, however, recently been condemned and is to be laid out in streets and built up in the near future. The Ministry of Foreign Affairs, one of the handsomest government buildings in Paris, adjoins it on the east along the Quai d'Orsay.

The Cemeteries.— There are more than 20 cemeteries in Paris, but at present much the greater number of interments are made in the newer cemeteries without the walls. There are, however, but three within the city of any considerable size or of much general interest. The largest and finest is Père Lachaise (*Cimetière de l'Est*), situated prettily on a hill, in the northeastern part of the city, commanding a fine view. It takes its name from Lachaise, the Jesuit confessor of Louis XIV, whose country seat formerly occupied the site. It dates only from 1804, and extends to but 110 acres, but it contains the graves and tombs of a great number of the most distinguished Frenchmen of the last 150 years. Many also of a much earlier date have been moved there, as, for example, the tombs even of Héloïse and Abelard. It well repays a visit, and some careful study. Next in interest is the cemetery of Montmartre (*Cimetière du Nord*), situated in the northern part of town not far from the Church of the Sacré Cœur. The cemetery of Montparnasse (*Cimetière du Sud*), on the left bank, dating from 1824, is the third in interest of the Parisian burying grounds. It is not far from the Gare Montparnasse. The little cemetery of Picpus, near the Place de la Nation, in the garden of an ancient convent, contains the graves of many distinguished people of the Revolutionary epoch. It is of especial interest to Americans as containing the grave of La-

fayette. These cemeteries are all much alike in appearance, and in general much resemble those of New Orleans, the greater part of the tombs being above ground. There is a crematorium at Père Lachaise—the only one in Paris—with a columbarium in the Italian style as a depository for the ashes of the persons cremated there.

The Fountains.—After Rome no city is richer in fountains than Paris. There are dozens of them throughout the city, many of which are veritable works of art, and quite entitled to mention in any attempt to present a general view of Paris. The two large and beautiful fountains in the Place de la Concorde, constructed in 1836, contribute very much to the brilliance of that finest of Parisian squares. They each consist of a round basin 53 feet in diameter, above which rise two smaller basins surmounted by a spout from which a jet of water rises 28 feet in the air. The lower basins are surrounded by tritons and nereids, holding dolphins, which spout water into the second basins. The figures and the upper basins are bronze and the lower basins granite. These fountains produce a volume of spray, which under bright sunlight is superb. Two handsome modern fountains in granite ornament the Place du Theatre Français. Another of the great fountains is that of Saint Michel in the Place of the same name. It was constructed in 1860 and is 84 feet high and 48 feet wide, built into a wall. It consists of a niche in the form of a Roman triumphal arch containing a group of Saint Michael and the dragon in bronze mounted on a pile of rock, from which water gushes into three basins one above the other, flanked by bronze griffins of heroic size. At the sides of the niche are columns of red marble bearing bronze figures. The whole, though open to criticism in detail, constitutes a very imposing monument. The fountain of the Observatory, constructed in 1874, is a striking and original work, in the fine avenue of the Observatory with its six rows of forest trees. This fountain consists of eight sea horses, a group of four allegorical figures bearing an armillary sphere and water-spouting dolphins and tortoises. The basin is 60 feet in diameter and a great volume of water is discharged into a square reservoir below the basin, with a fine effect. The fountain of Saint Sulpice was erected in 1847 in front of the church of that name and consists of three concentric basins of stone one above the other and is embellished with statues of heroic size of the four most celebrated French preachers: Bossuet, Fénelon, Massillon and Fléchier. The volume of water is not great, but the fountain is a dignified and handsome ornament to the square. The fountain Molière, erected in 1844 to the memory of the famous dramatist, stands on the rue Richelieu near the house where he lived and died. It is 51 feet high and 21 feet wide, with a bronze statue of the poet flanked by the muses of serious and light comedy. Nearby in the same street in the small square Richelieu, facing the Bibliothèque Nationale, is the fountain Richelieu, in bronze, dedicated to the four great rivers of France. It stands on the site of the old Grand Opera, to wash away the stain of the assassination of the Duke de Berry in 1820, who met his death there, under very tragic circumstances. The fountain de Grenelle in the street

of that name near the rue de Bac, erected in 1739, is one of the finest of the old fountains. It consists of a crescent 100 feet in diameter and 38 feet high, in the centre of which stands a small Ionic portico with an allegorical group in white marble representing the city of Paris with the Seine and the Marne. Alfred de Musset died in 1857 in the house in front of which the fountain is built. The two fountains in the Jardin du Luxembourg—the old fountain de Médicis and the new one in memory of Delacroix—the ancient fountain of the Innocents at the central markets, and the splendid fountain de la Victoire in the Place du Chatelet, erected in 1807 to commemorate the earlier victories of Napoleon, are each of them notable monuments. A mention of the wonderful fountains at Versailles (*“les grandes eaux”*) incomparably the finest in the world, completes the general view of the fountains of Paris.

The Seine and the Bridges.—No single feature gives to a visitor a stronger suggestion of the imperial splendor of Paris than the installation of the Seine. The river, which flows for a distance of between seven and eight miles through the city, is contained within high walls of the most massive masonry. On either side of the river from one end to the other there is a broad street, lined with trees, and next to the river on the quai is a sidewalk or pavement. Below the quais and near the level of the water are the ports, also of masonry, where boats can land and freight and passengers be received and discharged. The walks along these shaded quais, with the river on one side and the busy life of the street on the other, are among the most interesting promenades in Paris. The bookstalls on the quais have long been famous. Passenger steamboats (*bateaux mouches*) ply up and down the river, making stops every few blocks and affording an excellent service for a fare of two cents at all seasons of the year. The 33 bridges which cross the river within the fortifications are among the most attractive features of the city, several being imposing works of art. The viaduct bridge at Auteuil is a mile and a quarter long, constructed throughout of masonry, with several galleries for vehicles and foot passengers beneath the railway line, and consists of 234 cross arches. It is a structure of exceptional beauty. The most famous of the bridges is perhaps the Pont-Neuf, which spans the river across the lower end of the island of the City. It is one of the oldest of the bridges, having been first constructed across both arms of the Seine in 1578. On the island, half way across the bridge, rises the equestrian statue of Henry IV. More traffic passes over this bridge than any other bridge in Paris, and perhaps more than over any other bridge anywhere, except possibly the congested traffic over London bridge. The Pont-Alexandre III is the newest of the bridges and was one of the notable contributions of the Exhibition of 1900 to the adornment of the city. It is a single steel span crossing the river so as to connect the Champs Elysées and the Esplanade des Invalides, affording a direct passage from the Palace of the Elysée to the Hotel des Invalides. Other notable bridges are the Pont de la Concorde, which at the time of the destruction of the Bastille was paved with some of the stones of that famous prison: the Pont d'Austerlitz, a massive

work of masonry, recently widened, which after the Pont-Neuf is the most traveled of the bridges, connecting the two great railway stations, the Gare de Lyon and the Gare d'Orléans; the Pont Notre-Dame and the Petit Pont, which cross the two arms of the river at the island of the City in the line of the rue Saint Jacques and the rue Saint Martin, being thus situated precisely at the places of the first Roman bridges that crossed the river; the Pont des Arts, which is the only bridge in Paris which is simply a foot bridge, connecting the Institute and the Louvre; the Pont au Change at the Chatelet and the Pont Saint-Michel at the Place of that name, which are beautiful specimens of the art of bridge building in stone. By means of locks and dams the river is kept at all stages of water at about the same height, the minimum depth being $10\frac{1}{2}$ feet; so that boats of 800 tons burden can come to Paris from Havre. This, in connection with the extensive system of canals of northern France which centre in Paris, makes of the capital the second port of the country. It is equaled in tonnage only by Marseilles.

The Parks.—Paris is one of the most favored of cities in the matter of parks. Although necessarily within the fortifications the area of parks and open spaces is relatively limited, there are within and without the walls—but within easy distance—including Fontainebleau and Versailles, about 200,000 acres of public parks, of which 20,000 acres are within 30 minutes travel from the centre of the city. The Bois de Boulogne and the Bois de Vincennes are the two largest strictly urban parks, the former being the most thronged and fashionable park in the capital. It extends to upward of 2,250 acres and lies between the western fortifications and the Seine. It was laid out in 1852, and since that time it has become the promenade not only of all Paris, but of all Europe. It is most frequented between 3 and 5 o'clock on summer afternoons. There is also a morning hour from 9 to about 11, when many "smart" people drive and ride. The Hippodrome de Longchamps in the Bois de Boulogne is the principal race course in the neighborhood of Paris. Races take place there almost every day, in spring, summer and autumn. The *Grand Prix* is run on a Sunday at the beginning of June and is the greatest racing event of the year in Paris. The value of the stakes at the *Grand Prix* is usually between 350,000 and 400,000 francs. Thus in 1913 it was 359,757 francs, plus 20,000 francs to the breeder. In 1914 it was 358,000 francs plus the same 20,000 francs. This is the most valuable stake in the world. The Bois de Vincennes is on the other and less fashionable side of the city, and is not as frequented as the Bois de Boulogne. It is the forest in which Louis IX used to hunt and administer justice. It also contains about 2,250 acres. The other principal parks within the city are the Jardin du Luxembourg—a beautiful garden, in the Latin quarter, in the style of Le Notre; the Jardin des Plantes, dating from 1640 in the reign of Louis XIII, with its museums of natural history and zoology made famous by the labors of Cuvier and Buffon; the Champs Elysées, most famous of city promenades; the Parc Monceau, in an aristocratic quarter, anciently the property of the dukes of Orléans; the Parc

de Montsouris, one of the most picturesque pleasure grounds in any city; the Parc des Buttes Chaumont, in a neglected quarter of the city, on the site of the ancient gallows or gibbet of Montfaucon, where from about 1273 until the Revolution an uncounted multitude of malefactors were hanged; and finally the Jardin du Palais Royal and the Jardin des Tuileries in the very heart of the town. The boulevards are lined with trees—some of the wider streets having four or more rows—and many gardens in the courts throughout the city contain fine clumps of trees, so that on a bird's-eye view, as from the top of the Tour Eiffel, Paris seems almost to be built in a forest. There are, within the fortifications, nearly 400,000 trees under municipal supervision.

The Exhibitions.—Chief among the annual exhibitions in Paris is of course the Salon. It is held in the spring in the Grand Palais and is the principal artistic event of the year. Ordinarily about 2,000 paintings and 1,000 pastels, water-colors, etc., are shown, in addition to the sculpture and the bronzes. It attracts artists and lovers and patrons of art from every part of the world. The Concours-Hippique, also held in the Grand Palais, is the Paris Horse Show. It dates from the early days of the Second Empire, and is the model upon which such shows elsewhere have been organized. It, too, is held in the spring. The agricultural show in the Galerie des Machines is what its name indicates—an exhibition of agricultural machinery, farm products, cattle and pedigree stock, horticultural productions, dairy products, poultry and wine. It is an annual fair. The culinary exhibition, which is held in midsummer in pavilions erected for the purpose in the gardens of the Tuileries, is a curious show, intended to promote competition and excellence among cooks and to stimulate effort in culinary matters. The *Foire au Pain d'Epice* (gingerbread fair) is held in the Place de la Nation for the four weeks following Easter. It is the fair of the common people, with side-shows and merry-go-rounds and the like. It attracts enormous crowds, and is an interesting sight for visitors. The automobile shows, which for several years have been held in the winter at the Grand Palais, are notable events for persons interested in that industry. They attract the *haut monde* or "tout Paris," as the phrase is, and like the horse shows are almost as much social functions as exhibitions. International exhibitions have been held in Paris in 1855, 1867, 1878, 1889 and 1900; Paris may accordingly be said to be the home of the international exhibition. In 1900 there were 50,860,000 admissions to the exhibition—an unparalleled attendance. A great general international exhibition in 1921 to celebrate the semi-centennial of the republic has been proposed.

The Monuments.—First, perhaps, among the monuments that adorn the city is the Arc de Triomphe de l'Etoile, which stands in the spacious Place de l'Etoile, on an eminence at the head of the avenue des Champs Elysées. From this arc radiate 12 great avenues, like the spokes of a wheel, chief among which, after the avenue des Champs Elysées, are the avenue du Bois de Boulogne; leading to the park, and the avenue de la Grande Armée leading to Neuilly. This famous monument is the largest triumphal arch in existence. Its height is 160

feet, its width 146 feet and its depth 72 feet. The names of 172 victories of Napoleon and of 386 of his generals are carved into the arc, which consists of a main arch 67 feet high and 46 feet wide, intersected at right angles by a lower transversal arch. The work was begun by Napoleon in 1806 and finished by Louis Philippe in 1836. It is adorned with colossal trophies 36 feet high, with figures 16 feet high, its cost having been about 2,000,000 francs.

The Arc de Triomphe du Carrousel in the gardens of the Tuileries, built by Napoleon to commemorate his victories of 1805 and 1806, in imitation of the Arch of Severus at Rome, and formerly the chief entrance to the Palace of the Tuileries, is a notable structure. It was originally crowned with the celebrated Quadriga from the portal of Saint Mark's in Venice. Somewhat similar to these in general character are the Porte Saint Martin, in the grand boulevard—a triumphal arch 57 feet in height, erected in 1674 in honor of Louis XIV; and the Porte Saint Denis, another triumphal arch near by in the same thoroughfare, consisting of a single archway, 81 feet in height, built to commemorate the victories of the grand monarch in the Low Country. These two monuments are all that remain of the wall of Louis XIV, which was pulled down by Louis XV to make place for the grand boulevard.

The tomb of Napoleon under the dome des Invalides is a magnificent mausoleum, the tomb itself consisting of a sarcophagus of reddish-brown granite from Finland, weighing 67 tons, and being 13 feet long, 6½ feet wide and 14½ feet high. With its superb setting under the fine dome, it constitutes a most impressive memorial.

The Pantheon is in some respects the most imposing public edifice in Paris. It stands on the highest ground on the left bank on the site of the tomb of Sainte Geneviève, the patron saint of Paris. It was built by Louis XV (1764-90) from plans by Soufflot, and was designed to be the church of Sainte Geneviève. But in 1791 the Convention converted it into a sort of memorial temple, naming it the Pantheon, and inscribing on its front the words: "*Aux grands hommes la patrie reconnaissante.*" It is of most imposing appearance and dimensions, in form a Greek cross with equal arms, 370 feet long and 276 feet wide, surmounted by a dome 272 feet high and more than 75 feet in diameter, the lantern at the top of which is reached by a staircase of 425 steps. A huge colonnade consisting of 22 fluted Corinthian columns 81 feet in height, resembling that of the Pantheon at Rome, forms the portico, to which 11 steps ascend. The tympanum, 117 feet long and 23 feet high, contains a fine group of sculpture by David d'Angers. Mirabeau was buried here in the spring of 1791; shortly afterward Marat, Voltaire and Rousseau, and more recently Victor Hugo and President Carnot. The bodies of Voltaire and Rousseau were removed at the Restoration. The vaults also contain a considerable number of tombs of distinguished officers and soldiers of the Revolutionary period. The government is slowly decorating the interior with works of the best contemporary artists.

The Palais du Trocadéro, on the elevation in Passy, opposite the Champ de Mars, upon which Napoleon planned to erect a palace for

the king of Rome, is a huge building in the oriental style. It consists of a circular edifice 190 feet in diameter and 180 feet high, surmounted by a dome and flanked by two minarets 270 feet high. On each side extend wings, 660 feet each in length, the whole in the form of a crescent. The main building contains a Salle des fêtes with an immense organ, and has seats for 6,000 persons. This is the largest auditorium in Paris. The palace contains important museums of comparative sculpture and ethnography.

Mention ought also to be made of the Palais Royal with its garden, built and owned originally by Richelieu (1629-34), where he lived at the end of his life and where he died in 1642, but it was thereafter long the property of the dukes of Orleans. The cafés and gardens of the palace were, during the Revolution, the rendezvous of democrats and malcontents generally. It was here that Camille Desmoulins called the populace to arms in July 1789. It is now government property and the seat of the *Conseil d'Etat*. A proposition has been made on behalf of some American merchants to convert a part of the arcades surrounding the garden into a great American department store, or general magazine for the exploitation of American goods, wares and merchandise. The Palace of the Order of the Legion of Honor, instituted by Napoleon in 1802, is situated on the Quai d'Orsay, at the corner of the rue Solferino. It was burned in 1871 by the Commune, but has been handsomely rebuilt. The original building was erected in 1786, and was interesting as the scene of Mme. de Staël's reunions during the Directory.

The Column Vendôme, 142 feet high and 13 feet in diameter, constructed from German cannon captured in the Napoleonic wars, surmounted by the bronze statue of Napoleon as a Roman emperor, stands in the centre of the Place Vendôme. It is one of the conspicuous monuments of the city. The column of July in the Place de la Bastille, erected by Louis Philippe, in 1831, celebrates the heroes who fell in the Revolution of 1830. It is 154 feet high and affords from its top a fine view of that part of the city, particularly of the cemetery of Père-Lachaise.
